If these structures have evolved in aquatic flowering plants because they increase search efficiency, one would expect that unrelated organisms with similar search problems would also have structures that are alike. Called convergent evolution, the development of similarities in unrelated organisms is frequently good evidence of adaptation. Many flowering plants in African deserts, for example, are superficially very much like the American cactus plant. Even though they are evolutionarily unrelated, both types of plants produce fleshy, round green stems covered with spines. Their resemblance suggests that a succulent cylindrical form, armored with spines, is an adaptation to desert conditions since it occurs in completely unrelated desert plants. Thus if a group of organisms unrelated to aquatic flowering plants but possessing similar search problems were found to have similar dispersal forms, this would be strong evidence that elongated pollen shapes are indeed adaptive.

Accordingly, I examined spores in the Hyphomycetes, a group of terrestrial and aquatic fungi. The aquatic members have a search problem somewhat analogous to that faced by flowering plants with water-mediated pollination systems. The spore of an aquatic fungus must travel through the water to find, not a stigma, but a host of living or decaying organic matter in which it can germinate. In both cases, the search is for a relatively fixed target. Have the fungi and the flowers evolved along similar lines?

Indeed, large, unusually shaped spores are common among aquatic fungi. In aquatic hyphomycetes, mycelia—threadlike fungal tubes—branch inside of the host tissue, and organs from which the spores are liberated project into the water. The spores of these aquatic organisms are either long, threadlike, and S-shaped or they are tetraradiate (four-pronged) structures, with long arms branching from a single point. The tetraradiate spores of *Actinospora* are nearly thirty-eight times the mean diameter of their terrestrial counterparts.

Even stronger evidence of evolution toward efficient search is provided by a single species of aquatic fungus that produces both aerial- and water-dispersed spores of different sizes or shapes. John Webster, of the University of Exeter, has described just such a situation in species of the genus *Entomophthora,* in which the spores are egg shaped if dispersed aerially but tetraradiate if they are dispersed underwater.

Like aquatic pollen that sprouts prematurely, some fungal spores germinate before they encounter their hosts. In these fungi, the search vehicle is the spore plus one or more long germ tubes. Other structures also widen the search vehicle. The marine fungus *Nia vibrissa* produces long appendages on its spores before dispersal. Just as solar panels slowly unfold from a satellite once it reaches its orbital position, so the gelatinous membranes of spores of the fungus *Pleospora lignicola* expand upon contact with water, forming three blunt arms that greatly increase its effective search width.

These unusual shapes and sizes may serve other functions as well. Filamentous or tetraradiate shapes may—like grapnels or bolos—more easily anchor to their targets once contact is made. Some botanists have suggested that elongate sea grass pollen may wrap around the stigmas, while the arms of tetraradiate fungal spores anchor them to their host's tissue. Experiments indicate that tetraradiate fungal spores are trapped more frequently by underwater surfaces and air bubbles than are spherical spores. These theories pertain more to aquatic spore shape than to size; a combination of search and "anchoring" hypotheses may be required to explain the structure of aquatic spores.

Just as physicists and mathematicians have learned from Brown's observations of pollen grains in water, so botanists stand to learn much about pollen and spores by considering the mathematics of random motion and random search. It seems fitting that the work of botanist Robert Brown—which began with pollen grains and spores and spawned such great advances in physics and mathematics—should now come full circle. □

Tiny male eel grass flowers sail toward the much larger female. Floating slightly below the surface, the female blossom creates a small depression in the water, into which the male flowers tumble. In effect, the whole male flower functions as a search vehicle carrying a cargo of pollen.

Derelicts and Drifters

Old abandoned sailing ships and new satellite-tracked buoys tell us where some ocean currents came from and where they're going

by Philip L. Richardson

As a child growing up in a small coastal town in northern California, I used to daydream about sunken wooden ships. I pictured them drifting endlessly through the water, each at a different depth. The ocean was layered, I thought, with these trapped, abandoned vessels. Years later, when I had become a physical oceanographer and moved to the Atlantic Coast, I learned that abandoned wooden sailing ships had indeed drifted in the ocean—but on its surface and not forever. In the late 1800s, sightings of these derelicts provided the first information on the paths of surface currents, particularly of the Gulf Stream, in the North Atlantic. For eight years I had been studying the Gulf Stream, using freely drifting buoys tracked by satellite, and I thought I was the first to assemble a sizable body of information on current trajectories in the North Atlantic. I was wrong. The earlier information, which had been forgotten in the last eighty to one hundred years, was also extensive and quite accurate.

The nineteenth-century derelicts that provided information on surface currents were wooden-hulled ships; those that stayed afloat the longest—for more than the average thirty days—were often schooners carrying cargoes of lumber. From the point of view of a ship's captain, any drifting derelict was a formidable hazard. A collision with such an object at night or in a fog could damage or sink a ship. Toward the end of the last century, the Atlantic Ocean was strewn with numerous abandoned schooners and barks in various stages of disintegration.

In December 1883, the U.S. Navy Hydrographic Office, a branch of the Bureau of Navigation of the Navy Department, began to publish monthly pilot charts for the North Atlantic that showed the positions of the abandoned ships—identified by name—and of other drifting debris. The charts were issued free to navigators in return for their reports of recent navigational and weather information. The pilot charts were successful because a large number of observers contributed information to them each month and because they were distributed rapidly to ships' captains.

In the late 1800s, more than 1,600 derelicts were sighted, and reports were collected from nearly 3,000 voluntary observers—mariners who crossed the North Atlantic and who patrolled its waters. These sightings provided information on the bifurcation of the Gulf Stream near the Grand Banks of Newfoundland and evidence of the variability of ocean currents. They also documented a tragic loss of life. Toward the end of the nineteenth century, 12,000 lives and 2,200 vessels were lost worldwide at sea each year. Every severe ocean storm left new derelicts in its path and added new names to the long list of vessels that left port but were never heard from again.

Most of the reported derelicts were found in the Gulf Stream off the U.S. coast. Because of the hazard they represented to other ships, they were sought actively, initially by U.S. naval vessels, later by revenue cutters—armed government ships used primarily to prevent smuggling. When sighted, the derelicts were towed into port or set on fire while still at sea. During 1887–93, forty-one derelicts were towed ashore and another seventy-six were set on fire. One was destroyed by torpedoes and ramming. Others continued to drift until they broke apart or became so waterlogged and encrusted with barnacles that they sank on their own.

This is a typical pilot chart report, written in July 1889:

Notable Derelicts in the North Atlantic
Of the many wrecks afloat this month in the North Atlantic Ocean, none has as interesting a history as the Italian bark "Vincenzo Perrotta." Abandoned September 18, 1887, this vessel has been represented graphically on every edition of the Pilot Chart published since that time. Her wonderful drift began in about latitude 36°N, longitude 54°W [south of Newfoundland, east of Cape Hatteras]; and on April 4, 1889, when last reported, she was about 60 miles north of Watling's island, in the Bahamas. She has thus made good a distance of about 1,400 miles in a general SW. by W. direction, in 1 year, 6 months, and 16 days. She has been reported 27 times in all, and when last seen had mizzenmast and about 10 feet of mainmast standing, foremast gone, end of jibboom broken off and port anchor on bow.

In addition to the derelicts, other debris was reported drifting in the North Atlantic. In December 1887, a large raft of logs broke apart while being towed from Nova Scotia to New York by the steamship *Miranda*. The raft, which weighed 11,000 tons and drew twenty feet of water, consisted of 27,000 tree trunks bound with chains into the shape of a cigar. The logs were spruce pilings meant for the construction of docks and the foundations of large buildings. On December 18, the towing steamship *Miranda* encountered a severe storm. Her fifteen-inch towing hawser parted and the log raft went adrift in the track of commercial navigation. Although a search was made for the raft within a week of her disappearance, only remnant logs were found scattered over a wide area, about 140 miles southeast of Cape Cod. No ship was reported

Sailors leave a derelict ship after completing preparations to blow it up. If not burned, towed, or otherwise removed, such vessels often drifted for months, presenting a danger to passing ships. Derelict ships became a rarity as iron and steel replaced wood as a shipbuilding material.

The Metropolitan Magazine (September 1911), The New York Public Library

lost because of the incident, but the German bark *Bremen* was in the area for five days and had her sheathing torn and her rudder damaged. This log raft was one of only two of its kind that appeared on the east coast; an earlier one had arrived safely in New York from Nova Scotia. Schooner owners and captains, whose livelihood was threatened by the use of such rafts, were delighted that they proved impractical.

Many derelicts remained afloat for more than half a year and were reported often enough to provide evidence of long and interesting ocean trajectories. Six drifted longer than a year—the schooner *Fannie E. Wolston* drifted for 1,100 days; the schooner *Wyer G. Sargent*, 615 days; the bark *Telemach*, 551 days; the bark *Vincenzo Perrotta*, 536 days; the schooner *Ethel M. Davis*, 370 days; and the schooner *James B. Drury*, 367 days. These abandoned ships traversed from 1,700 to 9,000 miles.

Although the paths of these long-lived derelicts differed markedly in detail, patterns of drift can be detected. Several ships moved eastward in the Gulf Stream until they reached 50°W (south of the Grand Banks of Newfoundland), where their paths diverged. Some continued eastward and crossed the Atlantic in an average of ten months, others drifted southward. Two made tight turns and drifted westward just south of the Gulf Stream. The *Wolston*, which drifted for three years, first floated south to 25°N, then westward in the North Equatorial Current to the Bahamas, and finally northeastward into the Gulf Stream again, crossing its earlier path. Two derelicts drifted erratically but in a generally southwestward direction through the Sargasso Sea and grounded on the Bahama Islands. Most derelicts looped as they drifted. The *Sargent* and the *Wolston* made large, 300-mile loops (southeast of the Grand Banks) within a period of ten months. Several other derelicts made frequent, smaller-scale loops.

Derelicts that first appeared near the coast between Long Island and Cape Hatteras usually drifted southwestward, following the inshore current until they reached Hatteras. There they entered the Gulf Stream and drifted eastward. In general, derelicts entered the Gulf Stream north of 30°N (Cape Hatteras) and moved eastward in the stream. In an area south of the Grand Banks, near 40°N, 50°W, the derelicts appear to have followed either of two divergent paths. Recent measurements have confirmed that the Gulf Stream splits into two bands near the Grand Banks. The first band extends northeastward into the eastward flowing North Atlantic Current, passing north of the Azores. The second extends southeastward and then joins the westward flowing North Equatorial Current. The general circulation indicated by the collected trajectories of the abandoned ships is a large, clockwise pattern split into two branches, one to the north and the other southwest of the Azores. Six derelict vessels moved southward between the Azores and Spain and Portugal.

The large-scale, long-term ocean circulation pattern is characterized by considerable current variability. The derelicts did not usually follow the general pattern smoothly; instead they drifted in convoluted trajectories that often crossed each other. The convoluted paths give an early

A detail of the U.S. Navy's pilot chart of the North Atlantic for March 1888 gives the locations and dates at which derelict ships were sighted. Schematic drawings indicate the conditions of the ships, for example, stern down, bottom up, or mast standing. The paths followed by some identified derelicts are shown by broken lines. Other symbols locate drifting buoys, steamship routes, fog belts, and other vital navigation information.

measure of medium-size eddies and of longer-period current fluctuations. We now know that the ocean is populated by energetic eddies that are usually much stronger than the mean currents (the average velocity of the currents). The importance of these eddies to the general circulation has been discovered recently, and they have been studied intensively. Because of these eddies, the mean circulation becomes recognizable only by averaging a great number of observations in space and time. In the Gulf Stream, the North Atlantic Current, and the North Equatorial Current, one clearly sees the general drift in spite of the eddies. In the Sargasso Sea, the trajectories are dominated by the motion of medium-size eddies. The eddies in the Gulf Stream region are important in driving the average flow and determining the character of the general circulation. They also drive a deep eastward flow under the Gulf Stream and a westward recirculation on both its sides.

One should be cautious, however, about ascribing all the motion indicated by the derelicts' trajectories to water movement. Derelict ships varied in size, weight, and the state of damage. Some were totally dismasted and filled to the gunwales with

Built in 1874, the schooner Alice Murphy *was caught in a violent storm in 1915, off the North Carolina coast. The captain and six crew members, who had lashed themselves to the mizzenmast, were rescued, but the waterlogged vessel went adrift in the Gulf Stream. This photograph may have been taken from a tug owned by a New York salvage firm that investigated the derelict. The burned-out wreck of the* Alice Murphy *was later sighted six hundred miles east of New York, where it had been carried by surface currents.*

Collection of W.J. Lewis Parker

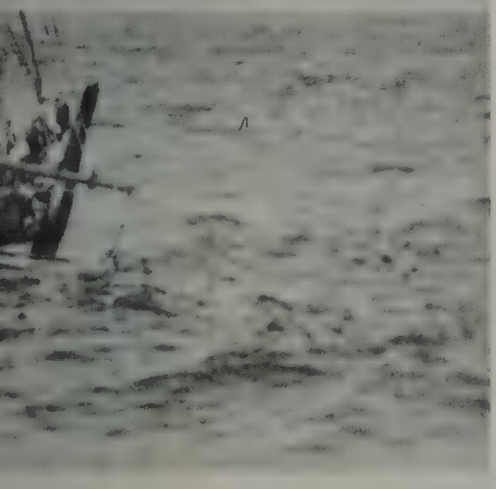
water. These, along with the 30 percent of the sightings of vessels that were turned bottom up, probably provided a good indication of the speed and trajectory of near-surface water. But derelicts with their masts standing and those riding high in the water were no doubt also influenced by wind blowing directly on the masts and the exposed hull.

Additional problems in the effort to interpret the trajectories accurately are position errors of the reporting ships, misidentification of derelicts, and infrequent sightings. The average number of days between sightings was about twenty—this is small enough to indicate some aspects of medium-scale eddies, but it is not small enough to resolve individual loops around the strong eddies, as do today's buoys. Nevertheless, the collection of the trajectories represents a realistic view of the general surface ocean circulation and the variability of currents.

In the nineteenth century, other information concerning surface currents came from ships under way. A ship's course and speed can be estimated in two ways: from its apparent progress through the water, and from its change in position on the earth's surface, as measured by ce-

In a 1965 painting by Gordon Johnson, the crew of the Dei Gratia *sights the* Mary Celeste, *found drifting off the coast of Portugal on December 4, 1872. Apparently the captain and crew had hurriedly taken to a lifeboat several days before; they were never seen again.*

The Atlantic Companies



lestial navigation. The difference, expressed in terms of set (direction) and drift (speed), is attributed to surface currents. Measurements of set and drift were first made in the late eighteenth century, after the introduction of chronometers had sufficiently improved the ability to determine positions at sea. As large amounts of data were accumulated, however, the huge numbers of observations became difficult to handle quantitatively. Therefore, most early summary charts of ship drift observations, such as those shown on the U.S. pilot charts, were schematic and qualitative. Only in recent years, with the advent of high-speed computers, have quantitative and statistical analyses of ship drifts been published.

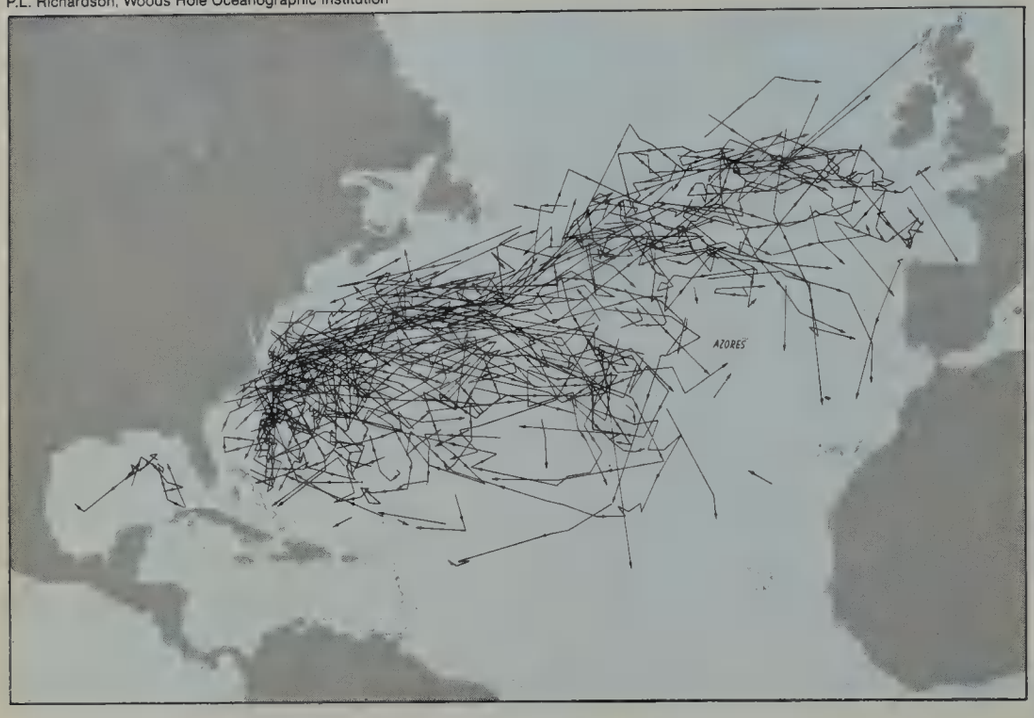
Because of the strong ocean variability, ship drift velocities taken individually or in averaged form do not provide a good measure of where the water actually goes. This key bit of information was provided by the drifting derelicts, which followed the water and provided long-term trajectories of water parcels. In this way the derelict trajectories complemented the measurement of ship drift velocity.

At the end of the nineteenth century, the number of drifting derelicts diminished rapidly. Relatively few derelict trajectories are found in the pilot charts after 1900. There were two major reasons for this decline. The first was the gradual replacement of wooden sailing ships with steam-powered vessels of iron or steel, a change that began in Britain. The second was the successful search for, and destruction of, derelicts by revenue cutters and naval vessels. By 1880, British steam tonnage superseded sailing tonnage, which was falling, and clipper ships could no longer compete with steamships as a means of fast transport. By 1900, the steamship had practically ousted the full-rigged sailing ship from every important trade route on the seas. The triumph of the steamship was a result of the introduction of iron hulls and steel hulls, the development of the screw propeller, and finally the triple expansion engine—a more efficient steam engine—which came rapidly into use after 1880. These developments resulted in stronger ships with more predictable speeds. The newer ships were abandoned less often, and those that were abandoned usually sank.

In America, the transition from sail to steam was more gradual than in Britain. Not until 1894 did American steam tonnage surpass sail in the coastal trade. Coastal sail tonnage continued to grow un-

The superimposed trajectories of drifting derelict ships and a few drifting buoys, as given by monthly pilot charts published between 1883 and 1902, reveal the large-scale pattern of North Atlantic surface currents. The surface water circulates in a clockwise direction, dividing into two smaller currents that move north and south of the Azores. Because of variations over time of the ocean currents, the paths of individual derelict ships often differed from one another or from the general pattern.

P.L. Richardson, Woods Hole Oceanographic Institution



til 1907, when it reached its absolute peak, representing 39 percent of the total coastal tonnage. By far the major part of this fleet of coastal sailing vessels was made up of wooden ships. A study of the casualty pages of the New Marine Register shows that a great many of these vessels continued to be abandoned waterlogged after 1900. But because of a more vigorous, systematic program of derelict destruction by revenue cutters and also by naval vessels, fewer wooden ships appeared as derelicts on pilot charts published after 1900.

The advent of wireless communication in the early twentieth century made locating a derelict at sea much easier. Positions of derelicts were sent by radio to the cutters so the derelicts could be found quickly and destroyed. Before this method of communication at sea, derelict hunting was at best a haphazard occupation. In 1907, a new revenue cutter, the *Seneca*, was built expressly for finding derelicts and destroying them or, if they were salvageable, towing them to port.

Today the large numbers of drifting buoys (sometimes called drifters) that measure ocean currents are tracked by satellite. The principal areas under study are the North and South Atlantic, the tropical Atlantic, and the tropical Pacific. The ocean's surface layer, directly forced by local winds, is only a thin skin over the mass of deeper water, which has a very different motion. In recent years, deep trajectories in the North Atlantic have been measured by high-tech drifters. These drifters, or floats, are constructed from aluminum tubes that are less compressible than seawater and are ballasted to sink to prechosen depths. Once there, they remain at those depths (like the wooden ships of my childhood reveries) as they drift. Because the ocean is relatively transparent to sound, the floats are tracked acoustically.

Known trajectories of nineteenth-century derelicts still outnumber those of today's buoys, but the newer measurements have the advantage of several fixes per day and a higher positional accuracy. From a collection of these contemporary measurements, we have been able to obtain a more quantitative picture of the general circulation and of the geography of ocean variability. Plots of the buoy trajectories show patterns very similar to those of the derelict trajectories. Although the derelict trajectories were made long ago by methods that now seem primitive, I believe they remain one of the best, if not the best, direct measures of the surface circulation of the North Atlantic. □

In a satellite infrared image of the Gulf Stream off the East Coast, differences in water temperature are coded by color. The purple band is the warm core of the stream; progressively colder temperatures are represented by red, yellow, light blue, and dark blue (white areas are clouds). The patterns reveal meanders and eddies in the Gulf Stream. Modern research techniques have confirmed and refined data gathered eighty to one hundred years ago from the observation of drifting derelict ships.

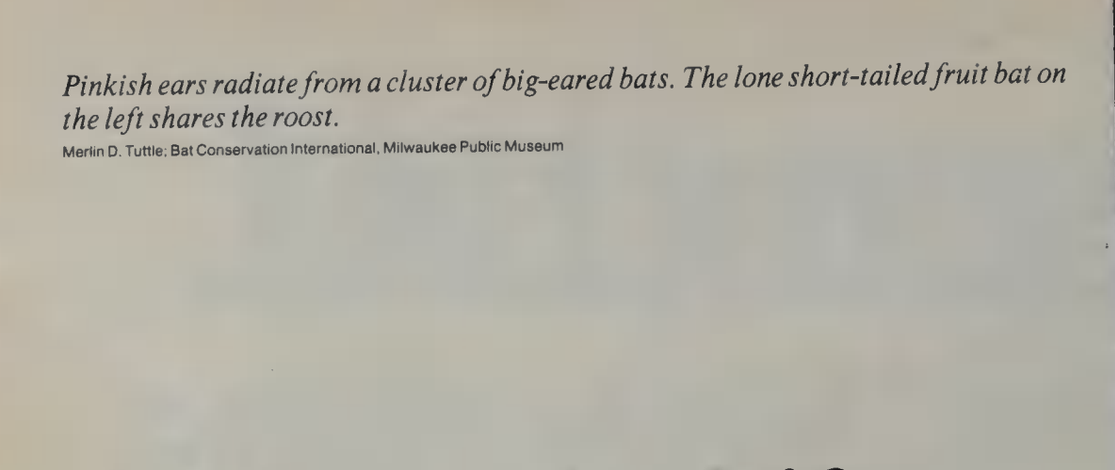
The Accord 4-Door Sedans



Pinkish ears radiate from a cluster of big-eared bats. The lone short-tailed fruit bat on the left shares the roost.

Merlin D. Tuttle; Bat Conservation International, Milwaukee Public Museum

A Day in the Life of a *Piper*-eating Bat

The exploits of a short-tailed fruit bat on a day that almost proved to be ordinary

by Theodore H. Fleming

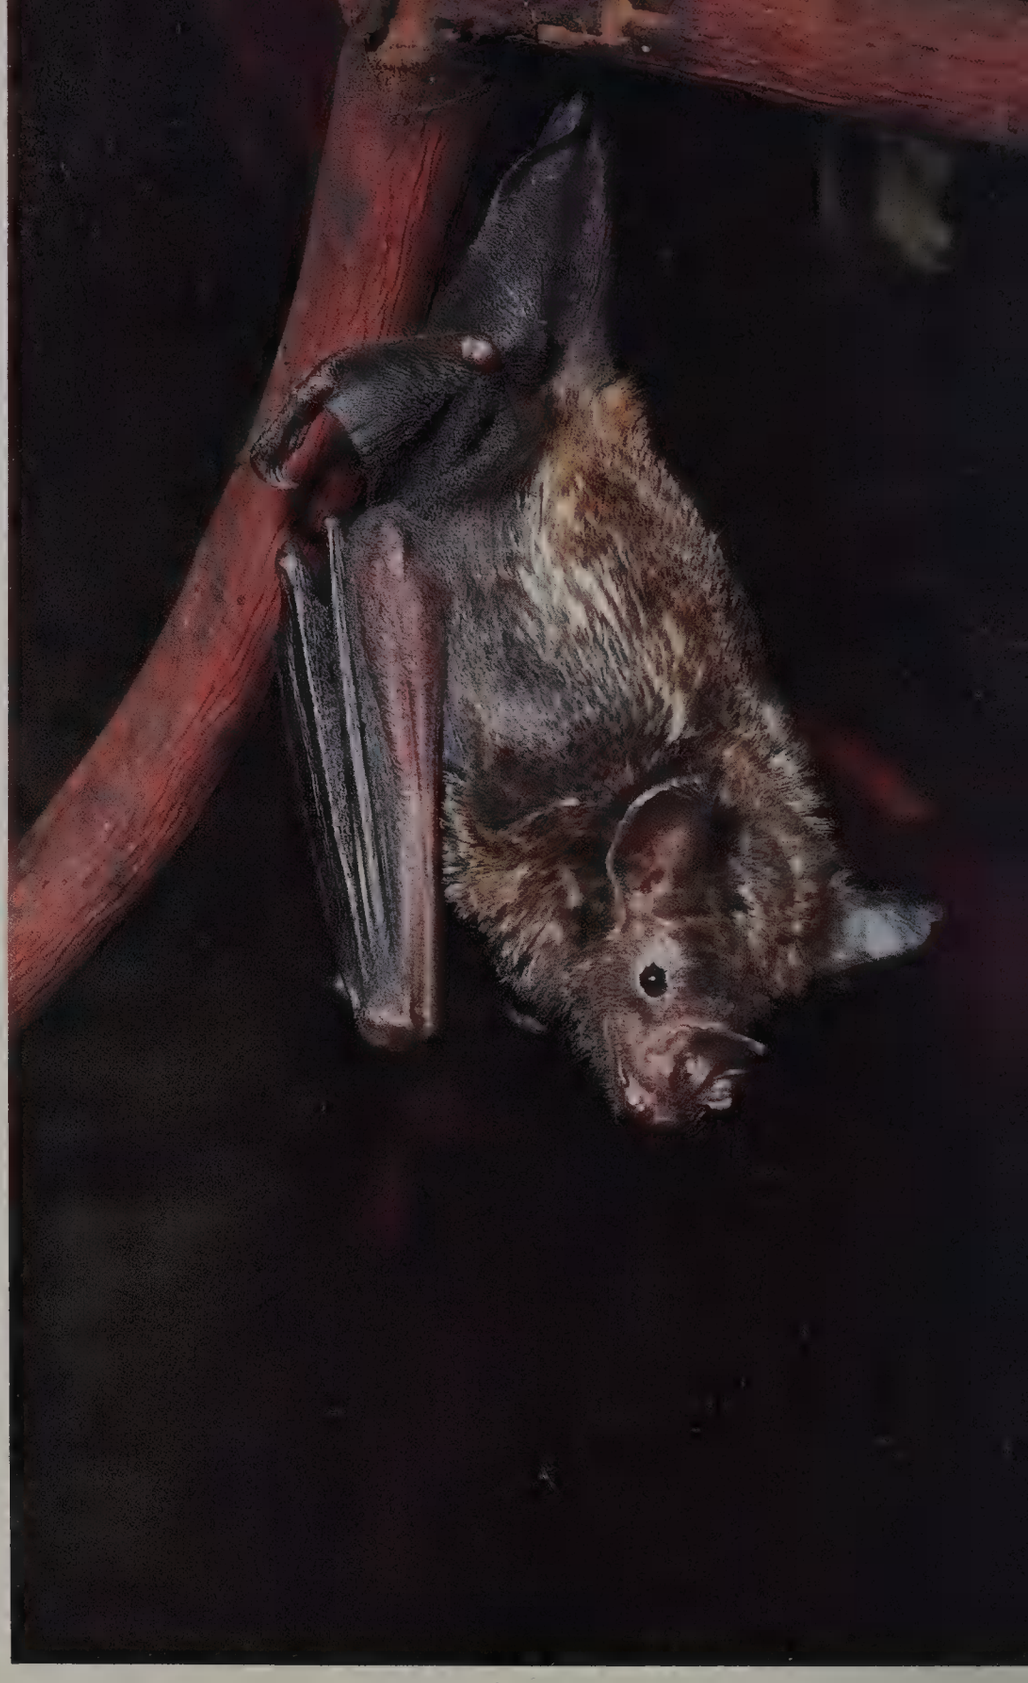
Five-fifteen on a morning in mid-July: the sun's first rays rush into the eastern sky, lighting up a trio of ancient volcanic peaks in western Costa Rica. Twenty-five miles west of the brightening peaks, first light is reaching a rocky stream bed known locally as the Quebrada El Duende (Will o' the Wisp Creek). At this moment, the last of a group of several hundred fruit-eating, flower-visiting bats are returning to a small cavelike tunnel that serves as their daytime roost. As these bats settle themselves on the cave's ceiling, the daytime residents of the creek bed and its surrounding forest are just starting their day. A plaintive *motmot motmot*, the call of a turquoise-browed motmot, echoes among the still-dark leaves, and a black-headed trogon sounds its rattling cry with monotonous frequency. From a nearby hillside, a male howler monkey roars, clearly proclaiming the location of his small troop of six adults and four young. Farther down the creek bed, a troop of white-faced monkeys crashes across the treetops, barking like dogs; they are heading upstream to eat the fruit of some *Cecropia peltata*, or trumpet trees, directly above an entrance to the bat cave.

By 5:30, the five species of bats in the cave have begun their thirteen-hour rest period. Their refuge is a well-illuminated tunnel, eighty feet long and two and a half to seven feet high, formed thousands of years ago by the creek's constant etching away of soft volcanic rock. Among the mass of bats lining the ceiling is a certain female bat—call her a composite of the many bats known to live in the cave.

She is a short-tailed fruit bat known scientifically as *Carollia perspicillata*. Weighing two-thirds to three-quarters of an ounce, *C. perspicillata* bats are medium-sized members of the family Phyllostomidae, the New World fruit bats. Like most others in its family, *C. perspicillata* possesses a nose leaf (a triangular flap of skin directly above its nostrils), which serves as a reflector, helping it direct its low-intensity, nasally emitted ultrasonic echolocation calls. Bats use these calls to communicate with each other, among other things. The short-tailed fruit bat has relatively large eyes (for a bat) and keen vision. Keener still is its sense of smell, which it uses to find ripe fruit. Our bat is chocolate brown, the typical color of this species. Not all the short-tailed fruit bats in this cave, however, are brown; a few are orange-red.

During the day, the female bat hangs by one foot from a tiny projection of the cave's ceiling, alternately sleeping and grooming her fur. Like most other bats, this short-tailed fruit bat grooms herself assiduously, scratching herself rapidly with the claws of her free foot. Periodically she cleans her grooming foot, licking it with the purposefulness of a cat. With this foot, she can reach all parts of her body, including the top of her head. She cleans her wing and tail membranes by licking them.

Although the Duende cave contains nearly equal numbers of male and female short-tailed fruit bats (seventy-five to one hundred of each sex), the two sexes generally segregate themselves into small,



During thirteen hours of daytime roosting, a short-tailed fruit bat hangs by one foot, leaving the other free for grooming sessions, which alternate with periods of sleep. Bats usually do their roosting inside caves or hollow trees.
Doug Wechsler

tightly packed clusters. The females gather near the center of the cave roof. Each group contains two to fifteen females and can be called a harem because it is guarded by a single adult male. Most of the males roost as "bachelors" in a darker, peripheral portion of the cave. Bachelor males are young (usually one to three years old) and have little or no chance of mating with females until they can gain access to a harem, either by fighting with and displacing a current harem male or by quickly taking the place of a harem male that disappears.

Our bat roosts in a tight cluster with ten other females and hence is a member of one of the largest harems in the cave. Her harem male is six years old and has controlled three harems, each bigger than the last, in the past two years. By now he has won many brief but intense boxing matches with other males intent on overthrowing him. The females he guards are a mixed group in terms of their ages and places of birth. About half of them are less than two years old.

As a five-year-old, our female is a relatively old bat; few in this population reach age eight. And unlike most of the females around her, she was born in another cave, two miles away. She remained there for nearly a year, and during this period her fur was bleached orange-red by urinary ammonia fumes in the poorly ventilated cave. Soon after moving to the new cave, however, the female molted and her coat grew in brown. Both male and female bats sometimes leave their natal homes and settle in other roosts before reaching adulthood. The migration rate between the several widely scattered caves in this part of Costa Rica is high enough to create a genetically homogeneous population of *C. perspicillata*.

Our bat has a distinctly swollen abdomen because she is pregnant with a single large embryo. When its four-month gestation period is over, her baby will weigh about a fifth of an ounce—or 25 percent of her mother's weight. After the baby is born in early August, it will nurse for about a month. During its first two weeks, it will cling to its mother's chest and nurse even when she is foraging away from the roost at night. When the baby becomes too large to carry, the female will leave it in the cave roost or in a tree away from the cave while she searches for fruit.

This is her second pregnancy this year. Most female short-tailed fruit bats give birth twice a year, once in late March or early April, just past the middle of this region's six-month dry season, and again about four months later, toward the middle of the wet season. The timing of births coincides with the two annual peaks in fruit growth in this strongly seasonal habitat. Once a mother stops nursing her baby, she has relatively little contact with her offspring, although daughters are likely to remain in their mother's harem for some time before joining another harem in the same cave or another cave. Males leave the harems at an early age and join bachelor groups, usually in their natal caves.

It is now just past noon, and the sun has passed its zenith. The cave is still comfortably cool, although the outside air temperature is nearly 92 degrees Fahrenheit. The air is still and heavy, a sure sign that an afternoon shower is approaching. The area that shades and surrounds the creek bed is tropical dry forest. During the dry season, most trees lose their leaves, and

Prompted by the heavy rains of late spring, the tropical shrub Piper amalago, *below, a staple and favorite food of short-tailed fruit bats, produces fruiting spikes. The plant depends upon bats for seed dispersal. Bats seize the high-protein fruit while on the wing and may carry it some distance through the forest before stopping to eat. The seeds consumed with the fruit are quickly excreted, often at the feeding site.*

T.H. Fleming

from February through April, the forest floor is covered with a thick carpet of dry leaves. In moister places, the common understory shrubs are nondeciduous members of the genus *Piper* (family Piperaceae). Five species inhabit this region of Costa Rica. *Piper* shrubs play a particularly important role in the life of *C. perspicillata*, for the bats are partial to their fruit. Although *Piper* fruit generally have no commercial value, the seeds of one species, *P. nigrum*, are used worldwide as black pepper.

In mid-July, the fruit of *P. amalago*, a multiple-stemmed, six- to nine-foot shrub, are beginning to ripen; the seeds are dispersed exclusively by four species of bats. As is true for all dry forest plants, *P. amalago*'s flowering and fruiting biology is strongly tied to seasonal changes in rainfall. During most of the dry season, these shrubs bear immature inflorescences—spikes with flowers up and down their length—that emerge near the tips of the upper branches. As soon as the wet season begins, in late April to mid-May, the inflorescences start to lengthen, eventually becoming spikes 1.5 to 2.4 inches tall bearing several hundred tiny flowers. Two to three weeks after the rains begin, *P. amalago* will be in heavy flower, and its white inflorescences will be visited by a diverse array of pollen-collecting insects, including stingless bees, sweat bees, leafcutter bees, and syrphid flies. These insects play a crucial role in moving *P. amalago* pollen among the inflorescences. If insects don't visit the *P. amalago* shrubs, they produce very little fruit; if pollinated, each flower on the spike will produce a single-seeded fruit. Generally, each spike bears one hundred to two hundred fruit. As it matures, the fruiting spike (hereafter called a fruit) turns green and resembles a small sweet pickle.

P. amalago is only one of three *Piper* species whose growth is stimulated by the rainy season. Because of differences in inflorescence length or growth rates, the other two species, *P. pseudofuligineum* (which has inflorescences about three inches long) and *P. jacquemontianum* (which has thicker, slower-growing inflorescences), flower later in the first half of the wet season. The slight differences in scheduling allow these three *Piper* species to share their pollinators without too much competition. The other two species, *P. marginatum* and *P. tuberculatum*, have flowering (and fruiting) periods that also differ from the others. *P. marginatum* flowers after a brief spell of dry weather that usually occurs in July, and *P. tuberculatum*, a creek side species, flowers in March and April during very dry weather. All in all, the five *Piper* species supply *Carollia* and other bats with a continual and reliable food supply for several months each year.

This year's wet season began in mid-May, so the fruit of *P. amalago* are just ripening. The crop of each plant ranges from ten to more than two hundred fruit. Usually fewer than five fruit ripen daily on each plant during the three- to four-week fruiting season. The first night they are available, nearly all the ripe fruit are taken by bats.

At 2:00 in the afternoon, the sky quickly darkens and, accompanied by thunder and lightning, a brief but intense shower dumps a tenth of an inch of rain on the forest. Howler monkeys roar in protest but eventually become resigned to another soaking. White-faced and spider monkeys and many species of birds sit quietly under the partial protection of the leafy canopy and wait for the storm to pass on to the west.

Other than seeing a small trickle of water flow through the Duende cave, our female *Carollia* and her roost mates are unaffected by the afternoon precipitation. However, at other times in the rainy season, especially in late May or early June and again in September and October, heavy rains fall for several hours daily for a week or more. At these times, the Quebrada El Duende is a rushing river that completely floods the cave, causing the bats to seek shelter in nearby hollow trees or in rocky crevices downstream. Except for these relatively short interruptions, the cave remains a cool, dry refuge for the bats.

By 3:30 the storm has passed, and the bright, late afternoon sun begins to dry off the vegetation. As it sinks lower, the sun illuminates more and more of the coppery red trunks of one of the common trees in the dry forest, *el indio desnudo* (the naked Indian tree, *Bursera simarouba*), turning them into fiery pillars in a mosaic of glistening leaves. As the afternoon sunlight fades, daytime birds and mammals briefly increase their feeding activities before returning to their roost trees, vines, or dens for the night.

The Duende cave bats are restless by late in the day; at sunset, they start to leave. The first species to go is a half-ounce fruit and nectar eater, the long-tongued bat, *Glossophaga soricina*. At about 6:20 these delicate bats depart quickly and fly either singly or in small groups to search for an evening's meal. For most of the year, *G. soricina* bats eat a variety of fruit, including many of the same species consumed by *C. perspicillata*. In the dry season, however, *G. soricina* feeds on nectar and visits several night-blooming species, such as the legume shrub *Bauhinia ungulata*, and trees such as *Inga vera, Hymenea courbaril, Ceiba pentandra* (the commercial source of kapok), and *Bombacopsis quinata*.

The short-tailed fruit bats leave the cave between 6:30 and 7:00 P.M. By the time the female stretches her wings and makes a couple of warm-up flights around

A landing, a foothold, and a quick chomp, and the bat is off to savor a bite in the safety of a concealed night roost.
Richard LaVal

the inside of the cave, most of her harem mates have already left. At 6:45 she darts out the upstream end and turns north, flying through relatively open parts of the darkening forest at a speed of twelve miles per hour. In five minutes she reaches a small patch of *P. amalago* where she has fed for the past three nights.

Upon arriving at her first feeding area, she flies over the shrubs and quickly locates a ripe fruit by its slightly sweet smell. She grabs the fruit in her mouth while still in flight. It easily detaches from its thin branch, and she carries it to a dense bower of leafy vegetation—her night roost—about forty yards away. She will use this roost, chosen for the amount of cover it provides from predators, for as long as she visits this patch of plants. Hanging on a vine, she holds the fruit between her wrists and bites into the juicy pulp and small, bullet-shaped seeds, while rotating the fruit corn-on-the-cob style. In less than a minute and a half she has devoured most of the pulp and seeds from the fruit's central stem, which she now drops. Flying back to the patch, she picks another fruit and returns to her night roost to eat. After eating two more fruit this way, she stops to rest.

Now, having eaten four fruit, she's full and rests quietly, often sleeping, until her stomach empties. Fruit pulp and small seeds move rapidly through *C. perspicillata*'s relatively short digestive system, and she begins to excrete most of the seeds from her first fruit in twenty minutes. These seeds, as well as most of the others she has recently swallowed, will be deposited on the ground beneath her night roost.

Because the bat has used this same roost for several nights, hundreds of *Piper* seeds have fallen in a small area. This concentration of seeds will, within a day, attract the attention of several species of seed-eating animals, including harvester ants of the genus *Pheidole* and a spiny pocket mouse (*Liomys salvini*). The ants will carry many seeds to their nest and either eat them or store them for future use. The pocket mouse will eat many of the one-tenth-inch-long, spicy seeds immediately. Others it will place in its fur-lined cheek pouches and carry back to its burrow. As the mouse rummages through the leaf litter looking for more *Piper* seeds, it inevitably will push a few seeds into crevices in the soil where they can't be detected by seed predators.

Many of the plants producing fruit eaten by short-tailed bats are short-lived, early successional species whose seeds lie dormant in the soil until a disturbance—a tree fall, a forest fire, or the collapse of a stream bank—exposes the seeds to the levels of light required for germination. From a plant's point of view, *Carollia*'s major service is to distribute large numbers of seeds throughout the forest, thereby replenishing the soil seed bank. Seeds deposited in actual or incipient light gaps have the greatest probability of germinating and eventually providing food for new generations of frugivores.

While the bat is resting, her roost mates also feed or rest at various locations away from the roost. Two other females and a bachelor male, as well as several *G. soricina*, are feeding in this *P. amalago* patch. These bats often encounter each other as they search for fruit, but they do not fight or try to defend food patches. Mainly, they ignore one another and operate independently. Because the amount of fruit is limited, the bats do compete for it, but more by scrambling for access to it than by interfering with each other.

At this time of the year, food levels are high and most short-tailed fruit bats living in the Duende cave feed within a mile of the day roost. They go to a variety of areas north of the roost and others either east or south. In the dry season, when fruit is much more widely scattered, individuals must fly about twice as far from their roost, often far to the west and south, to find food.

Female and bachelor short-tailed males don't seem to have any particular social conventions about where they feed. However, females usually do not eat near their harem mates or their harem males. Bachelor males pay little attention to which bats are in the neighborhood when they're feeding. Only male bats with harems feed in predictable locations: because they often have to defend their roosting sites against other harem males or older bache-

lors at night, they usually stay within 500 yards of those sites. To get food, these males generally dart out of the cave, grab a fruit, and return with it to their territory. Most of the seeds they eat are excreted in the cave rather than in the forest.

After about an hour's rest, the female bat is ready to feed again. She returns to the same patch, but it takes her a bit longer to find two ripe fruit because of the other bats feeding there. After eating the two fruit, she rests briefly and then flies 220 yards east to another *P. amalago* patch she discovered two nights ago. She eats three more fruit here, then sleeps lightly for another hour. Again she excretes nearly all of the seeds she has recently ingested, including some seeds from her first feeding site, under this second night roost. So far this evening, she has done little to scatter the seeds she has consumed. Most have fallen on vegetation or on the ground within about 50 yards from their mother plants, but some have become intermingled with seeds from a different *P. amalago* patch. Over the years, bats move *P. amalago* seeds to many locations, sometimes miles away from their origin, and thus affect these patchily distributed plants by making their population's genetic structure more homogeneous.

After eating two fruit, the female bat moves again, this time about a mile southeast, to a *Cecropia peltata* tree growing along a creek bed. Prior to the ripening of *P. amalago* fruit, she fed almost exclusively at this tree for several weeks. Like plants in the genus *Piper*, *C. peltata* trees bear only a few ripe fruit each night, but they do so for several months, rather than several weeks. *C. peltata* fruit contain hundreds of small seeds and are much larger than *Piper* fruit. Rather than carrying off an entire fruit, a short-tailed fruit bat must land on the 2¾-inch-long *C. peltata* fruit, bite off a small chunk, and carry that to its night roost to eat. Just two or three entire *C. peltata* fruit could fulfill a bat's daily energy requirement of about nine kilocalories, compared with thirty-five to forty *Piper* fruit. But even so, the short-tailed fruit bat prefers the smaller fruit, probably because its pulp is richer in

protein, a critical nutrient for small frugivorous mammals, and because it contains less nondigestible plant fiber per unit measure.

The female bat makes two visits to the *C. peltata* tree from a new roost, which here is in the crown of a large *Pithecellobium saman* tree located thirty-five yards upstream, before resting forty minutes. She naps, and upon waking grooms herself briefly before departing for the *C. peltata* tree again. Her flight path takes her across the silver sliver of a late-rising moon, a movement that catches the attention of a mottled wood owl (*Ciccaba virgata*), perched twelve feet away from the fruit tree. Launching itself silently from its perch, the owl intercepts the bat five yards short of her goal. The bat dies instantly as the talons of the owl's right foot pierce and crush her chest. The owl, normally a hunter of small rodents such as the spiny pocket mouse, has chosen tonight to concentrate on bats flying into a fruiting tree. Its success rate has been good; it has killed two short-tailed fruit bats in four attempts.

By dawn the owl has regurgitated the skull and crushed limb bones of the female bat near its own sleeping roost deep in the forest. At the Duende cave, the bats, with one or two exceptions, have returned to their roosting places. Our female's only surviving offspring, a two-year-old female, lives in a small harem six feet from her mother's. She is pregnant and will give birth to a male in one month. If lucky, perhaps she too will live to be five years old. She will have to be constantly vigilant to survive that long, however, for bat predators are common in this habitat. In addition to various owls, these include snakes, arboreal opossums, and the largest New World bat, *Vampyrum spectrum.*

As the bats begin their thirteen-hour rest, the white-faced monkeys descend from their sleeping trees to feed on *C. peltata* fruit near the cave entrance, and a turquoise-browed motmot starts to issue its monotonous call from a low branch in the nearby forest. At Quebrada El Duende, the daily cycle has begun again. □

A frog-eating bat swoops in at the base of a large hollow tree, while a short-tailed fruit bat, probably on a fruit foray, enters the dense forest understory.

New Life on the Mississippi

The great river is building itself a new delta at the mouth of Louisiana's Atchafalaya River—its future path to the sea

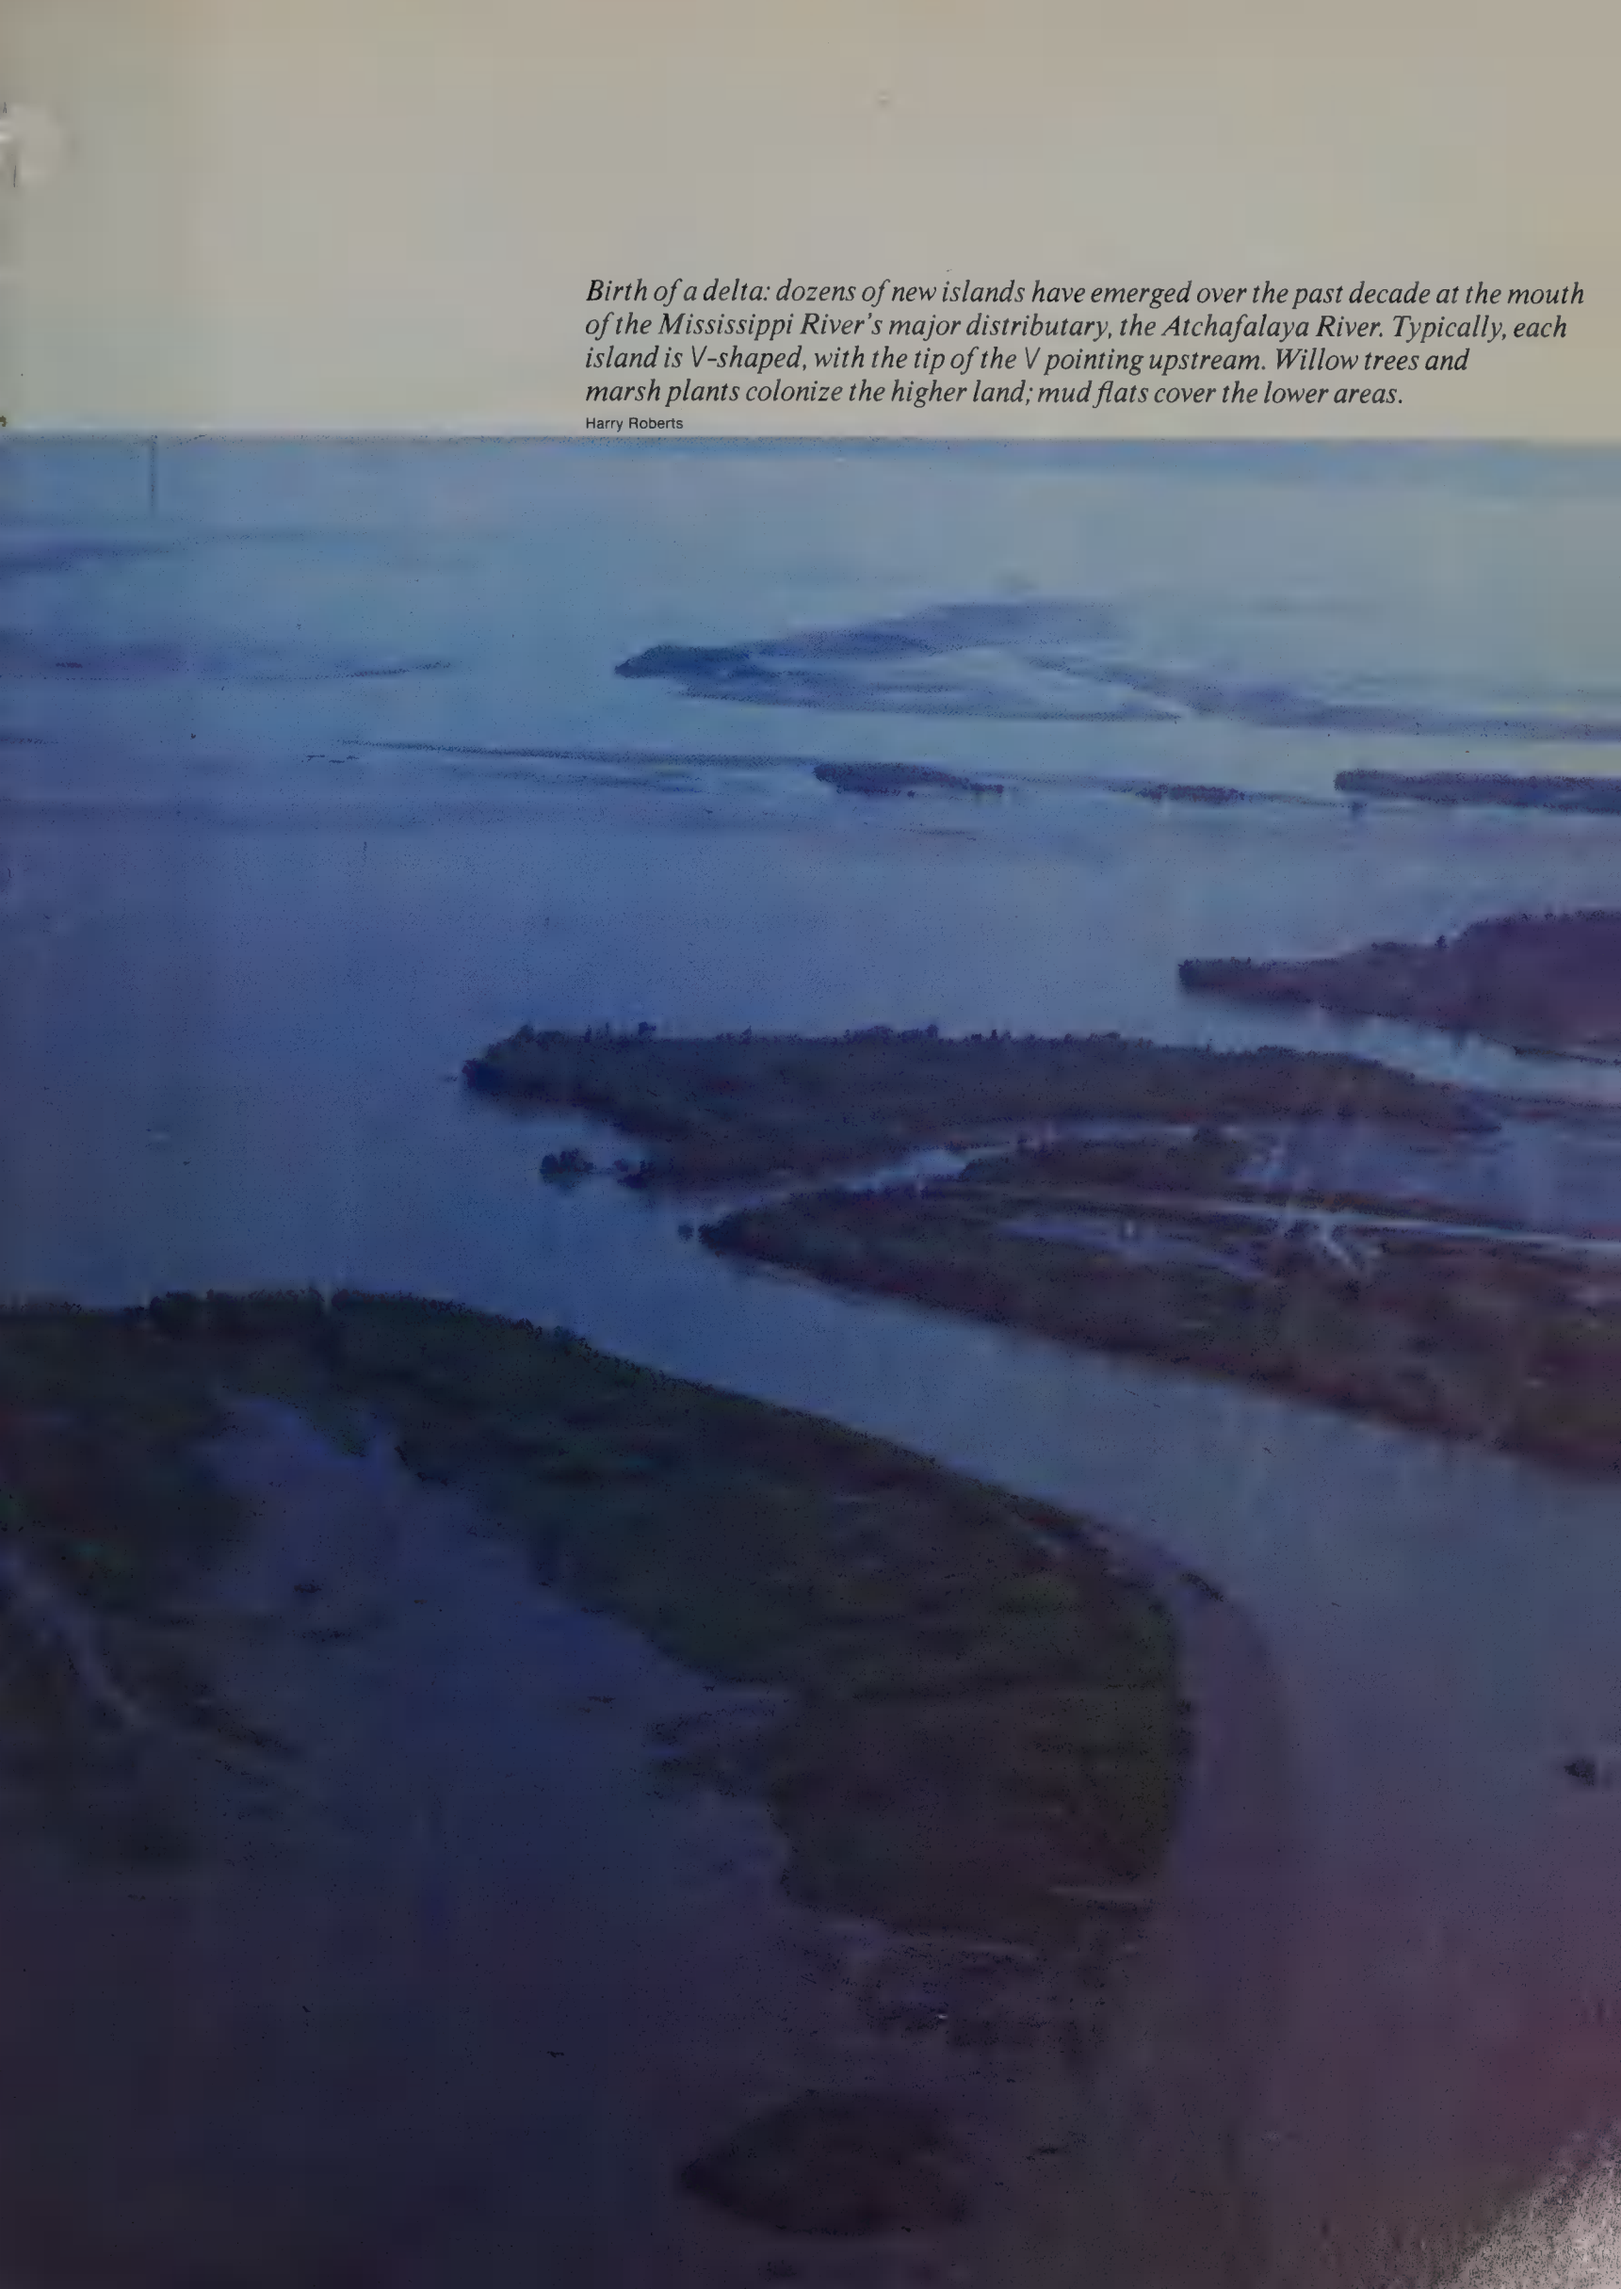
by Linda A. Deegan and Christopher Neill

As an early April morning fog begins to lift, we pilot our nineteen-foot Boston Whaler—with its three-person crew and cumbersome cargo of trawls, seines, ice chests, and countless empty bottles and jars—toward the edge of a marsh. In the middle of a channel we have successfully navigated for almost a year, the sudden low-pitched groan of the engine tells us we've hit mud. So we get on the push poles, trying to use the position of several willow-covered islands in the distance to guide us to deeper water.

Finding ourselves hard aground in a spot where we floated easily just one month ago comes as no real surprise to those of us studying one of nature's most dynamic ecological events—the emergence of a new river delta. And when the new delta is being built by one of America's major rivers, the Mississippi, every little change seems like big news. The new delta, and the Mississippi's inevitable new meeting place with the sea, lie 120 miles west of the current outlet and well west of the city of New Orleans, at the mouth of what is now the great river's most important distributary, the Atchafalaya River.

At least six times since the sea rose to its current level at the end of the last ice age, the Mississippi has shifted course, abandoning an aging, deteriorating delta and building a new one. All of coastal Louisiana was created in the process. Each delta was built out of the same material—topsoil imported from 2,000 miles upstream, where the Mississippi cuts through the American heartland. Hundreds of millions of tons of soil are picked up by the river and carried to the shallow coast of Louisiana each year. As any delta grows and matures, the river channel becomes choked with sediment and carries water less and less efficiently. The river's path becomes longer and more sinuous. In response to the back pressure on the system, the river starts shunting more of its flow down a distributary channel that branches off far upstream. The smaller channel carries the sediment that initiates formation of the new delta; eventually it captures the river's entire flow.

This is the fundamental mechanism by which the Mississippi's deltas have been



Birth of a delta: dozens of new islands have emerged over the past decade at the mouth of the Mississippi River's major distributary, the Atchafalaya River. Typically, each island is V-shaped, with the tip of the V pointing upstream. Willow trees and marsh plants colonize the higher land; mud flats cover the lower areas.

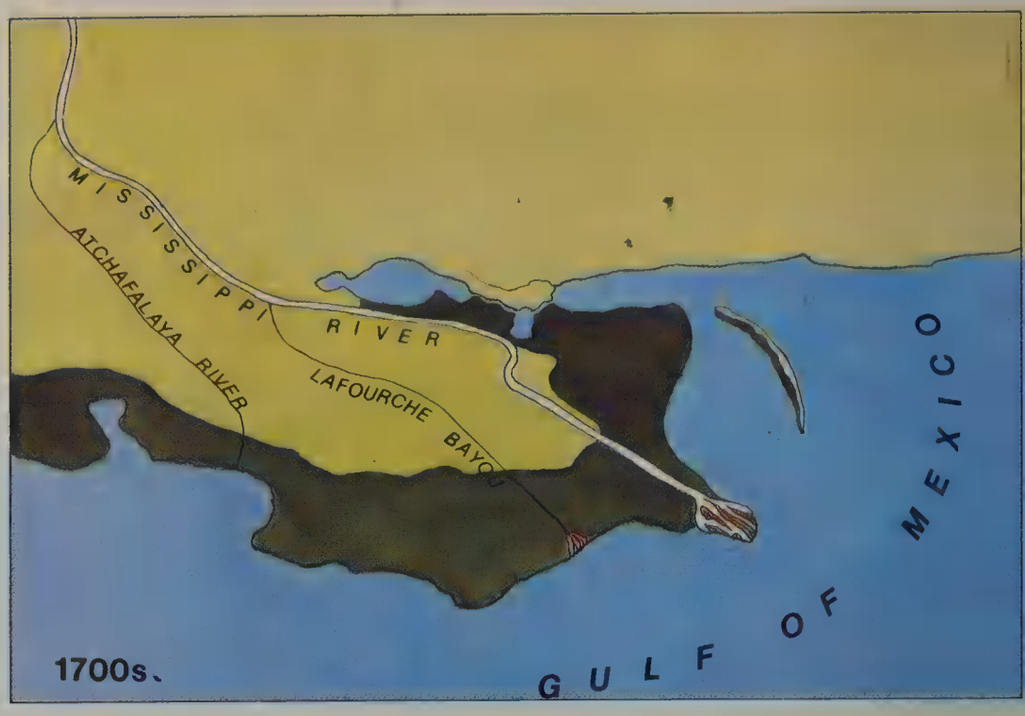
Harry Roberts

built. During the past two decades, a new delta has emerged at the mouth of the Atchafalaya (a Choctaw Indian word meaning long river, pronounced *A-cha-fuh-lie'-yuh*). It is the newest in a chain of Mississippi River deltas with historic and colorful names, like Maringouin (6,200 to 7,200 years ago) and Teche (3,900 to 5,700 years ago), the more recent Lafourche (60 to 3,500 years ago), and the current Plaquemines-Balize (1,000 years ago to present).

The Atchafalaya River was a distributary of the Mississippi as far back as the 1500s. During the middle and late nineteenth century, logjams at the junction between the rivers and continual dredging of the Mississippi's navigation channel prevented the big river from flowing freely into the offshoot. In 1839 the logjams were cleared to aid navigation, and a new phase began in the formation of the delta. More and more water flowed into the Atchafalaya; now the branch river is threatening to take over the last leg of the Mississippi's trip to the Gulf of Mexico.

It certainly would be a straighter run. From its junction with the Mississippi 45 miles northwest of Baton Rouge, the Atchafalaya sprints 140 miles, most of them straight south, to the coast. The Mississippi itself lumbers along another 330 miles from that same junction before spilling into the Gulf. The Atchafalaya has the laws of physics on its side. By the early 1940s, researchers were predicting that, without human intervention, the Mississippi would change course by 1975. But the U.S. Army Corps of Engineers did intervene. In the 1940s and 1950s army engineers built levees to contain the Atchafalaya; in 1963, they added a dam known as the Old River Control Structure. Now, no more than 30 percent of the Mississippi's waters are allowed down the Atchafalaya at any given time.

Still, a lot of ecological work is being done. Millions of tons of new sediment are delivered to the Atchafalaya delta each year. On its way, this underwater cargo clogs shipping channels and creates a headache for the Army Corps of Engineers. But this is the stuff that turns an open bay into a river delta, and changes at



Diane Baker

The Mississippi River's current Plaquemines-Balize delta, top left, was expanding (red) in the eighteenth century. By the late nineteenth, more water and sediment were going down the Atchafalaya. For years, the sediment was trapped inland in lakes and bayous. By 1950, middle left, most of those water bodies had filled in (green) and some particles began to be carried into Atchafalaya Bay. These laid the groundwork for the new delta. The first islands, bottom left, appeared with the 1973 spring flood; more have emerged since then. During the same period, the Plaquemines delta eroded. Olive green areas are coastal marshes. Below: A Cajun lumberjack camp along the Atchafalaya River, in 1880. Many Cajuns live off the land in the Atchafalaya basin today.

Special Collections Division; Howard Tilton Memorial Library; Tulane University

the mouth of the Atchafalaya have been startlingly rapid.

As we steer our boat from the mouth of the Atchafalaya into the bay, the landscape opens up and all we see is sky and water; the horizon is broken only by the outline of small, tree-covered islands. These are the closest things a delta has to terra firma. As a group, the islands are spread in the shape of a tree, but this is only visible from above. From a motorboat, the area seems small, almost unremarkable (the islands cover only about 5 percent of the bay), but there is more to a delta than what appears on the surface. In most places, the water is only six inches deep. Below that are shoals, sediment-filled areas that are not yet land but no longer belong exclusively to the sea. These shallows are the trademark of any delta.

If we tie up at one of the bigger islands and hike to the tangled willow trees that usually grow at the highest point, we can see marshes. They start below the willows and extend several hundred yards. The marshes lie at a lower elevation than the willow-covered headland, and they exist in the nether world created by the changing water levels. The plants are adapted to the constant rise and fall of river water and can survive for long periods with just their leaves above the surface.

Beyond the marshes are the mud flats. Like the marshes, they are flooded at high water and uncovered at low, and they extend out into the distance as far as we can see. An island's mud flats are easily ten times the size of the island itself. Anybody who walks from the willowed island head through the marsh and out onto the back flats is asking for a mud bath—in some places up to the waist. It is a difficult place for humans to move around in. We have often wished there were special skis that would let us skim over the slick surface, but no matter what we rig up, we still sink with every step. Although a mud flat is under water most of the time, we can judge its size by looking for the protruding skeletons of trees. Huge ones are washed down the river every spring, and wherever we see these ungainly markers, we know there are flats beneath them.

Although they seem barren, mud flats are extremely productive habitats. Under the thin sheet of water is a film of tiny plants—golden diatoms and green filamentous algae. The flats are cut by an intricate network of bifurcating channels that carry nutrient-rich waters to a host of small animals that live in the soft mud. Taken together, these mud flats, along with the marshy, willowy islands, cover about thirty square miles. These, for now, are the limits of the new delta.

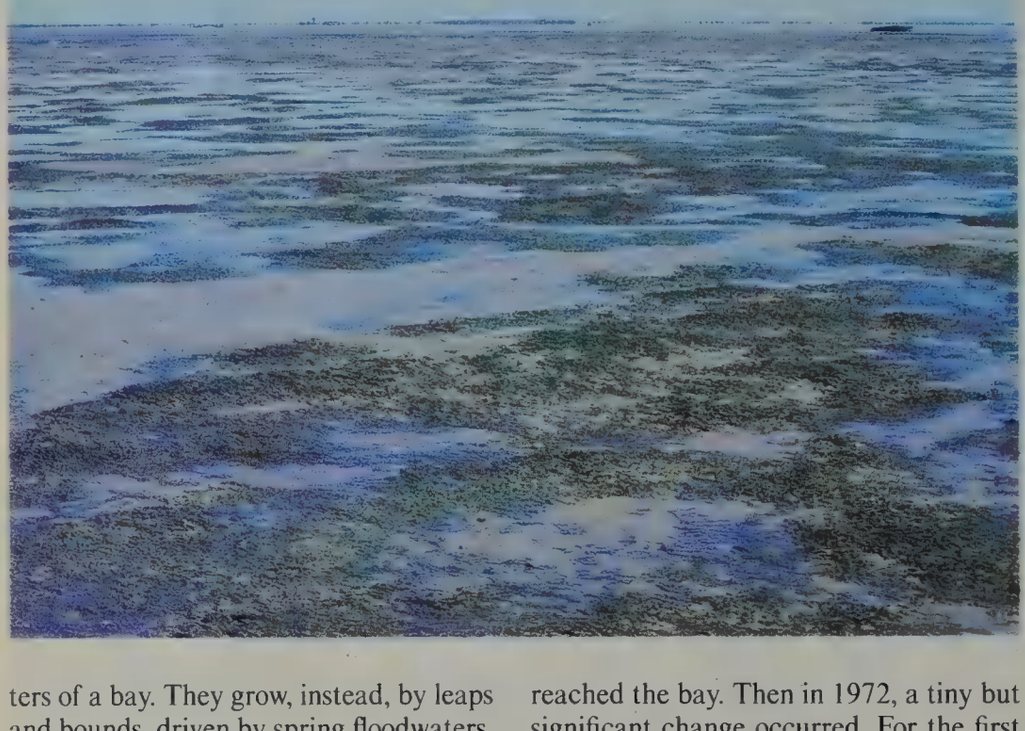
Scientists from the Center for Wetland Resources at Louisiana State University have been studying the delta since its inception in the 1950s. We joined this research team five years ago, and much of what we have learned has depended on the work of many others.

One thing we learned pretty quickly was that deltas do not march in a steady and regular fashion into the shallow wa-

Dan Guravich

An island's mud flats, below, are prime feeding grounds for birds and fish in the Atchafalaya delta. The mud is full of worms, and tiny plants cover the surface. The material that built the mud flats is sediment delivered by the Mississippi into the Atchafalaya at the junction of the two rivers, right. The dam known as Old River Control Structure (center) limits the amount of water flowing from the Mississippi into the Atchafalaya, preventing the big river from changing course.

Ron Paille



ters of a bay. They grow, instead, by leaps and bounds, driven by spring floodwaters. The first sediment showed up in Atchafalaya Bay in the 1950s. But for half a century before that, floods had laid the groundwork. During those years, the silts and sands that spilled out of the Mississippi into the Atchafalaya were trapped in the Atchafalaya's inland flood plain basin—essentially a giant swamp laced with lakes and bayous. Only after most of these water bodies had filled with sediment did large amounts of material flow south into the bay.

The first arrivals were very fine-grained clay particles, which are light and easily transported. At first most of them overshot the bay and ended up in the Gulf of Mexico. There they drifted west and piled up along the Louisiana coast, forming gooey mud flats up to six feet thick.

The specks of clay and slightly heavier silt that did settle out in Atchafalaya Bay began to accumulate and to form a broad, flat underwater shelf, called a prodelta platform. The process fed itself—the more the sediment piled up, the shallower the bay became, and then even more sediment could be trapped. This pattern continued for twenty years. With each spring flood came a new load of sediment, which skimmed over the inland sinks and reached the bay. Then in 1972, a tiny but significant change occurred. For the first time, sands—much heavier than silts and clays—slipped past the flood basin. With these particles in the mix a new phase of delta development began.

It could have taken years, but instead it happened the next spring. In 1973, a great flood swept through Atchafalaya Bay, affecting waters as far as fifteen miles offshore and forty miles to the west. The Atchafalaya River hit a peak, carrying five times its average volume. When these rushing, silt-filled waters reached the bay, they slowed down and a number of intriguing things began to happen.

First, some of the river became part of the bay. It happened when sediment fell on either side of the river's main channel, forming natural underwater banks. Simultaneously, the river dropped sediment onto its own mouth, which piled up in its path and created a shoal. Because of the particularly important location of the shoal, it's called a distributary mouth bar. More and more sediment piled on; the bar grew in height and width, and before long the obstruction broke the surface and caused the river to split. Now there were two channels, but soon there were four, as new bars bisected the channels again. When the 1973 flood was over and the floodwaters moved on into the gulf, they left behind the beginnings of the new delta—with its present configuration of islands (distributary mouth bars) and channels but no vegetation. These were the first delta islands.

The flood of 1973 was followed by others in 1974 and 1975. These were not as big as their predecessor but they piled more mud on the newly formed mud flats and channel banks. Over this three-year period, 183 million cubic yards of sediment was deposited in the delta—enough to bury the entire state of Connecticut under a half-inch of glop. Floods in 1979 and 1983 added even more. Each of these floods enlarged the original islands and added new ones. Now there are sixty-two of them, ranging from a few square feet to twenty acres.

There is a characteristic shape to all of

the islands. It is a V, whose tip points upstream. The arms of the V are the banks of the new channels on either side. The tip and arms are the highest points because, facing upstream, they receive the greatest supply of sediment. The lower interior trails off into the mud flats.

Since new delta islands are virgin land totally devoid of vegetation, they offer an unusual opportunity to study primary plant succession. To colonize new delta land, plants must be opportunistic species, adapted to changing environments. Their seeds must be able to travel far and grow quickly. Then, once they've gained a foothold, they have to be able to tolerate frequent flooding and a continuous barrage of new dirt.

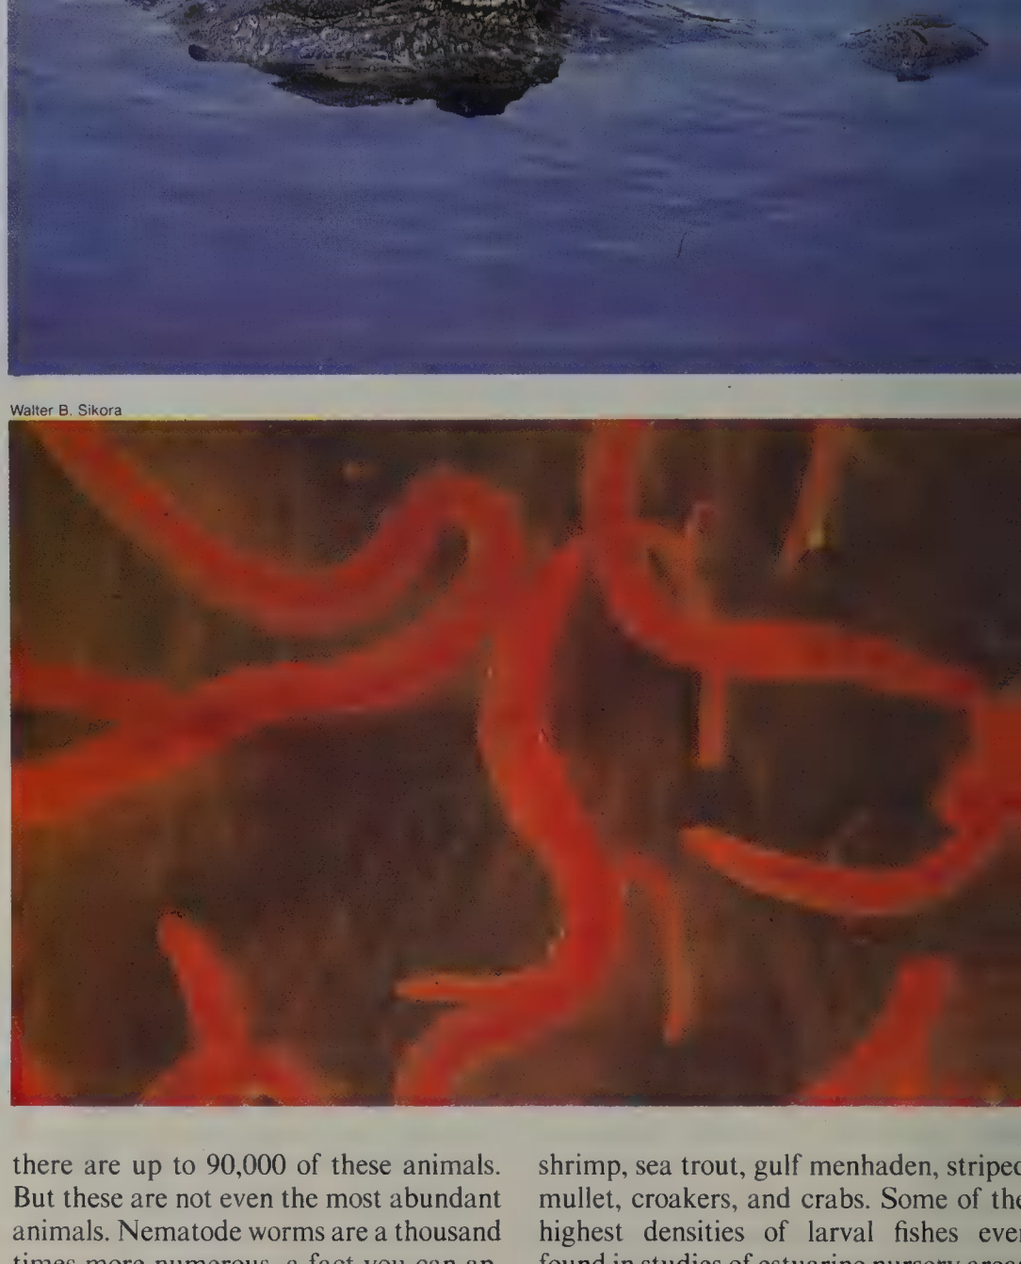
Arrowheads, several species of fleshy, broad-leaved marsh plants, have not only coped with these problems; they seem to thrive on them. They have pioneered every new island in the Atchafalaya delta. Able to establish themselves in one season, arrowheads are superbly adapted for colonizing. Their flat seeds float downstream on the river. As soon as they hit land, their membranous wings help stabilize their position in the soil. There are other resourceful marsh plants, like rushes and sedges, but arrowheads are unique because they produce underground tubers. At the end of the first growing season, the top part of the plant dies back for the winter, and energy—in the form of starch—is stored in the tuber. This strategy allows the plant to sit out the worst rages of the spring flood and then, when the water level drops back to normal, to draw on reserves and grow.

Arrowheads take the high ground first, colonizing the upstream edge of the islands, which can be as much as a foot above average water level. Elevation is crucial here, for even a couple of inches alters the amount of time plants stay submerged; and when a plant is being pushed to its physiological limits, a few extra hours underwater can kill it. Inches also determine species distribution. Broad-leaved arrowhead thrives on slightly raised portions of the islands; but delta duck potato, its close relative, can grow almost completely underwater and occupies lower portions of the mud flats.

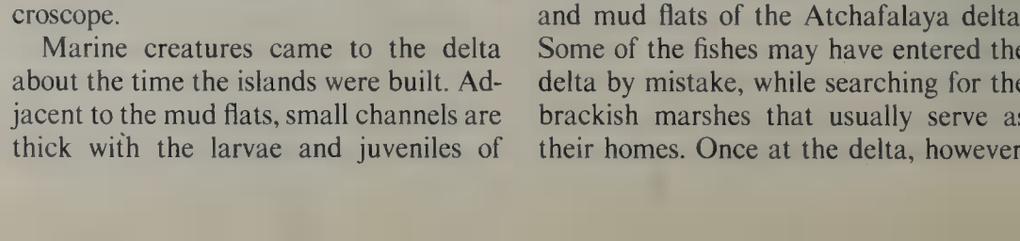
The growth of vegetation after the 1973 flood followed a pattern that seemed curious at first. No plants at all sprouted the first year. By the end of 1974, however, vegetation covered 219 acres. By 1975, after yet another flood, 380 acres had been colonized by plant life. But the most surprising change came the following year. Little new sediment had been deposited

Alligators, below, are predators at the new delta; they go after fish and, sometimes, birds. Other important prey are nutria, facing page, slow-moving, semiaquatic rodents whose thick fur is sometimes sold as "simulated" mink. Herbivorous, nutria live in marsh areas on the delta islands. Oligochaete worms, bottom, live in mud flats and are usually concentrated in the top inch of mud. Both birds and fish feed on them.

Dan Guravich



Walter B. Sikora



during the spring flood of 1976, but when scientists surveyed the vegetation later that year, they found the delta's colonized area had more than tripled, to 1,117 acres. What we have come to understand is that low flood years actually encourage plant growth. Plants are submerged in the cold, turbid water for a shorter period, and as a result they get more light and the soils stay warmer. Ultimately, high and low floods work together: highs bring the land and seeds, lows encourage plant growth.

Arrowheads are the original settlers, but when the river adds another foot or two to an island, black willow trees appear. Black willows are the best tree colonizers of wet, low-lying areas. Their silky-haired seeds come by wind to the delta, and they come by the millions. When willow seeds fall onto a suitable spot for germination—much too wet for most other trees—they grow like crazy, producing a twisted tangle of trunks that is difficult to penetrate. Most important, willows stabilize the ground they sit on, trapping new sediment and using their tough stems to protect the marshes from river currents.

Until now, the river itself has controlled island development by determining elevations and sedimentation. But once willows are established, the river's power is more limited. Plants now have an influence. An array of them follow the willow in—towering cattails, roseau cane, softstem bulrushes and spike rushes, alligator weed, among others. Annual flowering plants such as goldenrod and asters take hold on the highest and driest ground. Eventually, the marsh on the downstream side of the island gains a measure of independence from the river.

But not all the residents of the delta are immigrant plants. One of the unique characteristics of the new land mass is that saltwater and freshwater organisms seem to be able to coexist there. Some of the most prominent, but least visible, marine inhabitants are in the mud. Polychaete and oligochaete worms—the aquatic equivalents of earthworms—snails, tube-building crustaceans, and the larvae of midges all live in the mud. Many of these are concentrated near the surface. In a square yard of mud flat one inch thick there are up to 90,000 of these animals. But these are not even the most abundant animals. Nematode worms are a thousand times more numerous, a fact you can appreciate by examining the mud with a microscope.

Marine creatures came to the delta about the time the islands were built. Adjacent to the mud flats, small channels are thick with the larvae and juveniles of shrimp, sea trout, gulf menhaden, striped mullet, croakers, and crabs. Some of the highest densities of larval fishes ever found in studies of estuarine nursery areas come from the quiet, protected back coves and mud flats of the Atchafalaya delta. Some of the fishes may have entered the delta by mistake, while searching for the brackish marshes that usually serve as their homes. Once at the delta, however

Lloyd Poissenot

they found no need to move on. The adjacent mud flats are a storehouse of food, and the channels between them are warm and too shallow for fish predators.

Other species, such as freshwater minnows and sunfish, were carried in by the floods. While most were flushed out to the gulf and probably perished, the lucky ones found a current that ended in a shallow cove. There they have remained, becoming part of the unlikely assemblage of freshwater and marine fishes that thrives in the delta.

Worms, roots, tubers, fish, crustaceans—this has to be some sort of island paradise for bigger animals, if they can find a way there. The most obvious animals in the area are birds. More than a hundred thousand ducks may be found at the delta on any given winter day. They are lured in by the land formations and food. The ducks here are primarily dabblers—mallards, blue- and green-winged teals, gadwalls, pintails, and widgeons—which find the shallow waters good for feeding. These ducks are primarily vegetarians in the winter and forage on arrowhead roots and rhizomes. They also eat other aquatic plants, and sometimes insects, fish, and mollusks.

Wading birds have relocated to the delta. Great blue herons are a rather common sight. We often see them patiently stalking fish in the shallow marshes. And in the evening, if we sit by one of the willow island rookeries, we can watch flocks of white and white-faced ibis returning from a day's foraging on the mud flats. Strung out in silent lines, they float by and then drop, one by one, onto the island. Other birds you see on the delta: tricolored and little blue herons, snowy and great egrets, roseate spoonbills, which hunt on the mud flats during the day and return to the islands at night to feed their young, and black-crowned and yellow-crowned night herons. The number of birds has increased dramatically in recent years. As late as 1978, no nests of wading birds had yet been reported. Now we guess there are 20,000 nests of wading birds.

Shore birds also stop in at the delta during their annual migrations—by the thousands. Dunlins and other small sandpipers are common. Dowitchers, with their long bills, probe the mud for food. Avocets sweep shallow pools of water with their long upturned bills, and plovers run across the mud, plucking organisms from the surface. These birds usually stay from October to March or April. Because the arrowheads have died back, exposing the marsh surface, invertebrate food is now more accessible.

With all these birds in residence, one might expect some interesting mammals, but there are few of them at the delta. We wonder about this every time we cut off the engine of our boat and glide into the muddy edge of a marsh. The island sings us a ravenous song of welcome—the disturbed buzz of billions of mosquitoes. We can wrap ourselves in plastic rain suits, but other mammals don't have such armor. Most likely, however, the treacherous swim to the delta islands, rather than the bugs, keeps them away. The only mammal here in any numbers is the nutria, a slow rodent that resembles a giant muskrat. Nutrias were accidentally introduced into southern Louisiana in 1938 and have spread into every aquatic habitat. We don't know when the first nutria came to the Atchafalaya marshes, but there are enough of them now to support a trapper. He and his wife live on a floating house barge during the winter and leave the area once the warm weather comes. Nutria fur is often sold as "simulated" mink.

Recognizing that the place taking shape at the end of the Atchafalaya River was unusual, the state of Louisiana in 1976 declared the delta and surrounding bay to be a special wildlife management area. But that may not be enough to protect it against the interfering hand of civilization.

Startled teals launch themselves from a shallow marsh on a delta island. Birds, especially ducks, are the most visible wildlife on the delta. The ducks eat the tubers of one of the first plants to take hold on the delta, the arrowhead. The willow- and arrowhead-covered upstream end of the island is in the background.

C.C. Lockwood

Roseate spoonbills are not very common in Louisiana, except in three or four places, including the Atchafalaya delta. They may have been drawn there by the abundant food supply and absence of predators. The number of spoonbill nests has expanded in recent years. Since 1973, when the first delta islands appeared, the number of wading bird nests has grown to 20,000.

Dan Guravich

The abundance of life seems reason enough to be concerned about it. But some people are watching the area for other reasons. They know that what is growing there is part of a long cycle of upstream river diversion and delta building by the Mississippi River and that the Mississippi is ready to begin a new phase in that cycle. But they are apprehensive about a river switch because nature's plan threatens many people living in south Louisiana.

If the Old River Control Structure were to fail during a flood, and the Mississippi changed course, the result could be disastrous. Floodwaters would leave about 140,000 people homeless in Morgan City and surrounding towns in the Atchafalaya's inland flood plain. Bridges, highways, power lines, and oil and gas pipelines would be destroyed, wreaking havoc in Louisiana and interrupting the flow of oil and gas to northern states.

Even if the course change didn't happen so violently, it would still have serious long-term consequences. When the Atchafalaya captures the flow of the river, Baton Rouge and New Orleans will lose their freshwater supply, now brought in by the Mississippi. A million and a half people, along with the multibillion-dollar petrochemical industry that lines the banks of the river, would be affected.

But the cost of maintaining the river in its present channel is also high. All the levees that have penned in the Mississippi, holding it on course, prevent the river from delivering sediment to the coastal marshes. The present Mississippi River delta and much of coastal Louisiana are experiencing the highest land loss in the United States, about fifty square miles of marsh each year. Should the trend continue, Louisiana within twenty-five years would lose an area equal to the state of Rhode Island. Furthermore, the levees force the river to grow straight out into the Gulf of Mexico, dumping its sediment into water 120 feet deep. Most of it is wasted at that depth; it would take years for any new land to be built.

As the eastern side of the Louisiana coast is disintegrating, new land is being built to the west. Even though the Atchafalaya carries only a third of the Mississippi's sediment, the effects go far beyond the small amount of land created in the bay. Beyond the delta, but still near the mouth of the river, sedimentation is reversing a century-old trend of marsh loss. The Atchafalaya delta only absorbs about two-thirds of the mud it receives. The rest is mainly carried west by prevailing currents. And currently that mud is rebuilding an area along the western Louisiana

Willow trees cover a small island along the Atchafalaya River. Colonizers of wet areas, willows are prominent in the delta; their seeds are borne by wind.
C.C. Lockwood

coast called Chenier Plain, which until now has been one of the most rapidly retreating coastlines in the United States. But these long-lasting gains are often ignored in the clamor over the economic disruption that would be caused by a change in the Mississippi's course.

The battle between the Mississippi River and the Army Corps of Engineers continues, but nobody knows how long the humans can hold on. The official position of the corps is that the Mississippi can be contained indefinitely. Together with the Cajuns of south Louisiana, we are betting on the river. The flood of 1973 severely tested the Old River Control Structure and washed out one wing wall. To prevent the dam from collapsing, the corps had to dump thousands of tons of rubble into the hole dug by the river. Although construction of an ancillary control structure is nearing completion, ultimately, nature will have its way.

The Atchafalaya delta is different from the current Mississippi delta. For one thing, it is built in a shallow bay. Since less sediment is needed to build land in the shallow water, the Atchafalaya delta will grow more rapidly and eventually cover a wider area than the current Mississippi delta. In as little as a decade or perhaps up to a century, the series of separate islands now visible will merge together to form a broad expanse of fresh and brackish marsh, interwoven with shallow creeks and ponds. Clays and silts carried by the river will create another broad prodelta platform, like the one laid down before 1973. Another flood will trigger a new round of island growth and the fingers of the delta will reach farther, beyond the shell reefs that now form the seaward edge of Atchafalaya Bay.

The result of all this? A new coastline, with thousands of square miles of new land. It will be a spectacular land-building event, an incredible piece of work by an incredible river. But the Mississippi River has been doing this for thousands of years now, even in this same spot. For beneath the Atchafalaya delta are the remains of the Maringouin delta. This delta, as far as we know, was the great river's first delta, built more than 6,000 years ago. □

A Shattering of Stereotypes

by Sarah Blaffer Hrdy

FEMALE STRATEGIES, by Evelyn Shaw and Joan Darling, *Walker and Company, $14.95; 164 pp.*

Just about every woman biologist I know, either in amusement or in outrage, can rattle off her selection of "jacana tales." What? A jacana tale. One arises each time a researcher jumps to a wrong conclusion by assuming ahead of time how a male or female animal ought to be behaving.

Studies of the long-legged, lily-trotting birds known as jacanas provide classic examples of how sex stereotypes can cause us to misconstrue the natural world. For the jacana, like numerous other creatures, is what is known as a sex-reversed species (as though there were such a thing as sex normal). Male jacanas are smaller, more nurturing, and less aggressive than the females. The spindly little male dutifully cares for eggs deposited in his nest by females that travel between male nests, mating with as many males as they can manage, and fighting with other female jacanas for that privilege. Occasionally, female jacanas even destroy the eggs of competing females to gain more male attention for their own chicks. A fairly accurate accounting of jacanas has been on record for years, yet every so often one encounters in the pages of this or that scientific journal a vivid passage detailing the nest-tending antics of the female jacana, known to be the female, of course, because "Hey, look, she's the little one next to the nest!"

Evelyn Shaw, an eminent biologist known for her elegant studies of schooling fish and her many years as a dedicated teacher at Stanford University, has obviously encountered her share of jacana tales. Perhaps just one too many. For now, together with co-worker Joan Darling, she has written a book to set the record straight. *Female Strategies* reviews and celebrates the extraordinary diversity of a protean sex. Its primary goal, however, is "the shattering of stereotypes." "True," the authors concede, "females make eggs and males make sperm—for after all, that is how the two sexes are defined—but beyond this difference there are no universal axioms."

The shattering commences with Shaw's own specialty, small silvery perch that inhabit shallow waters along the Pacific Coast of North America. These are the shiner perch, which have turned out to be more promiscuous and far odder in their sexual habits than anyone could have dreamed possible. Even when her reproductive hormones are in low gear, with no ovulation going on, the female shiner perch is anything but sexually uninterested. Instead, she assertively courts and mates with as many males as she can with an abandon that, at first glance, appears to be sheer licentiousness, since she is in no condition to use the sperm. In fact, the female is stashing sperm in her ovaries, where they are stored, fed, and kept viable until she revs up endocrinologically for fresh egg production and in-house fertilization.

How are we to explain the behavior of this fish? First of all, we need to understand, as Shaw and Darling note wryly, that species such as these have not had the benefit of textbooks describing females as sexually "coy" and discriminating—textbooks that traditionally reserve the designation "promiscuous" for the male sex alone. Shaw and Darling suggest that the female shiner perch is taking out a form of

Don't Buy a Big Tiller

For a Small Job!

If your garden is an acre or more, you may want to buy a big tiller. If it's any less, you should buy a Mantis-20 (and hire somebody to plow or till your garden *once a year).*

Big tillers till and weed 20" (or more) wide. The Mantis tills and weeds a practical 6" to 9" wide.

Big tillers weigh almost 300 lbs. The Mantis weighs just 20 lbs! Simply turning a 300-pound tiller in a backyard garden without running over crops (or yourself) is a challenge.

Most big tillers were designed to just till (but many now offer clumsy "add-on" attachments to try to justify their high cost). The Mantis-20 was *designed from the beginning* to precisely match a small, powerful engine to a variety of useful attachments for your yard and garden. Tiller. Cultivator. Furrower. Edger. Lawn Aerator. Lawn De-Thatcher. Hedge Trimmer.

Most big tillers cost an arm and a leg. Despite the fact that the Mantis-20 is a tough, durable, precision instrument . . . it costs a *fraction* of what you'll pay for a big tiller.

Finally, look at the warranty. Most machines are *partially* covered for 90 days to a year. The Mantis has a *Lifetime Warranty* on the tines (if they *ever* break, we'll replace them). A *Lifetime Replacement* agreement on the engine. And, best of all, a *3-Week In-Your-Garden Trial* (if you don't like it, we'll take it back and give you a full refund)! The unique Mantis Promise is unmatched in the industry. If we didn't make such a fine machine . . . we couldn't make such a fine offer.

- Easily weeds an average garden in 20 minutes
- Women and older gardeners love Mantis because it weighs just 20 pounds, turns on a dime, starts with the flick of a wrist and does so many jobs for them
- EARLY ORDER BONUS (if you hurry)
- Tines *guaranteed* forever
- A 3-Week IN-YOUR-GARDEN TRIAL (that won't start until *you* start gardening)

What a pleasure to use. Never again will we have to rent a tiller, work like crazy to get it back on time, need two people to put it into and out of the car, get bounced all over and wind up with sore arms and headaches.

Ruth and Patrick Eagen
Hempstead, New York

The Word Eraser! The Eraser!

Introducing WordEraser for mistake-proof typing by Smith-Corona.

The word is out! Smith-Corona has just revolutionized erasing. With one button. The incredible WordEraser™ correction. It untypes whole words at a touch.

No skip ping. No c-o-u-n-t-i-n-g. N oovershooting. And that's not all. The WordEraser even lets you type in your new word while it untypes the old one. Amazing is the word for it. And only Smith-Corona has it.

The WordEraser. Another of the many technological advancements pioneered by Smith-Corona. Make no mistake about it.

SMITH CORONA™

:netic insurance. By storing the sperm, e female has control over timing, and ith sperm from several fathers in tow, ıe has a backup should some gametes fail survive their ovarian interlude.

There are many possible reasons that males solicit multiple partners, but hatever the reason, all sorts of fish, sala-ıanders, butterflies, and garter snakes, as ell as most primates, turn out to be less ıan chaste. It has only been in the last :w years, with books such as this one (as ell as Meredith Small's *Female Pri-ıates* and Samuel K. Wasser's *The So-ial Behavior of Female Vertebrates*), ıat this sexually assertive facet of "femi-ine nature"—every bit as real as the ıuch mentioned "choosiness" of fe-ıales—is beginning to be discussed.

Female Strategies provides a fascinat-ıg sampler of what Shaw and Darling :rm the "liberated ladies of the animal ingdom." For starters, they turn to the :ores of invertebrates, fishes, and am-hibians that possess at birth the potential ɔ become either sex or even, in some ases, to be first one sex, then switch to the ther.

Consider the slipper shell, "a common eashore snail with the provocative name f *Crepidula fornicata*, so named because ıore than a dozen snails stacked on top of ach other live in permanent polygamous ınion. The big one on the bottom is always he female, and a male becomes a female vhen another slipper shell lands on top of t." Becoming a female, then, is purely a ɔositional matter. For the grouper fish, exual identity is even more slippery. Af-er shedding her eggs, this hermaphroditic ıum switches from the female to the ıale role and begins to spray sperm.

Shaw and Darling routinely combine ɔoetry with marine biology to carry us into he world beneath the sea. Into the depths ve dive, accompanying our authors as un-lerwater midwives to a female squid: 'There in the newly dark dusk and the irst glimmers of dawn, the female adver-ises her readiness to mate by projecting ıer squidy musks and exhibiting a coral-colored shell gland, easily seen through ıer translucent skin." She is attracted by 'ropy masses of squid eggs entwined with he algae on the sea floor," the sight of vhich serves as a massive aphrodisiac for ɔoth sexes. "The newly receptive female ıllows any nearby male to hug her in a ıany armed embrace." Thus held, she is ınseminated and released, not to lay strings of eggs, but to interweave them in a vast tapestry of eggs left by hundreds of ɔther mother squids, covering an area as arge as forty square feet. The resultant mass is so large and so complex that no

Better than Jogging, Swimming, or Cycling...

NordicTrack

Jarless Total Body

Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Cross-country skiing is often cited by physiologists as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles so higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the pleasant X-C skiing motion and provides the same cardiovascular endurance-building benefits–right in the convenience of your home, year 'round. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

More Complete Than Running

NordicTrack gives you a more complete work out–conditions both upper body and lower body muscles at the same time. Fluid, jarless motion does not cause joint or back problems.

More Effective Than Exercise Bikes

NordicTrack's stand-up skiing motion more uniformly exercises the large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass.

Even Better Than Swimming

NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. When swimming, the body is supported by the water, thus preventing these muscles from being effectively exercised. The stand up exercising position on the NordicTrack much more effectively exercises these muscles.

A Proven, High Quality Durable Product

NordicTrack is in its 7th year of production. NordicTrack is quiet, motorless and has separately adjustable arm and leg resistances. We manufacture and sell direct. Two year warrantee, 30 day trial period with return privilege.

Folds and stands on end to require only 15" x 17" storage space.

predator can swallow it or even tear eggs free, and "the sea's currents would have a hard time uprooting this vast tumbleweed of the squid's next generation."

Such prose is the great success of this book, and I am in complete accord with the authors' main proposition that when we use the adjective *female* in its widest sense, we would do well to take nothing for granted. The stereotypes Shaw and Darling assault are all too real in the literature of evolutionary biology (though the detection of these stereotypes is perhaps not so recent nor so revolutionary with this book as the authors imply). The actual variety found in this most protean sex will exceed our wildest imaginings.

But there are undercurrents to this book that I find disturbing. As species after species is described, a new kind of double standard emerges, one for humans, for whom almost anything is possible, and another for nonhuman species, whose reproductive lives are governed by strict rules. Even the creature that changes sex does so in a totally predictable manner. "The females of every species but one live lives whose reproductive strategies are predetermined." I would argue, however, that the extraordinary degree to which reproductive strategies are situation-dependent has been greatly underestimated, especially for primates but also for other creatures. Even among some birds, such as dunnocks or acorn woodpeckers, and certainly among primates, such as the little mongoose lemur, one finds females that are monogamous in one context and polygamous in another. Some South American tamarins may be nonbreeding at one time and either monogamous or polyandrous at another, depending among other things, on ecological and historical circumstances. At the same time the notion that human possibilities are infinite strikes me as ideologically admirable but overly optimistic. And the authors do not really address such difficult questions as how biology affects and interacts with social construction of gender. Surely culture is not the only thing that separates a woman from a shiner perch?

Shaw and Darling celebrate the nearly infinite variety of species, venturing the hopeful speculation that "with a new understanding of the biological basis of femininity, can new cultural forms of femininity be far behind?" Such a passage merely underscores the point that the authors have really not given much thought to what nature's diversity actually means for women. Surely they are not suggesting that we take "nature's liberated ladies" as our templates? Just to carry this argument to an absurd extreme, consider the shine

erch. By the standards that most femi-
ists hold dear, this fish's behavior, with
er callous exploitation of captive sperm,
unethical, surely nothing to celebrate,
nly something to study and wonder at.
lthough I agree that the behavior of the
berated ladies can help destroy out-
noded and mistaken stereotypes in biol-
gy, I do not for a moment believe they
ill in any way serve women as useful
nodels. The book is naive on this score,
nd it is also naive in ignoring a women's
novement whose effects have been felt in
lmost every field, even biology. This
novement, and the powerful emerging
radition of feminist scholarship, made the
vriting, and certainly the publication of
his book in a popular form, possible. We
re deceiving ourselves if we imagine that
"more objective" modes of observation
an by themselves correct old biases.
Overlooked here is a subjective and ideo-
ogical intermediate step, and with it, the
otential for new bias. An awareness of
he existence of liberated ladies in nature
s part of an ongoing dialectical process,
ut not the last word on female natures.

One of the strong points of the book is
he incorporation of much rich material
rom marine biology into the debate on sex
differences. Some of the material from
ther fields, however, is less accurate. It is
rue that female baboons inherit their
anks from their mothers, but this makes
hem matrilineal, not "matriarchal"; no
matter which animal she inherits her rank
rom, a baboon female cannot dominate
ny fully adult male. Old World monkeys
re not, as stated, great apes. Langur
nales are not prevented from taking in-
ants; they virtually never try. Finally, to
ssume that our own ancestresses lost es-
rus to accommodate "husbands" as-
sumes that prehominid females had hus-
ands to begin with—something for
which there is not much evidence.

But these are quibbles and emenda-
ions. On the whole, this lovely book suc-
ceeds in its basic intent: shattering stereo-
ypes. For all those who still think jacana
emales are smaller, more passive, less
sexually assertive than males, the book
should be required reading, and for those
who still would assume out of hand that
he little bird tending the hatchlings laid
he eggs—perhaps even force-fed reading.
Even for those who already know a jacana
ale when they hear one, a pleasurable
eading experience is in store.

*Sarah Blaffer Hrdy is a professor of an-
hropology at the University of Califor-
nia, Davis. Her book* The Woman That Never Evolved *has recently appeared in
paperback.*

Venus Aglow at Dawn

by Thomas D. Nicholson

Venus, west of the sun (to its right), rises first and climbs into the dawn sky before sunrise. Since it passed between the earth and the sun in early April, the planet has been moving steadily to the sun's right. As it turns more of its illuminated part toward the earth, Venus becomes brighter. In early June, it is virtually at its brightest, and by mid-month it reaches its greatest westerly elongation from the sun (measured to the sun's right). These two circumstances combine to make it a spectacular morning star in June. The only negative factor is that it will be far to the south, which keeps it low in the morning. But its brightness and early rising more than compensate for that.

While Venus is shining out in the east as dawn emerges, Jupiter dominates the south, rising before midnight. There is nothing in or near Capricornus to rival Jupiter's brightness as it moves down the western sky in the morning. Mercury, Mars, and Saturn are evening stars in June, but only Saturn can be seen during the entire night. It is up at dusk, in Libra, west (to the right) of Scorpius's bright reddish star, Antares, which rises about an hour later. Both Saturn and Antares move across the sky during the night and set at about dawn. The moon will help locate the two on June 1 and 2, and again at the end of the month. Mercury will be too close to the sun to be seen for most of June, but by the end of the month, it may be glimpsed low in the west just after sunset. Mars also will be lost in the sun's glare this month and hence difficult to view.

The following events are given in local time unless otherwise indicated.

June 1: Tonight's moon is at perigee (nearest the earth) and close to Saturn, in Libra. The planet is above the moon; the reddish star to the east (left) is Antares.

June 2: Full moon is at 10:50 P.M., EST. Antares can be seen dimly through the scattered light below the moon, and Saturn is well to their right.

June 4: The moon rises (about 9:00 P.M., EST) in Sagittarius.

June 7: Mercury is at superior conjunction, passing the sun from right to left and entering the evening sky.

June 7–8: The waning gibbous moon rises with Jupiter at about midnight, moving slowly to the left beneath the bright planet as both climb the morning sky.

June 10: Last-quarter moon is at 3:19 A.M., EST.

June 12: Venus is now forty-six degrees to the sun's right, its greatest westerly elongation during this cycle. Still close to maximum brilliancy, the planet is a very prominent object in the southeast at dawn, bright enough to be seen in daylight. The best daytime view is during the late morning, when Venus is to the west of the meridian (an invisible line that divides the eastern half of the sky from the western half) and at about the same height as the sun.

June 13: Apogee moon, in Aries.

June 14: If you get up early enough, you can see brilliant Venus, just below the crescent moon this morning.

June 15: The earliest sunrise of the year occurs in the Northern Hemisphere today. Latest sunset is on June 27.

June 18: New moon, at 6:58 A.M., EST, is in Taurus, near Mars.

June 21: The sun is at the summer solstice today, the position along the ecliptic in the constellation Gemini where it is farthest north of the earth's equator. Summer begins in the Northern Hemisphere at 5:44 A.M., EST, and the sun is above the

Readers of Natural History are invited to acquire the

Giant Pandas of China

Exceptional new stamps from the People's Republic of China

Stamps, Souvenir Sheet and Presentation Folder shown smaller than actual size

An opportunity to personally enjoy works by China's master artists at the attractive official issue prices you would pay at post offices in China

Found only in China's tangled bamboo forests, the Giant Panda has won the hearts of people the world over. Unique and lovable, the Giant Panda is symbol and substance of an's quest to save the world's wildlife.

And nowhere are the heartwarming appeal and mystery of the iant Panda better understood . . . or more perfectly captured in orks of art . . . than in China itself.

Thus, it is fitting that — on May 24, 1985 — China issued a set four new stamps and a Souvenir Sheet honoring the Giant Panda d featuring works of art by not one, but *two* of China's greatest ving artists.

Available in a beautiful Presentation Folder, the four single amps bear striking paintings by artist Han Meilin, whose acclaimed orks are in demand throughout the world. And, as a crowning uch, the Souvenir Sheet is the creation of the legendary Wu uoren, honorary President of the Central Academy of Fine Art in eijing.

Because of growing worldwide concern for the Giant Panda, it quite possible that these new stamps will become China's most opular stamps *of all time*! As such, they will be sought after by nowledgeable collectors the world over who recognize that China's amps are among the world's most desirable issues.

The *Giant Pandas of China* Presentation Folder — featuring the ew Stamps and Souvenir Sheet in post office fresh mint condition - is available at the official price of only $3.00 — which is the ce value of the stamps plus a modest charge for the Presentation older . . . including historical information and protective display ge. Sets of two Official First Day Covers bearing four of the new amps, plus the Souvenir Sheet are also available . . . at the official ice of $2.

Supplies are limited, so order promptly. Don't miss this opportun- to own the works of two of China's most esteemed artists for the modest face value price of China's new Giant Panda Mint Stamp Presentation Folder! Mail the attached Order Form by June 30, 1985 to: China Stamp Agency in North America, One Unicover Center, Cheyenne, Wyoming, 82008-0003.

horizon for the longest duration of the year. The thin crescent moon should be visible tonight for the first time since the new moon.

June 22: The moon is in Leo. Below the crescent is Regulus, brightest star in Leo.

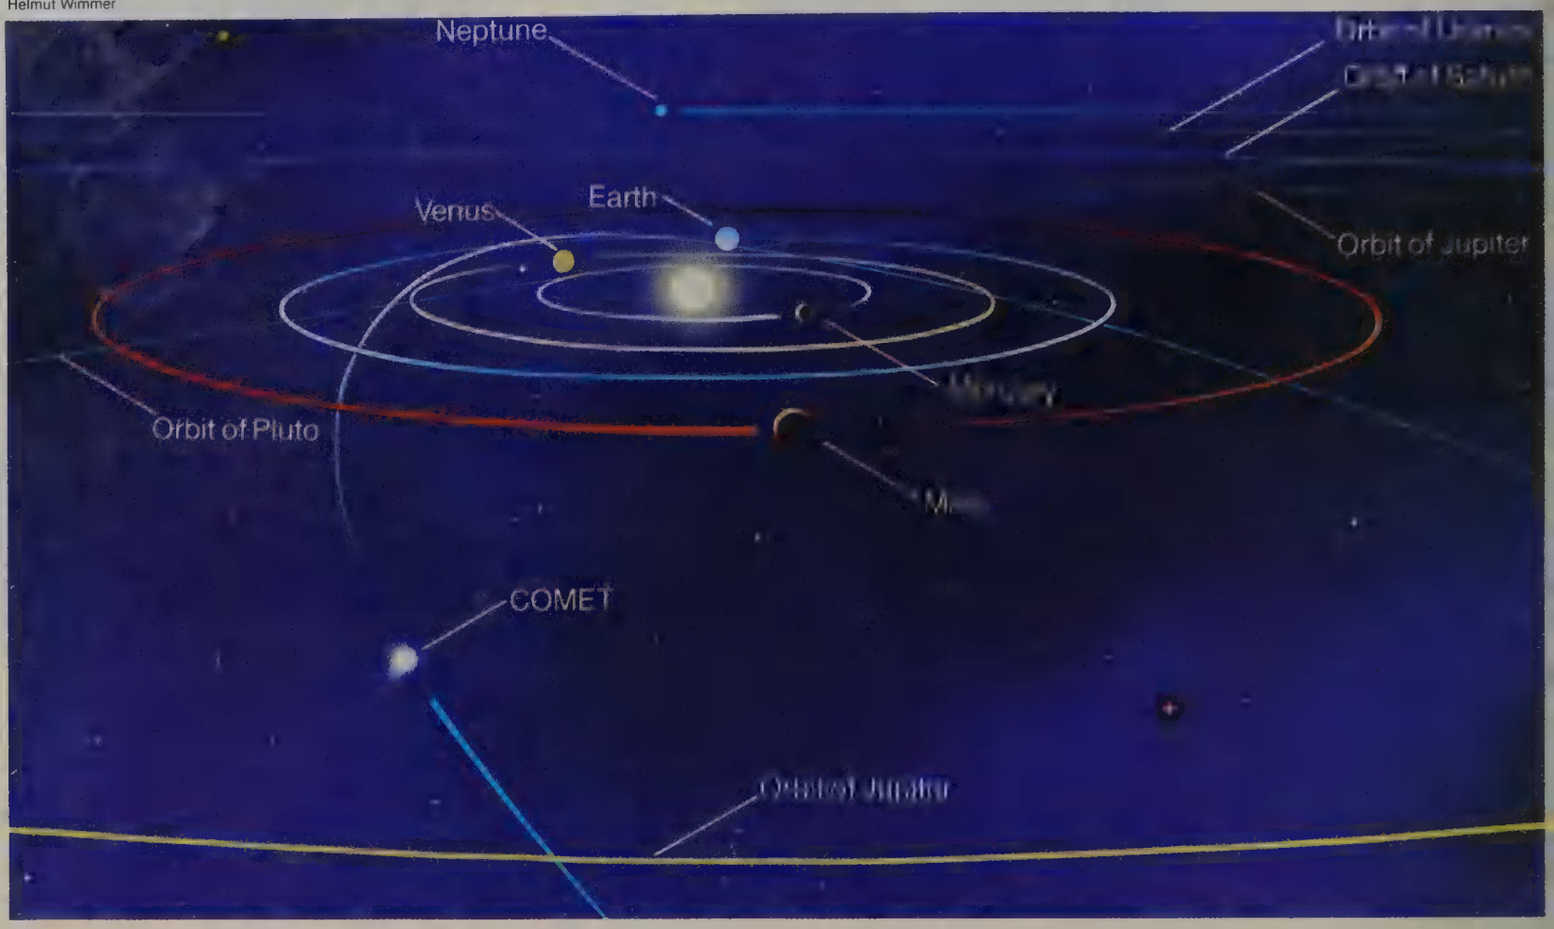
June 25: The moon passed above the autumnal equinox, in Virgo, earlier today, and it reaches first-quarter phase a few hours later, at 1:53 P.M., EST.

June 26: The star just below the moon is Spica, in Virgo.

June 28–29: Watch the moon drift easterly beneath Saturn on the evening of the 28th. It is at perigee on the morning of the 29th.

June 30: The waxing gibbous moon, two days before full, is passing through Ophiuchus. Antares, in Scorpius, to its right, and Saturn, farther right, are virtually in line with the moon.

Helmut Wimmer



Halley's Comeback

The earliest evidence that the forthcoming visit of Halley's comet to the earth's sky is on schedule emerged several years ago. Although the comet wasn't actually seen or photographed then, its presence and location were confirmed by an analysis of radiation in the region. Obviously, this is nothing like the pre-perihelion search during the comet's last appearance, in 1910, when astronomical equipment, materials, and techniques were much less developed. The first sightings then (actually photographs) weren't made until August 1909, eight months before the comet's closest approach to the sun in April 1910.

Because of today's advances in astronomical detection, photographs of the comet's approach this year have been available for some time, though they show nothing but a faint, starlike image drifting slowly through distant stars. Visual sightings were reported as early as February of this year but may not be repeated reliably until this month, and then by dedicated comet watchers with suitable equipment. Still, I wouldn't recommend your rushing out to buy a telescope just yet, no matter how much you may wish to see the comet. As a matter of fact, you may not need a telescope at all.

But given the poor conditions expected during the comet's visit this year and next, you may very well need some optical equipment to improve your chances of seeing it. The most useful equipment for seeing Halley's comet may be a pair of binoculars—not a telescope. With their wide field of view, binoculars let you search more easily and see more of the comet in its field than a telescope would. They are ideal for finding and studying a dim, extended object in the sky. Try them out with the Milky Way, for example, and you will discover that it looks better through binoculars than with a telescope.

A fine instrument for comet viewing is a pair of 7 × 50 prism binoculars. The number 7 is the magnification, low—but you don't need a lot of enlargement. The number 50 is the diameter of each objective, or front lens (about twenty-five millimeters equal one inch), large for good night vision. Prism binoculars (in which the light follows a path through several prisms between the objective lens and the eyepiece) provide a more compact instrument and yield an image that is right side up. The comet should be bright enough to be seen with a pair of 7 × 50 binoculars beginning in late November or early December 1985.

This month's Comet Halley "road map" of the solar system shows the object still crossing the vast space between the orbits of Jupiter and Mars. Remember, of course, that the comet is still several million miles south of those orbits on its own inclined cometary path.

You can get some idea of the vast distances separating the planets in our solar system by noting how long it is taking for the comet to move within the orbit of Mars. It passed inside Jupiter's orbit in January, but won't come within Mars's orbit until the end of November. And this despite its speed of about 43,000 miles per hour at its present position. In mid-June the comet is about 338 million miles from the sun and about 432 million miles from the earth. After entering our morning sky in late May, Halley's comet again moves closer to the earth.

Butterfly Notecards

Send your thoughts to your friends on the wings of six delicate species of butterfly. Produced from extremely rare 18th and 19th century hand-colored engravings in the Rare Book Room of the American Museum of Natural History, these notecards help support the work of the Museum as well. Each group of ten notecards comes with envelopes, and is in its own packet. The entire set of three packets is available for $13.50.

Everyman's Muffins

The scones that are the specialty of Salt Lake City appear to be the only bona fide regional food of Utah

by Raymond Sokolov

I would have liked to include a few scone recipes in this chapter, but once you start on scones where do you stop?

Elizabeth David,
English Bread and Yeast Cookery

Like me, most of you probably grew up thinking of scones as rich muffins. My mother used to bake small circular ones when I was growing up in Detroit. Later, when I lived in England, I ran into similar buns at teahouses.

That was twenty years ago, and I hadn't given scones a second thought until I was recently preparing for a visit to Salt Lake City and noticed in Michael and Jane Stern's *Good Food* that scones were a specialty of the city. This seemed odd, and when I read the Sterns' description of Utah scones, I was sure they were not the scones I had known elsewhere.

Michael Stern was as puzzled as I was. Salt Lake scones were most unsconelike, he told me on the phone before I left: they were fried, puffy, and sometimes split and used as buns for sloppy Joes.

This was confusing but exciting news. Salt Lake is not a rich area for gastronomic research. The Mormons, who settled the city and whose culture is surely still the dominant local strain, were (and are) a religious group drawn from many traditional cultures, not an ethnically coherent population with a settled food tradition. Mormons are zealous missionaries who proselytize among nearby heathen, notably American Indians, and all over the world. This international outlook led them to develop their own script and lingua franca, Deseret. But on the culinary level, they seem to have been content to continue the diet the first Mormons brought with them in the second half of the nineteenth century. Since the early settlers departed from the Midwest, it isn't surprising that today's typical Mormon food should closely resemble midwestern farmhouse food.

In Salt Lake, I was able to verify this assumption at the Mormon world's closest approximation to an official restaurant, a cafeteria called the Pantry, situated in the Lion House, a former home of Mormon patriarch Brigham Young. The building is not open to the public but serves the Mormon community as a sort of banquet hall and dining club. No fewer than five wedding parties were celebrating the day I was taken there.

From years of such prominence in Mormon feasting, the Lion House kitchen has taken on a special luster among the faithful. Reservations for the banquet rooms are said to be made years in advance. It seems reasonable to say, then, that the kitchen of the Lion House represents Mormon traditional cooking at its best. And judging by what I ate at the Pantry and by the recipes collected in 1980 for *Lion House Recipes,* Mormon cooking is an unreconstructed expression of mainstream middle American food: jello salads, pies, meat and potatoes.

Lion House Recipes does contain some relatively exotic dishes, such as Greek salad and Mexican taco salad. What it lacks almost completely is purely local food ideas not imported from somewhere else. It would be unfair, however, to blame the lack of purely Utah recipes only on the Mormons. You will find almost no bona fide regional recipes in the secular counterpart to *Lion House Recipes,* a compilation entitled *What's Cooking in Utah Kitchens,* edited by Donna Lou Morgan, food editor of the *Salt Lake Tribune.*

There are, to be sure, original dishes, such as Chicken Porter Rockwell (a chicken pie), and various other concoctions culled from family recipe files, but the only dish in either of these books that seems to have developed in Utah and taken root in the regional culture is the anomalous fried bread called scone.

In Utah, by the evidence of both local cookbooks and three local restaurants, the scone starts out as a yeast-raised, sweet dough that is cut into 2-by-2-inch squares (or other shapes of similar surface area) and deep-fried. The most popular method of service is with butter and honey. That is how I ate a midmorning scone at Johanna's Kitchen in a mall at Jordan, Utah. They didn't bother to bring honey at the Pepper Tree in Salt Lake, but they did advertise a free scone with each breakfast "entrée" on the sign out front.

Clearly, the Utah scone is not a vanishing bread. Certainly not at the two-restaurant chain in Salt Lake City called Sconecutter. At these twenty-four-hour drive-ins, the Utah scone rises to challenge the doughnut and the hamburger bun as a fast-food commodity. Cooked on the spot from yeast dough, the scones come out crisp, puffy, and rectangular. The dough inside is airy and pleasantly chewy. But are they scones in the normal sense? And if not, where do they come from? How did they start?

Traditional English scones are too diverse to classify with much certainty, as Elizabeth David warns us. But they do generally qualify as muffinish quick breads, and mostly they are baked. According to the Oxford English Dictionary, scones (derived from the Middle Low German *schonbrot,* or fine bread) are baked, cooked on a griddle stone, or even fried (but not deep-fried). Yeast does crop up sometimes, for example, in Jane Grigson's recipe for Northumbrian wholemeal scones in *English Food.* But no traditional British scone I have ever eaten or read about comes close to resembling the Utah scone. So it seems improbable that early Mormons of British extraction imported the deep-fried scone to their New World Zion.

When I asked her about it, Donna Lou Morgan guessed that pioneer Utah cooks, who were inveterate bread bakers, had taken to frying some of the yeast dough they often had on hand. She remembered her own mother pinching off pieces of bread dough and frying them, but Morgan's own recipe for scones, which is very much like the Lion House's, is not based on a conventional bread dough. It is richer and sweeter and has chemical raising agents in it, undoubtedly to boost the puffing of the scone as it fries.

The first time I ate a Utah scone, I was certainly not reminded of bread or of traditional muffin scones. I thought instantly of two other puffy fried breads popular in

NEW YORK, NATURALLY!

(Designed exclusively for Members of the American Museum of Natural History)

Whether your first love is art or archaeology, elegance or evolution, Tiffany or Tyrannosaurus rex, the stars of the heavens or the stars of Broadway, you'll find it in our Members' New York Weekend. For three exciting days and two wonderful nights, a great city and a great Museum will be all yours.

- **Two nights in one of New York's finest hotels:** Stay at The Waldorf Astoria, The Parker Meridien, or The Plaza. Minutes away from New York's famed theater, shopping, and eating districts and only a short ride away from the Museum itself.
- **Two complimentary meals:** Enjoy a full breakfast at your hotel and a leisurely lunch in the Museum's charming greenhouse-style restaurant.
- **The Official Guide and a Highlights Tour:** As soon as you make your reservations, we will send you the Museum's Official Guide to introduce you to our fabulous treasures. And when you arrive at the Museum, take a Highlights Tour, which provides fascinating insights into the Museum's most popular halls. Or savor the Museum at your own pace. Journey through halls filled with gems, dinosaurs, myriad life forms, and peoples from all over the world. The Star of India sapphire, wolves hunting in the night, ancient totems of the Northwest Coast, and Mayan sculptures are just a few of the Museum's varied wonders. At the end of your visit, relax in our private Members' Lounge or take advantage of your Members' discounts at Museum gift shops.
- **Special Exhibitions:** The Museum presents an exciting schedule of special exhibitions throughout the year. Through July: *Maya: Treasures of An Ancient Civilization* and *John James Audubon: Science into Art.*
- **Free Planetarium and Naturemax Tickets:** Journey through the heavens in the Planetarium's famed sky theater and enjoy the film experience of a lifetime at Naturemax, with its movie screen sixty feet wide and over four stories high.
- **Personalized Service:** The Members' Service Desk will help customize your weekend to suit your needs and tastes. They'll be glad to arrange theater or concert tickets, reservations at New York's top restaurants, a carriage ride through Central Park, or tours of the town.
- **Discount air fares:** Special rates are available on American Airlines, the official airline of the Members' New York Weekend.

Tour Program Price: $92.50 per person, per night. Tax included. Based on two nights double occupancy. Rates also available for families and individuals.

Call or write today for reservations, brochures and more information.

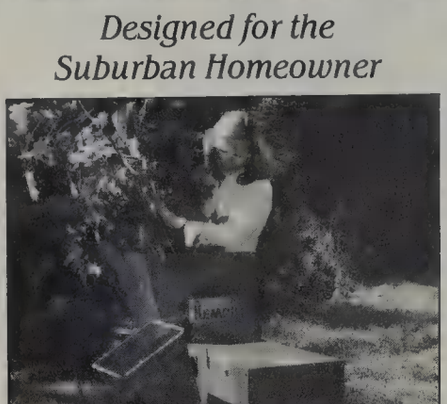
Gardeners Love

America's First SHREDDER/CHIPPER

Designed for the Suburban Homeowner



Make Your Own Mulch, Compost and Natural Fertilizer...FREE!

Protect, beautify and feed your valuable flowers and shrubs. Enjoy bountiful harvests of fruits and vegetables. *Recycle* organic matter into nutrient-rich compost, mulch and fertilizer. A Kemp Shredder/Chipper chips branches (up to 3" thick!), pulverizes brush, fallen leaves, kitchen scraps (bones, too!), old plants, etc. into millions of tiny pieces . . . in seconds! Easily, safely, economically.

- **Grinds** for instant compost
- **Shreds** for valuable mulch
- **Chips** for decorative wood chips
- **Saves** fertilizer costs
- **Reduces** clean-up time
- **Enriches** soil...naturally
- **Boosts** garden yields
- **Beautifies** your yard

the West: Navajo fry bread and New Mexican sopaipillas (see recipes). The taste of both these regional "breads" is very close to the taste of Utah scones. Yes, the shapes and textures vary a little. But with the sopaipilla, there is an extra link. Like Utah scones, sopaipillas are served with honey.

Until some researcher makes a lucky strike in a Mormon woman's diary or a pioneer cookbook, we are never going to know for sure how it is that Navajos, Chicanos, and Mormons ended up eating similar fried breads. It could all be coincidence, but in the absence of hard facts, it is tempting to construct an explanatory scenario that will connect all the fried breads so popular in the mountain time zone, from Bountiful, Utah, to Hatch, New Mexico. Here is one.

Let us suppose that both the Navajo fry bread and the sopaipilla predate the Utah scone. They are simpler and history is on their side. Both Navajos and Hispanicized New Mexicans were in their present regions long before the Mormons. Their fry breads are almost identical, and so it makes sense to look for an archetypal southwestern fry bread from which both descend. Now since most culinary ideas in the U.S. Southwest moved there from the south, when Mexico controlled the area there ought to be a Mexican ancestor for the sopaipilla and for the Navajo fry bread.

In fact, there is one. Diana Kennedy located sopaipillas in the Mexican state of Chihuahua, which shares some of its northern border with New Mexico. Sopaipillas are uncommon there, but they are called sopaipillas and are similar to those eaten in New Mexico, except that in Chihuahua they aren't made with a chemical raising agent (or with yeast). This greater simplicity argues in favor of Chihuahua as the birthplace of American fry bread.

Still, it may be that the Chihuahuan sopaipilla is a later simplification of a New Mexican original. But I doubt that. Common sense tells me that the baking soda now used by Navajos and Chicanos came to them at a late date from the intruding Anglo world. The primitive fry bread now preserved in Chihuahua was probably once indigenous to the entire region we are talking about and now survives only in Chihuahua because of its remoteness from outside influences. Most probably then, when Mormons first came into contact with southwestern Indians, the

Buttermilk Scones

(Slightly adapted from *Lion House Recipes,* compiled by Helen Thackeray, Shadow Mountain, P.O. Box 30178, Salt Lake City, Utah 84130, $9.95)

- 1 quart buttermilk
- 2 packages (2 tablespoons) dry active yeast
- ¼ cup sugar
- 2 eggs, beaten
- 2 tablespoons oil
- 1½ teaspoons salt
- 1 tablespoon baking powder
- 1 teaspoon baking soda
- 8 cups flour
- Oil for frying

1. Heat buttermilk until warm.
2. Meanwhile, soften yeast in ¼ cup lukewarm water.
3. In a large bowl, combine buttermilk, sugar, eggs, oil, salt, baking powder, baking soda, and 4 cups flour. Add yeast. Beat until smooth. Add remaining flour to make soft dough. Allow to rise, covered, until doubled in bulk. Punch down and place in refrigerator overnight.
4. When ready to fry, heat oil to 375 degrees. Roll dough out on a floured board until ¼ inch thick. Cut into 2-by-2-inch squares.
5. Fry a few scones at a time. Stretch out each piece a little before frying and drop into hot oil. Fry on one side until golden; turn with tongs and fry on other side. Drain on paper towels. Serve hot with honey and butter.

Yield: 60–100 scones, depending on size of squares

Note: The dough will keep in the refrigerator for 3 to 4 days. Keep punching down and cover tightly with foil or a damp cloth.

Indian Fry Bread

(Slightly adapted from *American Indian Food and Lore,* by Carolyn Niethammer, Collier)

- 4 cups flour (all white or ½ white and ½ whole wheat)
- 1 tablespoon baking powder
- 1½ teaspoons salt
- 1½ teaspoons cooking oil

1. Mix the flour, baking powder, and salt. Add oil and enough water to make a soft dough. Knead with a floured hand until the dough has some spring. Shape into balls about 3 inches in diameter. Pat each ball into a flat cake and keep patting and stretching the dough into a thin sheet, 10 to 12 inches in diameter. This takes practice.
2. Fry each round in very hot fat, turning once, until golden and puffy.

Yield: 12–14 bread puffs

und them eating an unleavened fried ead that puffed up in hot oil.

Inevitably, they tasted it and liked it. ormon women then tried to duplicate e recipe and added a whole battery of sing agents they knew about from Eng- h baking. They put in buttermilk be- use its mild acidity was necessary to ac- ate baking soda and make it give off rbon dioxide. They added eggs and gar and ended up with a delicious and ginal bread, related in kind to the *ignet* family, but a thing unto itself. And cking a name for the thing, they remem- red scones, quick sweet breads from ck home that were also cut into individ- l serving pieces before cooking.

This is only a hypothesis, not a substi- te for real evidence. At any rate, the ah scone flourishes on its native ground, rd by its Indian cousins. And no matter w Navajo bread, sopaipillas, and Utah ones actually came about, it is the case at the Four Corners, where Utah, Ari- na, New Mexico, and Colorado meet, is e fried bread capital of the world.

aymond Sokolov is a writer whose spe- l interest is the history and preparation food.

Sopaipillas

Adapted from *The Feast of Santa Fe,* Huntley Dent, Simon and Schuster)

1 cup plus 2 tablespoons flour
1 teaspoon baking powder
¼ teaspoon salt
2 tablespoons lard or vegetable shortening
Oil for deep frying

Combine the flour, baking powder, and salt in a mixing bowl.

Cut the lard or shortening into the flour mixture until flaky.

Pour in ¼ cup plus two tablespoons water all at once and mix quickly with a fork to make a sticky dough.

Flour a board and turn the dough out on it. Knead 10 to 12 times, until dough is no longer sticky. Cover with plastic wrap and let rest 15 minutes.

Roll out half the dough to a 10-by-5-inch rectangle. Cut into two 5-by-5-inch squares (or into smaller squares or triangles if desired).

Heat oil to 400 degrees.

Fry one square at a time. Drop into oil and hold submerged with a metal spatula until it puffs. Release, let brown, and then cook on other side until browned. Drain and serve or keep warm in a 200-degree oven.

Repeat with other half of dough.

Yield: 8 small or 4 large sopaipillas

Fitness Master LT-35

TOTAL SYSTEM FOR CARDIOVASCULAR FITNESS.

Simulates cross-country skiing, regarded by fitness authorities as the top cardiovascular exercise. Rated higher than jogging, swimming, biking or rowing.

- Fluid motion — no jarring impact on bones and joints. Avoids running related injuries.
- Excellent for weight control and body tone.
- Stable, unit rests flat on floor. Lightweight for portability. Weighs only 35 lbs.
- Easily stored. Folds to 5 inch height. Slips under a bed or stands upright in closet.
- 30 day home trial. 2 year warranty.
- Can be used by men and women regardless of size or weight. Height and resistance adjustable.

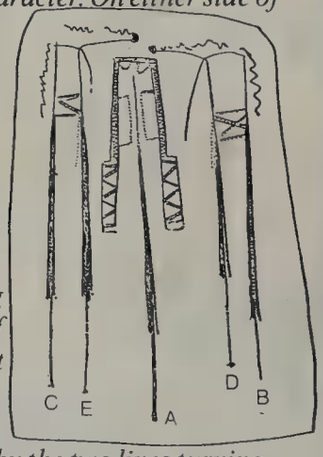
From Siberia with Love

One of the rarest and most obscure artifacts in the Gardner D. Stout Hall of Asian Peoples is a small scrap of birch bark, with a red ribbon tied to one end, covered with incised geometrical designs. This scrap is actually a letter—a love letter—written by two girls of the Yukagir (formerly Yukaghir) tribe, a small group of people who once lived in northeastern Siberia near the shores of the Arctic Sea. The letter, which was directed to the anthropologist who was studying the tribe, is written in a pictographic language that is similar to an early stage in the development of our own alphabetic system and may hold important clues to the development of writing in general. It is believed to be the only genuine Yukagir love letter in existence, although a number of copies can be seen in Leningrad.

The letter is an unusual example of the misunderstandings that can sometimes arise between anthropologists and the people they are studying. (New insights and information can often spring from such misunderstandings.) It was given to the Museum by Waldemar Jochelson, a Russian ethnologist, who spent many years living among the remote tribes of Siberia. The letter had remained in an anthropology storeroom for nearly eighty years when it was "rediscovered" by Cynthia Wilder, an assistant in the Anthropology Department, during preparation for the Hall of Asian Peoples.

Jochelson came to study Siberian tribes almost by accident. He had been exiled to Siberia by the czar because of his revolutionary activities. Once in Siberia, how-



In this Yukagir love letter, written to anthropologist Waldemar Jochelson, people are represented by thin decorated lines. Jochelson (a) is depicted standing in front of his house. He occupies a position of status, as evidenced by the height of the character. On either side of him (e and d) appear the two jilted Yukagir girls. Both send passionate thoughts to him—shown as the two faint lines emanating from the tops of their heads. But Jochelson rejects their love, indicated by the two lines turning back in a series of squiggles. The two figures on the far left and right (c and b) are Jochelson's interpreter, Alexander Dolganoff, and the Cossack guide. The two girls point out that they achieved more satisfying relationships with them. One relationship is strong, indicated by the X between the two characters; the other is more casual, represented by the backward Z between them.

1986 Discovery Tours

Special Museum Cruise

Voyage through Melanesia: New Guinea to Fiji
February 16 to March 6, 1986

Join Dr. Thomas D. Nicholson, Director of the American Museum, and other outstanding lecturers on a luxury cruise through the most intriguing island group in the world: New Guinea to Fiji. The cultural and natural history is extraordinary.

Exquisite artwork, fascinating traditions and unique performances (sing-sings) will be experienced on land and discussed while at sea with renowned anthropologists and art historians. Stunning coral atolls and volcanic islands will be explored with expert marine biologists and geologists.

You will travel by luxury cruise vessel, the *Illiria*, with only 48 cabins: the amenities of the finest giant cruise liners and the intimacy of your own private yacht.

The combination of an excellent itinerary, lecturers and cruise vessel results in a splendid experience. Join us!

If you wish to receive a brochure describing the complete itinerary, deck plan, lecturer team, prices, etc., call (212) 873-1440. Or, complete the attached coupon and mail it to Discovery Tours as indicated.

ever, he was allowed to travel and work, although at times he was shadowed and harassed by the czar's secret police. To put his exile to good use, he began doing geographical and ethnological fieldwork for the Imperial Russian Geographical Society in 1895.

In 1897, Franz Boas, then an assistant curator at the American Museum, heard about Jochelson's work through the Russian Academy of Sciences. In an effort to prove the theory that the American Indian had originally migrated from Asia to North America by crossing the Bering Strait, Boas began organizing an expedition to gather information about the tribes living along the rim of the North Pacific Ocean, from Washington State to Alaska, Siberia, northern China, and Japan. Because of Jochelson's previous work with Siberian tribes and his fluency in both Russian and German, Boas hired him and his wife, Dina Brodsky Jochelson, to conduct research among the Yukagir, Tungus, Koryak, and other remote Siberian tribes. Boas instructed them to collect everything they could—including artifacts, myths, photographs, dictionaries, grammars, wax-cylinder recordings of songs, anthropometric measurements, bones, and graveposts. He also purchased some of Jochelson's earlier collections, including those made among the Yukagir on his first trip in 1895–96.

Boas saw the fragile aboriginal cultures of the North Pacific rim poised at the edge of extinction. In many ways what was happening in Siberia was a mirror image of what was happening in the American West—and Boas knew that in both cases the results would be tragic. His overriding desire, shared by Jochelson, was to save every possible thing related to these societies for future study and, ultimately, the common heritage of humanity.

Of all the tribes Jochelson studied in Siberia, he felt a particular fondness for the Yukagir. Jochelson saw them as a mild-mannered people who believed in honesty, kindness, and hospitality and abhorred rudeness, foul language, and personal violence. These qualities resulted in their being exploited and abused by the Cossacks, by Russian settlers, and especially by the local priests and contributed, Jochelson felt, to the rapid decline and assimilation of Yukagir culture.

The love letter is one of thousands of artifacts Jochelson saved from the Yukagir, some of which are on display in the Siberian section of the Hall of Asian Peoples. The history of the love letter is curious

At the American Museum

Identification Day

Once again, the Museum will hold its popular *Identification Day.* On June 1, visitors can bring in their unknown rocks, shells, fossils, insects, pottery, artifacts, and just about anything else—except for gemstones—to Museum scientists, who will do their best to identify them. The program, which will run from 1:00 to 5:00 P.M. in the Dana Education Wing, is free to all Museum visitors.

Cruise Around Manhattan

On Tuesday, June 4, from 5:30 to 8:30 P.M., geologist Sidney Horenstein will host a three-hour, twilight boat trip around Manhattan to survey the unusual geology of the island and the surrounding Palisades. The Hudson is North America's most southerly fiord, and its geology is unique along the Eastern Seaboard. Cost of the trip is $18 for members, $20 for nonmembers. Contact the Education Department for more details.

Cruise into New York Bay

On this three-hour cruise around New York Bay, participants will view forts from the War of 1812, the glacial moraine that is Brooklyn, and learn the origin of the Narrows under the Verrazano Bridge. Sidney Horenstein will lead this unusual tour of the geology, flora, fauna, and history of the Upper Bay area. It will take place on Tuesday, June 11, from 5:30 to 8:30 P.M. Cost is $18 for members, $20 for nonmembers; contact the Education Department for details.

Queen of Heaven

The Membership Office will present *Inanna: Queen of Heaven and Earth* on Friday, June 7, at 8:00 P.M. in the Kaufmann Theater. The story of the goddess Inanna's life was recorded 4,000 years ago on clay tablets and wall murals from Sumer and Babylon. Storyteller Diane Wolkstein will recount the saga of Inanna; Geoffrey Gordon will provide musical accompaniment. Tickets are $8 for members and $10 for nonmembers; for more information call (212) 873-1327.

Bobcats and Bobkittens

This month's *Members' Family Program* will focus on the bobcat. Hope Ryden will show slides of this elusive animal and talk about its life cycle, behavior, and range, as well as current efforts to save it from fur hunters and habitat destruction. The free program, open only to members, will take place on Tuesday, June 25, at 7:30 P.M. in the Auditorium. Tickets are required.

chelson received it during his first stay h the Yukagir in 1895–96, shortly after was exiled to Siberia. He had two comnions on this trip, a Yukagir interpreter med Alexander Dolganoff and a Cosk guide.

While the Yukagir frowned on immody and were very bashful in discussing xual matters, there was considerable edom in relations between the sexes. rginity was not important to the Yuka-, and most girls set up their own tents at berty and quietly began receiving lov-. One custom in Yukagir society was to ovide an unmarried girl to any man who s away from his wife. A father would rmally offer his daughter's bed to a visng man as a courtesy. If the man was imrtant, the daughter would consider it an nor to share her bed with him. However, was completely up to the girl whether e had sex with the man. If she found him jectionable, she was perfectly free to eave her loin cloth on" (according to a ukagir proverb).

Jochelson spent his first four months nong the Yukagir learning their lanage in the house of a tribal elder who ed near the Yassachna River. The elder d his wife had an adopted daughter of out seventeen or eighteen years of age. s soon as Jochelson settled in, he noticed at the usual nightly visits of young men the girl had ceased. After a while the fe of the elder seemed puzzled by chelson's sexual abstinence. She said, t seems that among you, men can live thout wives." Jochelson explained that here he came from, a married man was pposed to remain faithful to his wife, en when he was away for a long time. ccording to Jochelson, the woman reied, "Well, it seems that the Russians re have different customs. They go to her girls and wives, even when they have eir own wives with them." Later, his inrpreter told him that the elder's adopted ughter was very offended that Jochelon had not visited her, as was the custom r a male guest in her parents' house.

That summer, at a camp near the Yaschna River, a similar misunderstanding curred. "In this village," Jochelson rote,

ved the blacksmith Shaluguin, an old ukaghir, who had a large family, among em several daughters. The youngest was nsidered to be the prettiest on the river assachna. For a long time I intended to ke her photograph in holiday dress, and eant to do it before my departure; but, as e was then staying with her relatives in nother settlement, I asked the old man to nd a boat for her. In spite of the fact that I xplained to the old man what I wanted his daughter for, my request was understood in another way. The girl arrived late in the evening, and I put off taking the photograph till the next morning. My canvas tent was standing near the skin tent of Shaluguin. Imagine my astonishment next morning when, stepping out of my tent, I noticed between it and that of Shaluguin a separate small tent, which the girl was just then taking away! She was in a very angry mood, and my photographs were not successful. Afterwards my interpreter told me that the young men laughed at the girl for having uselessly put up a separate tent.

When Jochelson left the Yassachna River, the two spurned Yukagir girls wrote him the love letter. It told the story of their frustrated romance with the anthropologist and, according to Jochelson, was given to him with no trace of jealousy or bad feeling.

Jochelson kept this letter in his personal collection and later was not able to locate any similar examples. In 1901 and 1902, when he returned to the Yukagir on a trip sponsored by the American Museum, drastic changes had taken place. The tribe had been decimated by disease and starvation, and Jochelson spent much of his time trying to get medical supplies, food, and assistance to them. In the face of this overwhelming change and misfortune, the Yukagir had abandoned a number of traditional customs, including, it seems, the practice of writing love letters. In his ethnography, *The Yukaghir,* published by the Museum in 1910, Jochelson speculated on the future of the tribe:

> The Yukaghir, who in the past, according to all collected information, were a fairly numerous tribe, at the present time consist . . . of a few hundred people scattered in small groups over an enormous area, which groups are dying out rapidly. . . . This tribe is therefore on the verge of complete physical and ethnic extinction.
>
> The study of a tribe . . . insignificant in numbers and having no future—was a difficult, and, from a practical point of view, a thankless task. But the science of ethnology recognizes that a knowledge of small tribes is equally as important as that of great peoples. In fact . . . information about the life and history of a tribe which is becoming extinct is particularly important.

The birch bark love letter is just one of eight million artifacts in the Museum's anthropology collections. These artifacts, however, are not merely a collection of inert objects; each was once very important to the person who created it and owned it. Like the Siberian love letter, each one carries with it a trail of history, of information, and of meaning.

A Sealed Fate

Driving along California's coastal highway last year, Peggy and Erwin Bauer passed the place where the Russian River joins the ocean. There, they noticed quite a few harbor seals lying on a sand bar that had been exposed at low tide. The Bauers decided to investigate this scene. After a steep descent, they arrived at the sand bar and found about forty seals hauled out on the sand. Others were swimming nearby. At that point, an eel jumped out of the river and thrashed helplessly on the bank. A harbor seal climbed out after it and, taking the prey in its mouth, slid back into the river to devour it. As the Bauers watched, more and more eels began to pop out of the water along a fifty-yard stretch of river immediately upstream. Each was pursued, caught, and eaten as before. After observing and photographing this foraging behavior for some time, the Bauers realized what was happening. The seals were chasing the eels into the shallow areas at the edge of the river and then forcing them out.

The Bauers had never seen such behavior before but, quite possibly, no one else has either. According to Jake Houck, a marine mammalogist at Humboldt State University in California, seals are not known to prey on eels this way. "If they were eels, they would have to be lampreys," Houck says. "I don't doubt the report is correct. But I have never heard of anyone reporting seals chasing eels out of the water that way."

Houck points out, however, that harbor seals are opportunistic feeders that will take any food item that appears in abundance in their environment, including octopus and salmon. Why were so many eels passing through the area? "They were probably making an upstream spawning run," Houck says. "The eels are at the end of their life cycle. They are looking for gravelly areas where they will spawn and die."

Additional Reading

Underwater Pollination (p. 36)

Paul Alan Cox's "Spore Theory, Random Motion, and the Convergent Evolution of Pollen and Spore Morphology in Aquatic Plants" (*American Naturalist,* vol. 121, pp. 9–31) considers the nature of random motions and the theory of random search, which suggests that search efficiencies would be much greater for aquatic spores that have large, long axes and move in planes (such as water surfaces) rather than in three dimensions. Sea grasses flower underwater, shedding pollen that is borne from plant to plant by waves. John Pettitt, Sophie Ducker, and Bruce Knox explore the differences between the sea grass system of reproduction and that of land-based plants in "Submarine Pollination" (*Scientific American,* March 1981, pp. 134–43). C.T. Ingold's *Spore Liberation* (Oxford: Clarendon Press, 1965) explicates fungal spore dispersal and is abundantly illustrated. A number of general books on pollination explain how it occurs underwater; these include Michael Proctor and Peter Yeo's *The Pollination of Flowers* (New York: Taplinger, 1973) and K. Faegri and L. van der Pijl's *The Principles of Pollination Ecology* (New York: Pergamon, 1972).

Derelict Ships (p. 42)

Henry Stommel, the oceanographer who did most of the basic theoretical work on the wind-driven circulation of the Gulf Stream, wrote one of the best books on the current: *The Gulf Stream: A Physical and Dynamical Description* (Berkeley: University of California Press, 1965). In honor of Stommel's sixtieth birthday in 1981, the MIT Press, Cambridge, published *Evolution of Physical Oceanography,* edited by Bruce A. Warren and Carl Wunsch (Cambridge: The MIT Press, 1981). One chapter, by Nick Fonofoff, updates Stommel's data on the Gulf Stream. L. Valentine Worthington, who recently retired after spending about forty years working on the North Atlantic, provides an overview of its water-mass properties and other hydrographic data in *On the North Atlantic Circulation* (Baltimore: The Johns Hopkins University Press, Oceanographic Studies No. 6, 1976). *Edies in Marine Science,* edited by Allan Robinson (New York: Springer-Verla 1983), summarizes current knowledge eddies, and includes some articles on t Gulf Stream, such as Philip L. Richar son's "Gulf Stream Rings" and D. Watts's "Gulf Stream Variability." Ric ardson's "Eddy Kinetic Energy in t North Atlantic from Surface Drifter (*Journal of Geophysical Research,* v 88, pp. 4355–67, published by the Ame can Geophysical Union, 2000 Florida A enue NW, Washington, D.C. 20009) giv measurements of drifting surface buoys the Gulf Stream. Finally, Capt. W Lewis Parker explores the history wooden schooners in "The Operation a Management of the Great New Engla Schooners 1870–1900" (*Maritime Mon graphs and Reports*, No. 5, published the National Maritime Museum, Gree wich, London SE10 9NF).

Bats (p. 52)

Ten bat experts contributed to *Ecolo of Bats* (New York: Plenum Press, 198 an authoritative account edited Thomas H. Kunz. Chapters cover the i portance of roosts; bat reproductio growth and survival; evolutionary alter tives in the physiological ecology of ba ecological aspects of bat activity rhythm morphology; echolocation, insect hearin and feeding ecology of insectivorous ba foraging strategies of plant-visiting ba coevolution between bats and plants; a ecology of insects ectoparasitic on ba *Biology of Bats,* edited by William Wimsatt (New York: Academic Pre 1977), is a multivolumed, comprehensi summary of our knowledge of Chiropte the second largest order of mammals number of species and possibly the mo abundant. It assembles most of the bas anatomical, physiological, behavioral, a ecological information on this group. Pa ticularly relevant to this issue's article bats is J.W. Bradbury's "Social Organiz tion and Communication," in volume 3 the series. See also Daniel H. Janze "Dispersal of Seeds by Vertebrate Gut in *Coevolution,* edited by D.J. Futuyn and Montgomery Slatkin (Sunderlan MA: Sinauer Associates, Inc., 1983, p

62). *The Web of Adaptations*, by
sh ornithologist David W. Snow
v York: Quadrangle/The New York
s Book Co., 1976), an account of the
vior of a number of birds of the
rican tropical forest, devotes some
ters to an exploration of the ways a
es is fitted to life in its environment.

afalaya Delta (p. 60)
odney D. Adams and Robert H.
nann's "Emergence of the Atchafa-
Bay Delta," published in 1980, is the
nontechnical report specifically deal-
vith the Atchafalaya. It is available
3 from its publisher: Louisiana Sea
t, Center for Wetland Resources,
siana State University, Baton Rouge,
siana 70803. Cite publication num-
LSU-T-80-02 when ordering a copy.
e Lockwood's *Atchafalaya: Ameri-
Largest River Basin Swamp* (Baton
ge: Beauregard Press, 1981), a coffee-
-type book with lots of pictures of
siana's delta country, concentrates on
Atchafalaya's inland floodplain.
nd of the River," by Douglas Lee (*Na-
l Geographic*, August 1983), is about
Mississippi River Delta area and the
le who live there. It talks about the
rioration of the Mississippi River
a and recounts the history of the pre-
s deltas. *Geographical Magazine*, a
lar British publication, ran Eugene
er and Edward Maltby's "Louisiana
e Wetland State" (February 1983),
h explains the importance of wet-
s for wildlife and fisheries resources
the problems that have been created
uman impact on the habitat. *Rivers of
World*, by Eberhard Czaya (New
: Van Nostrand Reinhold, 1981), is a
ly written, scientifically accurate
book that elucidates delta formation,
dplain basins, river morphology, and
r such data. Finally, the most enjoy-
and probably the most famous book
t the Mississippi is Mark Twain's
on the Mississippi (New York: Pen-
Books, 1984). Particularly interest-
n light of this issue's article is Twain's
ription of his boat trip down the
afalaya during a flood.

"The desert equivalent of Aldo Leopold's 'Sand County Almanac.'"
—James H. Brown, University of Arizona

Sonoran Desert Spring

John Alcock

This beautifully illustrated book is a celebration of the joy of observing desert plants and animals over the course of a season. It splendidly evokes the bittersweet sadness of the wild and the lure of a harsh and unfamiliar environment.

"Alcock conveys a feeling for the living things of the desert in the way that Edward Abbey does for the inanimate features."—Bernd Heinrich, author of *In a Patch of Fireweed*

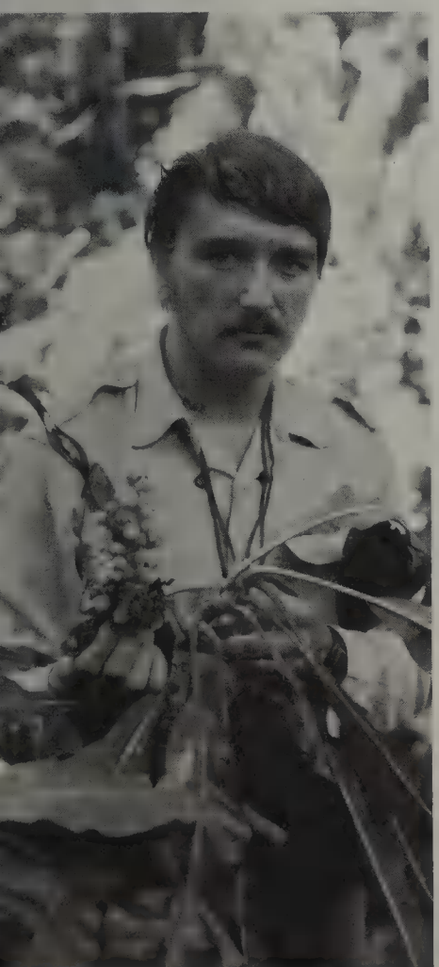
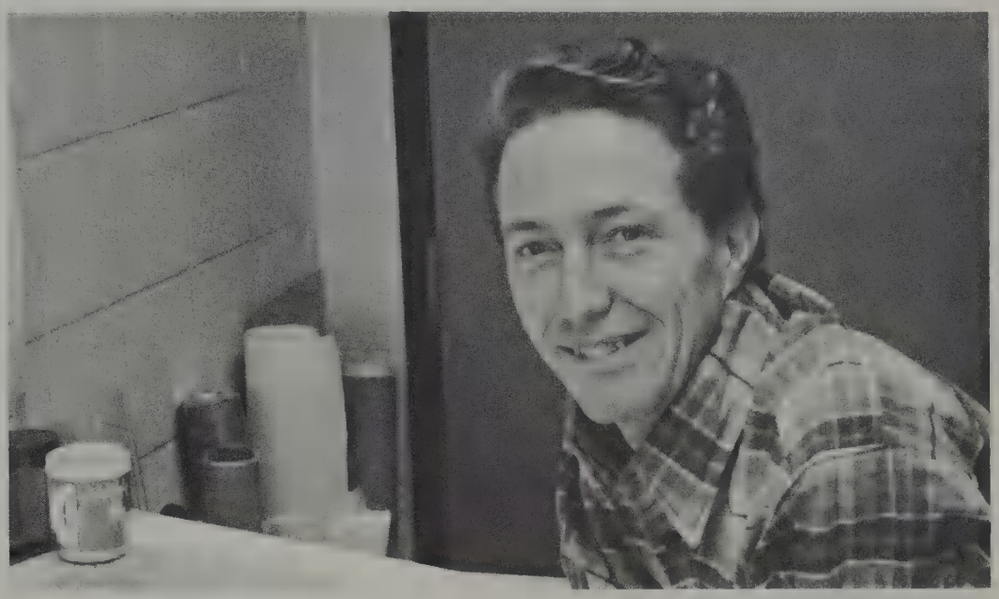
G2

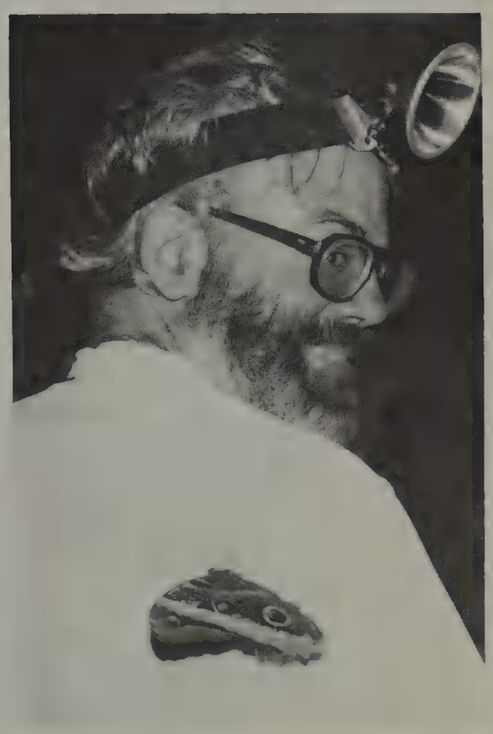
orn into a Mormon family in Utah, **l Alan Cox** (page 36) interrupted his ergraduate work at Brigham Young versity to go on the traditional two- Mormon mission. His mission took to Samoa where he learned some nesian dialects and found, as Dar- had in the Galápagos, "that the hanisms of nature seem exposed." graduate student in biology, Cox re- ed to Samoa to do work on tropical ogy. Since getting his Ph.D. at Har- l in botany, he has gone back to Sa- and to other locations in the South ific many times to study the local . "They are not very well known," ays. "Not many botanists work in the th Pacific. I have the advantage of aking the languages. And the climate onderful." Cox's article in this issue e second he has written for *Natural tory* (see "Sex and the Single wer," November 1983).





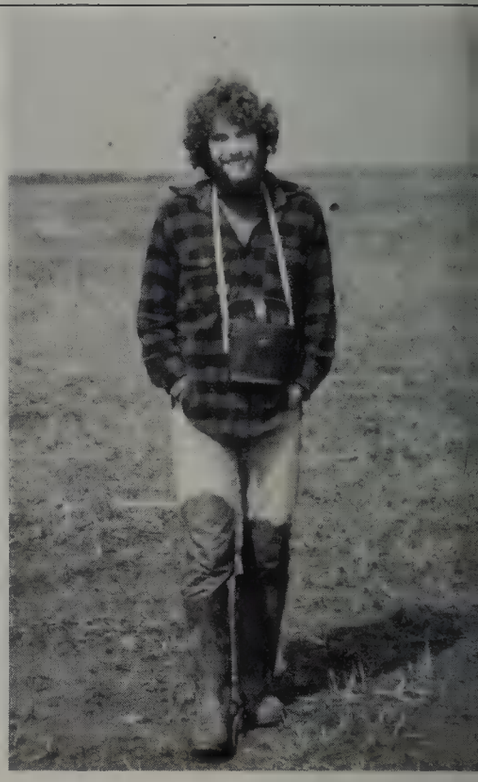
"I usually go on one cruise a year to do hydrographic sampling," says physical oceanographer **Philip L. Richardson** (page 42). "On the cruises we launch surface buoys, deep drifters, and current meter moorings." Richardson has been studying the general circulation of the Atlantic for more than a decade. The cruises have taken him along the Gulf Stream, the eastern Atlantic, and to the equatorial Atlantic. Currently an associate scientist at Woods Hole Oceanographic Institution, he earned a Ph.D. in physical oceanography from the University of Rhode Island in 1974. Richardson is also interested in the historical aspects of oceanography, and he likes to poke around in various libraries and archives to find old maps. In the course of these excursions, Richardson discovered Benjamin Franklin's original chart of the Gulf Stream.

Theodore H. Fleming (page 52) became interested in fruit-eating bats while working in Panama on the Smithsonian Institution's Mammals of Panama Project in the late sixties. His early work dealt with reproductive cycles and food habits, but over the years he has become increasingly curious about how individual bats sustain themselves. Fleming is currently writing a book that summarizes his past ten years of research at Santa Rosa National Park in Costa Rica. It focuses on the behavioral ecology of the short-tailed fruit bat in tropical dry forest and the bat's impact on ecological succession. The forty-three-year-old biology professor is temporarily working at Duke University while on leave from the University of Miami. He spends his spare hours tending to his garden and helping his wife raise two children.



To get to the place where she does her research, **Linda A. Deegan** (page 60) has to drive three hours from Baton Rouge to Morgan City, Louisiana, then rent a motorboat and pilot it another hour to the mouth of the Atchafalaya River.

Since her study site—which will be the home of the Mississippi River's next delta—is so remote, she usually camps out there for a few days at a time. Undue hardships? Deegan doesn't look at it that way. "You just have to be self-sufficient," she says. "If you go down there and forget something, you're sunk." Most researchers in Louisiana State University's coastal ecology unit have made the same adjustment. For thirty-five years, dozens of them have shuttled back and forth to the delta, in a series of projects designed to cover all aspects of the new ecosystem. Some are geomorphologists—"they're the ones who get to name the new delta islands after themselves," Deegan says—others work on vegetation or fish. Deegan, who has studied habitat use by the fish populations in the delta, will start this fall as an assistant professor at the University of Massachusetts, Amherst. Coauthor **Christopher Neill** is a research associate with the coastal ecology program. Neill specializes in coastal marshes, but his emphasis is on management. "We are trying to reduce the environmental impact on the marshes caused by the oil and gas indus-



tries," he says. "Basically, we're looking for ways to restore what's been lost as a result of dredging for canals." Louisiana has the highest rate of land loss in the nation, and one reason, Neill points out, is the lack of concern shown for wetlands.

Working with another professional photographer—in this case a wife—"you get a lot more done," says **Erwin Bauer** (page 94). He and **Peggy Bauer** do stay rather busy. This year, for example, the Bauers have two books coming out—*Photographing Wild Texas* (University of Texas Press) and *Erwin Bauer's Bears in Their World* (Outdoor Life Books). Now, they are on to a work about Africa. The two of them worry less and less about magazine assignments, Erwin says, "because more and more editors are taking pictures from stock houses." So, if they see something that looks promising, like the harbor seals they saw last year on the California coast, they just shoot it and assume it will pay off later. The Bauers were working with 300- and 400-millimeter lenses when they photographed the harbor seal in this month's "The Natural Moment."

DODGE CARAVAN. IT HAS NO EQUAL.

A PROVEN SUCCESS

Dodge Caravan. In its first year, it created a transportation revolution ...and sold out its entire production. It's a success that's easily explained. Caravan is one vehicle that can take the place of a luxury car, an economy car, a station wagon *and* a van.

THE RIGHT SIZE FOR 125 CUBIC FEET OF CARGO...OR 8 ADULTS

Caravan will seat two and hold 125 cubic feet of cargo. Or it can seat five—in fact, our versatile seating options allow room for up to eight. This year, there's even an optional convert-a-bed that sleep two. Yet, for all this interior room, Caravan's exterior length makes it easier to maneuver and park than a conventional station wagon.

And at just 5'4" it's no taller than the average American woman, which makes Caravan equally easy to step in or out of—to slip into your garage. Easier, in fact, than any full-sized van.

Anatomy of a Sting

A federal undercover operation may have shut down the black market in falcons, but not without ruffling some feathers

by Jim Robbins

On December 17, 1982, light snow lay on the ground at the Great Falls, Montana, airport. Though the air was cold, the sun, low in the winter sky, shone brightly. Sometime that day, two young brothers from West Germany carried several large boxes across the tarmac and loaded them onto a chartered Falcon jet. They climbed aboard and in a few minutes were airborne. Their destination was Washington, D.C., and their illicit cargo was alive—three gyrfalcons, prized by falconers throughout the world for their speed and superb hunting ability, and three prairie falcons, also used in falconry. All had been captured on the Montana prairie.

Later, after landing at Dulles International Airport, Marcus Ciesielski, then nineteen, and Lothar Ciesielski, then twenty-two, turned over the boxes to a man named François Messouadene. He in turn loaded them into the trunk of a black limousine; then Messouadene and the birds were driven 240 miles to Kennedy International Airport in New York. There, law-enforcement officials say, Messouadene purchased seven first-class tickets on Saudi Arabian Airlines—presumably one for each bird and one for himself—for a flight to Riyadh, the Saudi capital.

All three men are described by federal wildlife agents as members of a worldwide smuggling ring that deals in birds of prey. The limousine driver later told investigators that Messouadene had boasted the birds were going to members of the Saudi Arabian royal family. The Saudis were reportedly paying up to $100,000 a piece for healthy year-old gyrfalcons.

The taking of those six falcons from the wild, their sale to the Ciesielskis, and the events of December 17 were all carefully engineered and monitored by the U.S. Fish and Wildlife Service, as part of a three-year undercover investigation known as Operation Falcon. In this investigation, government agents temporarily entered the black market in raptors, staying in it long enough to find out the identities of the major nest robbers and their customers, and the scope of the activity.

By June 1984, officials apparently felt they had learned enough: 150 law-enforcement officers arrested 39 people and searched dozens more as the first phase of Operation Falcon ended. Marcus Ciesielski was arrested and pleaded guilty; his older brother and Messouadene escaped.

The Arabian connection is only one part of an international black market in birds of prey. This market, the Fish and Wildlife Service and some defendants say, reaches into exotic corners of the world and involves enormous sums of money. Most birds were being bought and sold for use by falconers, although some were traded for breeding purposes.

Some of the other major players who surfaced during Operation Falcon were connected with a Canadian company called Birds of Prey International, which claimed to have sold $750,000 worth of raptors over a two-year period—to the Saudis, among others.

More than thirty Americans in fourteen states were also arrested. Primarily individual falconers—most without previous arrests—they either bought federally protected birds of prey from an undercover informant or manipulated leg bands to make it appear as if birds they had taken illegally from the wild were actually bred in captivity. Agents also claim that some falconers were establishing bogus captive-breeding projects so they could sell some of these "laundered" birds. While it is legal to trap some birds of prey for personal use, it is against federal law to buy or sell birds caught in the wild or to transport them across state lines. Birds bred in captivity can be legally traded.

At the center of Operation Falcon is federal informant John Jeffrey McPartlin, a controversial figure who for three years played the role of an underground dealer in birds of prey. Working with federal agents, McPartlin enticed falconers and traders to buy highly prized raptors that would have been difficult, if not impossible, to come by legally. Many he had trapped or purchased himself. During the course of the investigation McPartlin made more than 1,000 tapes and kept a daily log of his contacts with suspects, which now form the linchpin of the government's case.

But the government's techniques, especially the trapping of wild birds, have drawn the embittered fire of members of the North American Falconers Association (NAFA), some twenty of whom were arrested during Operation Falcon. Spokesmen for the organization claim the government did more harm than good, creating a much more widespread black market than existed before the operation and hurting falcon populations more seriously than individuals have ever done. And, as in the celebrated case of John DeLorean, they and others have criticized the use of the sting as a law-enforcement tactic. "They're like the devil," said Williston Shor, a publicist for the 1,400-member falconers association. "They entice you to do something and then they punish you for it. I'm ashamed to say it was my government."

There are other critics of the investigation, including officials of the Peregrine Fund, an eminent raptor-breeding facility based at Cornell University. But during

THE STATUE OF LIBERTY

PEWTER SCULPTURE

Fully clad in copper from the actual Statue of Liberty

he Danbury Mint is proud to offer a magnificent pewter sculp-re of the Statue of Liberty, entirely clad in copper from the tual Statue in New York harbor! *Indeed, a collectible of such eaning, beauty and interest may never come your way again.*

Commemorating the 100th anniversary of the world's most famous symbol of freedom and liberty

1886, President Grover Cleveland dedicated the Statue of Liber-, a gift from France honoring our democratic traditions. Today, the tatue of Liberty is being restored. In 1986, her centennial, she will e rededicated. The Danbury Mint is offering this beautiful sculp-re in honor of this historic occasion.

Fully clad in copper from the actual Statue of Liberty

s the Statue of Liberty is refurbished, some of the copper must be emoved. This has been made available to the Danbury Mint, and is eing incorporated into each sculpture. Each will be fully clad in opper which until very recently was part of the Statue of Liberty in lew York harbor! Moreover, the copper will be finished to replicate he weathered green patina of the venerable Lady.

Handcrafted with precision in American pewter

ach sculpture is meticulously crafted from rich American pewter, nsurpassed in its dignity. No other metal could have imparted to his sculpture the same noble bearing and stateliness.

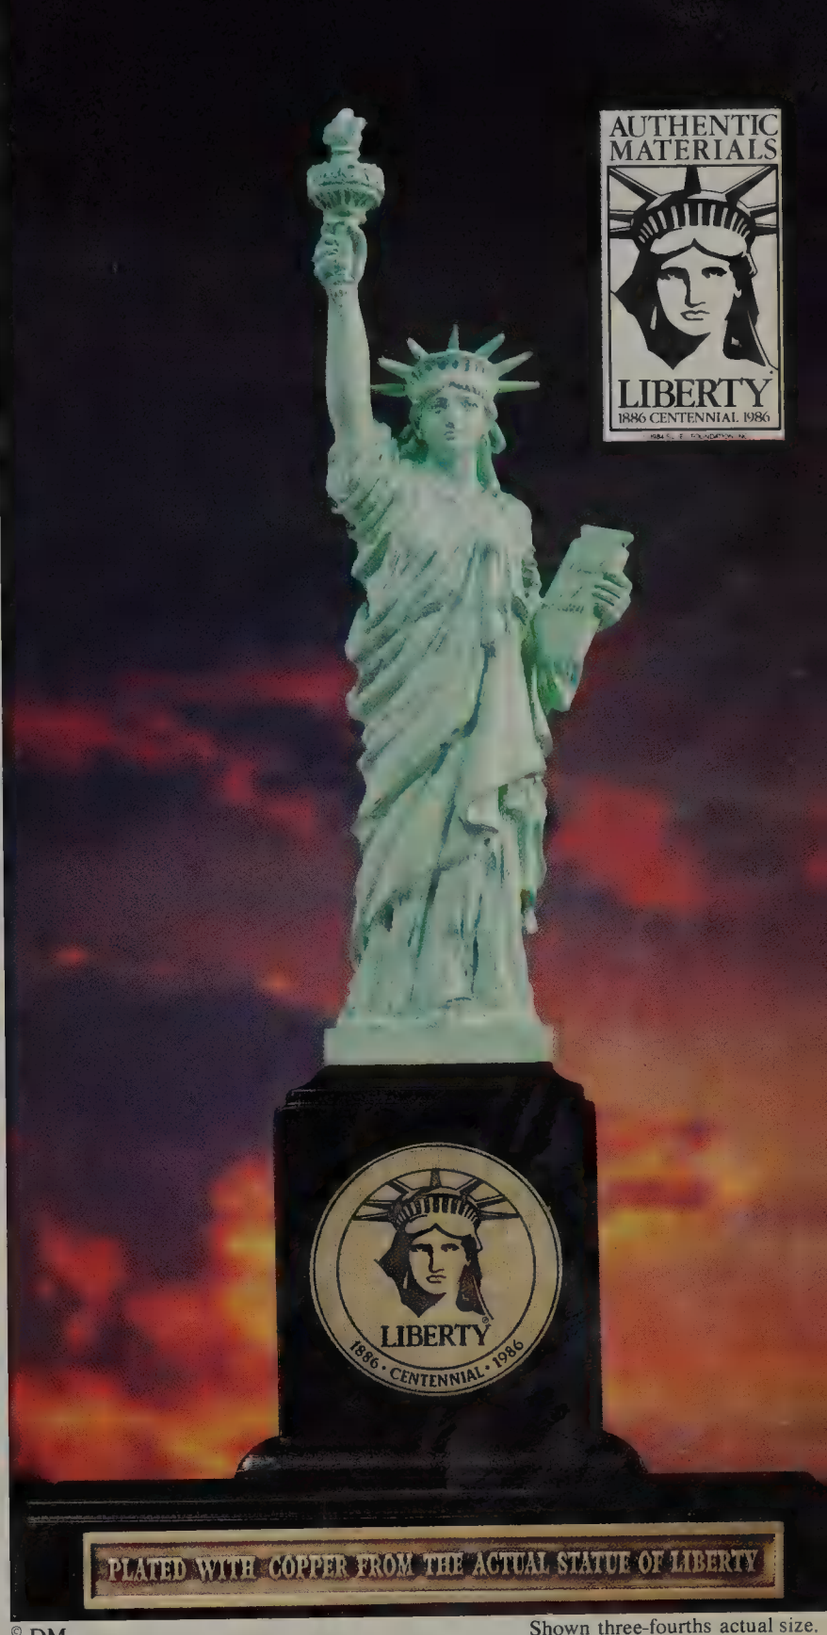
Your purchase contributes to the Statue of Liberty's restoration

ou'll be pleased to know that a percentage of the sculpture's pur-hase price will be contributed to the Statue of Liberty — Ellis Island oundation, Inc. Consequently, your purchase contributes to the tatue of Liberty's restoration. Accompanying your sculpture will e a Certificate of Authentic Materials, signed by Lee A. Iacocca, he Foundation's chairman.

A meaningful and unique heirloom

he original issue price of *The Statue f Liberty Pewter Sculpture* — com-lete with hardwood pedestal — is 150. This is an exceptional value vhen you consider that its authentic opper could make it irreplaceable in he years to come.

You will always be remembered or bringing this magnificent heirloom nto your family. Don't miss this once n a lifetime opportunity, send in your eservation today!



© DM

Shown three-fourths actual size.

THE STATUE OF LIBERTY PEWTER SCULPTURE

Please return by September 30, 1985.

Please accept my reservation for *The Statue of Liberty Pewter Sculpture*, a pewter sculpture of the Statue of Liberty, clad in copper from the actual Statue. The sculpture comes with a hardwood pedestal at no extra charge.

I need send no money now. I will pay for the sculpture in four convenient monthly installments of $37.50 each, the first being billed before shipment of my sculpture. If I am not satisfied, I may return my sculpture within thirty days for a replacement or refund.

taped conversations some defendants repeatedly named the Fund as a supplier of illegal birds. Fund officials have adamantly denied the allegations.

Operation Falcon has also received high praise—from wildlife groups that believe widespread aerie robbing was having a severe effect on rare and endangered raptor populations."Operation Falcon uncovered a substantial black market in birds of prey," said Jim Leape, an attorney for the National Audubon Society. "It revealed the need for much stricter regulation of people who take these birds for private use."

Whether Operation Falcon ultimately benefited the species of birds involved is as crucial a question as it is difficult to answer. The total number of birds caught and traded as part of the operation has not been made public, and estimates are still partly guesswork. Officials knew, either directly or indirectly, of 400 to 500 birds traded illegally during Operation Falcon, but they believe that could have represented as little as 10 percent of the actual trade.

Traditionally, falconry uses painstakingly trained birds of prey, which are carried on a gloved hand. Leather straps called jesses are attached to the bird's legs, and a hood is placed over its head. When prey is spotted, either on the ground or in the air, the legs are untethered, the hood removed, and the bird sent heavenward. Historically, raptors have often symbolized a higher spiritual level. Today birds of prey more often seem to stand for elegance and unbridled freedom.

In the Middle East, a cult of prestige currently surrounds certain kinds of birds, particularly long-winged gyrfalcons, because they are big (weighing up to four and a half pounds), fast flyers (possibly up to 200 miles per hour when diving for prey), and as arctic birds, very exotic.

One hundred to 150 nesting pairs of peregrines remain in the continental United States, while there are much larger numbers in Canada. Rough guesses peg the population of arctic gyrfalcons at 4,000 to 5,000 birds, spread throughout Alaska, Canada, and Greenland.

Operation Falcon is officially only three years old, but the idea of a wildlife sting dates back to the mid-1970s, when the Fish and Wildlife Service began trying a new strategy for conserving rare animals. Officials realized then that they were up against a more sophisticated breed of American poacher, who looked upon poaching as a business. The problem was no longer a few people killing deer in the off-season. Trophy bighorn sheep, for example, often taken out of season or from a

George Schaller; Bruce Coleman, Inc.

The $30,000 bird: Young gyrfalcons are prized by Saudi falconers.

national park, are worth up to $20,000, while elk antlers can sell for up to $100 a pound in the Oriental aphrodisiac market. The people dealing in these markets were more efficient than previous generations of poachers, and they operated in organized gangs. The man in a green uniform with a badge, who patrolled forests and fields, could not begin to cope with these rings. In response, the Fish and Wildlife Service formed a Special Operations branch to do undercover work.

When it was begun in 1981, Operation Falcon was one of the largest and most complex cases ever taken on by the new wildlife unit. Donald Schmidt, a former wildlife inspector, was appointed case agent. He conducted the investigation and, helped by others, oversaw Jeffrey McPartlin's education in sting techniques.

McPartlin was no stranger to falconry, or even to illicit dealings in rare birds, having been convicted in 1972 of conspiring to smuggle two gray gyrfalcons out of the country. Several years after the federal misdemeanor conviction, McPartlin, motivated by what he says was a concern about the increased trafficking in raptors, became an unpaid informant for the government. Heavyset, with thinning brown hair and a deep, authoritative voice, the 39-year-old falconer turned informant was a consummate actor during Operation Falcon. His reputation for being able to supply good birds spread throughout the small world of falconry. For three years he convinced dozens of people that he was an outlaw.

After months of selling on a small scale to falconers in the west, McPartlin received a letter from a young man named Lothar Ciesielski, of Cologne, West Germany. "I heard from my falconer friends in Nevada and California that you hav experience with falcons," Ciesielski wrot in his letter. "Maybe I will come to Cal fornia in the next months to visit m friends; by this opportunity I would like t visit you in Montana and exchange som experiences with falcons. I also have som interesting ideas and suggestions I woul like to talk about."

McPartlin responded with a friendl letter and an invitation for Lothar to visi Although agents knew little about th West German, he was their first interna tional contact. The Fish and Wildlife Se vice did not know then what it claims t know now: that the Ciesielski family—fa ther Konrad, mother Dorothea, and th two boys, Marcus and Lothar—ran one o the largest raptor smuggling operations i the world.

Konrad Ciesielski is a short, slightl overweight man in his fifties, who ostensi bly owns an insulating business. Lotha told agents his father has several busi nesses that he uses to hide income fron falcon smuggling. Officials claim the fam ily controls a network of falcon smuggler who take the birds from nests all over th world, including Iceland, the British Isles Canada, Scandinavia, and the Unite States. The Ciesielskis then peddle then to wealthy falconers in the Middle East.

McPartlin also noted in his diary tha Lothar complained that gyrfalcons hac become "too valuable."

"He said that people will now conside murdering each other if they should sho up simultaneously at a gyrfalcon aerie," McPartlin wrote in an entry dated Janu ary 25, 1984.

Lothar arrived in Great Falls on Octo ber 5, 1982. McPartlin, along with a spe cial agent, met the young German and in

The quick and easy way to learn a foreign language!

Based on the U.S. Military "Speed-up" Method of Language Learning.

Programmed for Rapid Learning!

It's been scientifically proven that we remember words we *hear* better than words we *see.* That's why you'll find the two audiocassettes in each Language / 30 package more useful than all the language books money can buy. Just start listening to the tapes, repeat the foreign phrases a few times and, believe it or not, you'll begin speaking like a native. It's that simple!

Remember, Language / 30 is a learning tool that *works.* It incorporates the "speed-up" method of language learning—the same method used to train U.S. government personnel who work overseas.

With Language / 30, you can practice your target language anytime, anywhere. You won't have to set aside hours just for language study. You can listen to Language / 30 while you're getting dressed, eating, driving to work, or even jogging. Whether you're studying French, Russian, Swahili, or any of the other 23 languages listed below, you'll improve your speaking fluency and listening comprehension *each time* you play the Language / 30 tapes.

Each program comes with two 45-minute cassettes, convenient phrase dictionary, in a compact, 6″×7″ waterproof vinyl case.

Introduced by Language Expert Charles Berlitz.

Each Language / 30 program features native voices speaking the most important and commonly used conversational phrases. You'll learn all the words you need to know for greetings, introductions, requests, and general conversations in hotels, restaurants, stores, theaters, and other places. And each cassette is introduced by world-renowned linguist Charles Berlitz, who explains the social customs and etiquette of the country.

So, whether you're going abroad for a short trip or an extended stay, you'll find that the fluency you've gained from Language / 30 will make your visit easier, more pleasant, and more enriching. Instead of being a "stranger in a strange land," you'll be able to converse freely with the natives in their own language.

Which of these 26 languages would you like to speak?

Offer good only in continental U.S.A.

vited him to his home. All conversations, which centered on the type and number of birds McPartlin could provide, were recorded with a body recorder. In his diary McPartlin said Lothar preferred passage females. Passage birds are those on their first migration south; they can fly and hunt but are easier to train than older birds. Lothar offered McPartlin $4,000 a bird "and says I cannot trap too many to meet his needs," McPartlin wrote.

There is a good deal of speculation, given Lothar's age and involvement in a global, jet-setting smuggling ring involving perhaps millions of dollars, that he may have been "puffing," or truth stretching, during the clandestine taping sessions—it's difficult to know for sure. Lothar even claimed that, through a relative of a former Mexican president, he had a permit to take forty falcons out of Mexico. And he claimed to have trapped peregrine falcons in Texas, smuggled them to Mexico, and shipped them from there, under the same permit.

Before the law-enforcement net would be cast in June, Marcus and Lothar Ciesielski would make roughly half a dozen trips to Great Falls to purchase thirty-six gyrfalcons that McPartlin had trapped. They also bought prairie falcons and peregrine falcons. The price of the venerated gyrs would eventually rise to $7,000 each, and the Ciesielskis would do more than $100,000 in business with the informant. These birds were shipped primarily to customers in the Middle East, as well as to falconers in Europe.

During their repeated visits to Montana, the young German brothers would reveal a host of details about their smuggling operation. For example, Lothar said that his mother had once smuggled raptor eggs out of the United States by painting them to look like Easter eggs. Lothar also recounted how his girlfriend had carried eggs through U.S. Customs in a vinyl cosmetics case.

Although McPartlin himself trapped most of the birds sold to the Ciesielskis, he also bought several gyrs from Birds of Prey International (BPI), which specialized in smuggling birds stolen from nests in Northwest Canada. Most of the birds sold by this company went to an overseas market, allegedly including, once again, the royal family of Saudi Arabia.

Glen Luckman, a dapper young Canadian with an Errol Flynn mustache, was McPartlin's initial contact with BPI. In May of 1983 Luckman visited McPartlin in Great Falls. After viewing three gyrfalcons McPartlin had for sale, Luckman told him he could sell the birds in Arabia for $25,000 to $30,000 each, while a white female gyrfalcon could fetch $100,000. He said his going purchase price was $5,000 to $8,000 apiece.

Luckman told McPartlin he needed to take the birds to his partner, John Slaytor, in Ontario. After inspecting the birds, Slaytor offered McPartlin $10,000 plus a peregrine falcon for the three gyrs.

In October of 1983 Luckman told McPartlin that he and his confederates had amassed an impressive stock of raptors: they had removed twenty-four nestling gyrfalcons and fifteen baby peregrines from their nests. They also had twelve eyass, or baby Finnish goshawks, that Luckman had smuggled into Canada from Finland.

McPartlin told Luckman he could sell the gyrfalcons for $7,000 apiece; Luckman brought eight of the birds to Great Falls, and told McPartlin that he had smuggled the birds into the United States by driving his car under a fence at a remote border crossing. On a subsequent trip, he would crash his auto through a barbed wire fence that marked the international boundary.

But Luckman's good fortune eventually ran out. He was arrested by Canadian authorities in June, and pleaded guilty to two felony counts and two misdemeanor counts in U.S. District Court in Great Falls on November 15, 1984. He was fined $23,000. The plea was accepted by the government in exchange for information provided against his partner, John Slaytor. Hundreds of pages of information provided by Luckman led to the arrests of nineteen more people in Canada in late February.

What about the Saudis? What has their reaction been to two independent claims that they have illegally purchased a large number of rare and endangered falcons and used their diplomatic privileges to spirit the birds to the Middle East? Through a Washington attorney, they have quietly denied the accusations, saying the whole plot sounds like "bird feathers." They have not responded to specific charges and did not return phone calls.

Aside from the international conspirators, most of those caught in the domestic end of Operation Falcon to date are relatively small operators. They are primarily devout falconers who fly the birds for sport and who were apparently unable to resist the lure of falconry's most dramatic birds—peregrine falcons and gyrfalcons, two species almost impossible to obtain legally. Many of those arrested said McPartlin repeatedly called them with offers for birds, often repeatedly lowering the price if they refused. As one Texas attorney said, "It's like having someone bring Marilyn Monroe by and asking if she can spend the night."

Most of these small-timers were charged with felonies and allowed to plead guilty to misdemeanors—such crimes as transporting protected birds across state lines, possession of an endangered species, and manipulating federal raptor bands.

The laundering of birds, or "covering" them with paperwork to make them appear to be domestically bred, is difficult but not as complicated as actually breeding the birds. Raptors require very carefully controlled environments for mating and incubation, and the proper equipment is costly. Extra bands are easier to come by: bands from birds that die can be reused or breeders can claim to have raised more birds than they actually did and request additional bands.

By February all of the court cases stemming from Operation Falcon had been concluded, and all except two of the defendants pleaded or were found guilty.

But officials don't expect the criminal charges to end there. It is standard law-enforcement procedure to arrest the little guys, usually the least efficient lawbreakers and the easiest to apprehend, and then, by offering leniency in exchange for cooperation, gather evidence against the career criminal. As a result of these "rollovers" officials expect a second, and perhaps third, wave of arrests of thirty to forty suspects.

Meanwhile, however, the Fish and Wildlife Service has made other kinds of waves by directing its investigators toward the prestigious Peregrine Fund, which raises and releases captive peregrine falcons into the wild in hopes they will reestablish a natural population. The Fund, the world's largest breeder of raptors, has three breeding facilities—one at Cornell University in Ithaca, New York, one in Boise, Idaho, at the recently established World Center for Birds of Prey, and a third in Santa Cruz, California. Breeders at these three locations have already raised several hundred birds and released them into the wild. As a result, peregrine falcons are nesting again in New York City, Baltimore, and other parts of the east, as well as in places in the west from which they had disappeared.

Investigative reports on Lothar Ciesielski indicate that he repeatedly accused the Peregrine Fund of selling birds illegally, a charge investigators took seriously. In a letter to Thomas Cade, director of the Peregrine Fund, Harrison B. Tordoff, former president of the American Ornithologist's Union, described the inspection of a raptor-breeding facility owned by a friend. In addition to the in-

330399. Kiri Te Kanawa—Come To The Fair. Folk Songs *(Digital*—Angel)

332536. Kiri Te Kanawa—Songs of the Auvergne, Vol. 2. *Also* Villa-Lobos: Bachianas Brasileiras No. 5 *(Digital*—Angel)

333112. Andreas Vollenweider—White Winds. The inventive harpist's latest *(Digital*—CBS)

334763. John Williams—Bach, Handel, Marcello Concertos *arr. for guitar (Digital*—CBS Masterworks)

ANY 11 FOR $1.00

plus shipping and handling

if you join now and agree to buy 8 more selections (at regular Club prices) in the coming 3 years

Here's a wonderful opportunity to start or add to your collection of the world's greatest music—on easy-to-play, carefree tape cassettes! As a new member of the Columbia Classical Club, you can get any 11 cassettes for only $1.00, plus shipping and handling. *(Or you may take your 11 selections on stereo records.)* In exchange, you agree to buy just 8 more selections in the next three years, at regular Club prices (which currently are $7.98 to $9.98, plus shipping and handling; multi-unit sets and some digital recordings may be somewhat higher.)

How the Club works: every four weeks (13 times a year) you'll receive our Music Magazine. It describes the "Classical Selection of the Month" *plus* scores of classical releases, as well as selections from other fields of music. In addition, up to six times a year you may receive offers of Special Selections, usually at a discount off regular Club prices, for a total of up to 19 buying opportunities.

There is no obligation to accept the "Selection of the Month"—you order only the recordings you want *when you want them!* A special response card will be enclosed with each Magazine—mail it by the date specified to order or reject any selection. And if you want *only* the "Selection of the Month", do nothing—it will be shipped automatically. You'll have at least ten days in which to make your decision—if you ever have less time than that, just return the Selection at our expense. And you may cancel membership anytime after buying 8 selections, or continue under our money-saving bonus plan.

10-Day Free Trial: we'll send details of the Club's operation with your introductory shipment. If you are not satisfied for any reason, return everything within 10 days—your membership will be canceled and you will owe nothing.

Special Start-Your-Membership-Now Offer: you may *also* choose your first selection now—and we'll send it to you for at least 60% off regular Club prices (only $2.99). This discount purchase reduces your membership obligation immediately—you then need buy just 7 more (instead of 8) in 3 years. Just check box in application and fill in the number of your first selection.

NOTE: selections with two numbers are 2-record sets or double-length tapes. Each of these "double selections" counts as 2—so write in both numbers. © CBS Columbia House

COLUMBIA CLASSICAL CLUB, Columbia House, Terre Haute, IN 47811

Please accept my membership application under the terms outlined in this advertisement. Send me the 11 classical selections listed here for only $1.00, plus shipping and handling. I agree to buy eight more selections (at regular Club prices) in the coming three years—and may cancel membership at any time after doing so.

Send my selections in this type of recording (check one):
☐ TAPE CASSETTES ☐ STEREO RECORDS

☐ Mr. ☐ Mrs. ☐ Miss _____
Print First Name Initial Last Name

Address _____ Apt. _____

City _____

State _____ Zip _____

Do you have a telephone? (check one) ☐ Yes ☐ No 226/F85

Do you have a credit card? (check one) ☐ Yes ☐ No

This offer is not available in APO, FPO, Alaska, Hawaii, Puerto Rico; please write for details of alternative offer.

☐ **Also send my first selection for at least a 60% discount** for which I will be billed an additional $2.99. I then need buy only 7 more (instead of 8) at regular Club prices, in the coming three years.

All applications subject to review; Columbia House reserves the right to reject any application.

spection, Tordoff said, federal wildlife agents interrogated the breeder.

"I can't recall it word for word," Tordoff said of the questioning, "but the gist was that allegations had been made by unnamed persons against the Peregrine Fund, and therefore federal agents had a duty to investigate them." Among the points raised during questioning was the charge that the Fund had taken eggs and young of wild peregrines, had been selling birds to falconers in the Middle East, Europe, and the United States, and had been rewarding large donors to the Fund with falcons for their personal use.

Tom Cade believes the government has unreasonably damaged the Fund's reputation in the small circle of falcon breeders by asking virtually all of those arrested whether they knew about illegal activities by the Fund. "It leads the person who is being interrogated to believe that the Peregrine Fund engaged in illegal activities," Cade said. "They stem from allegations made about us from German traffickers. They're complete fabrications. [The Fish and Wildlife Service] found nothing because there is nothing to find. We've been under investigation for ten years. How long does an investigation have to go on before there's any evidence of wrongdoing?" In at least two cases, Cade said, he was denied funding because the Fund was "under suspicion." The government has refused to comment on this aspect of Operation Falcon because it is "an ongoing investigation."

Williston Shor, publicist for the falconers association, has fired off a litany of accusations against the Special Operations branch, in letters and press releases. Operation Falcon has given NAFA, which had twenty members arrested, a resplendent black eye and confirmed a public perception that falconers have fought for years—that they care little for preservation of the species but are primarily interested in owning birds. NAFA fears the arrests may bring a revocation of the 1983 regulations that allowed them to buy and sell captive raptors.

In fact, shortly after the arrests, the National Audubon Society and the National Wildlife Federation petitioned Secretary of the Interior William Clark to review the regulations, with an eye toward disallowing sales of birds bred in captivity. Both groups opposed the regulations when they were first proposed. However, Shor points out that falconers attempted to turn McPartlin in several times—evidence, he contends, that falconers keep their own ranks groomed. He also claims that McPartlin, by trapping thirty-six gyrfalcons, damaged a wild resource.

But the Audubon Society doesn't agree. According to Audubon Society spokesman Amos Eno, 400 to 500 birds were sold illegally during the three years of Operation Falcon. Only 40 to 50 of these were removed from the wild by McPartlin. "I think the service's use of the birds was conservative," says Eno.

Agents say that during the entire course of the investigation, the total number of peregrine falcons trapped or stolen from nests in the western United States for Operation Falcon was between 10 and 20. With 100 to 150 pairs of peregrines in the west, those numbers alone may not decimate the species. The impact, however, according to William Burnham, vice-president of the Peregrine Fund, manager of the World Center for Birds of Prey in Boise, and a leading expert on western peregrine populations, could be serious.

"It depends on where they were removed from," Burnham said. "We've found quite a few birds in Arizona and Utah that are reproducing fairly well. It's difficult to say if it would have a dramatic impact in these areas. On the other hand if you take the birds from Montana or Colorado it could harm the species. If you're dealing with an endangered species and remove ten to twenty birds it's certainly not going to do the population any good." According to government officials, most peregrines taken from the wild during Operation Falcon came from Arizona and Utah.

Entrapment has been one of the most constant complaints about Operation Falcon. "They entrapped people," said Ralph Rogers of Winifred, Montana, who is a regional director of NAFA. "Instead of packets of dope or bundles of money, they used a precious wild resource."

But Justice Department attorneys argue that sting tactics are a legitimate law-enforcement tool. Christopher Nuechterlein, who has prosecuted several Operation Falcon cases for the government, says a defendant can win on an entrapment plea only if he can prove he was intimidated into doing something he wouldn't otherwise have done. "The government provided an opportunity," he says. "It did not overpower their free will."

In November the entrapment argument was put to the test during the trial of three men from the Dallas area arrested during Operation Falcon: Dr. Greg Moore, a veterinarian, and Dr. James E. Doyle, a plastic surgeon, who were charged with buying and transporting peregrine falcons, an endangered species, and Burt Loessberg, charged with conspiracy to violate federal wildlife laws. Five defense attorneys claimed that the government's undercover informant, McPartlin, had befriended their clients and then led them into wrongdoing. They made a great deal of McPartlin's criminal record. They also accused McPartlin of luring as many people as possible into his web in order to hold on to his job, and its $2,200 a month salary, as long as possible.

The jury's decision was a confusing one. Moore was acquitted, the jury foreman reported, because he was entrapped; Loessberg was acquitted because of a lack of evidence. Doyle, however, was found guilty. "We felt he walked into it with his eyes wide open," said Dan Whitfield, the jury foreman.

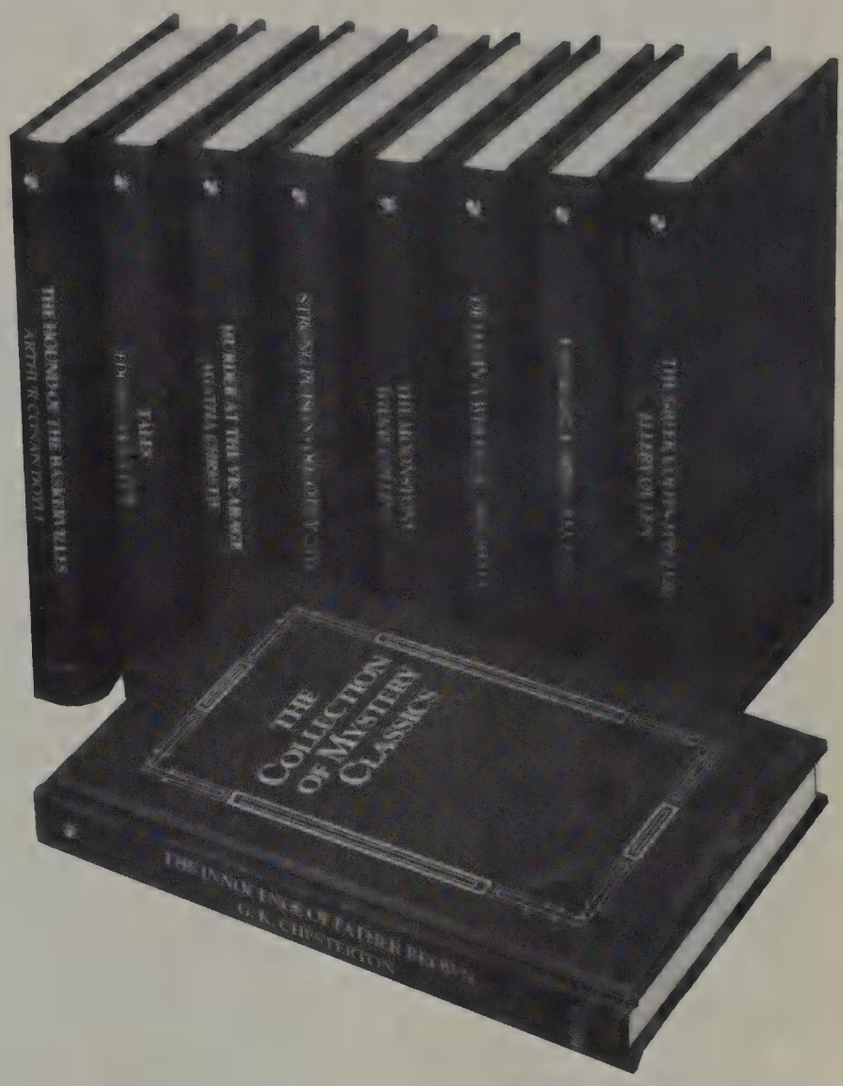
The undercover portion of Operation Falcon drew to a conclusion in the early morning hours of June 29, 1984. In motel rooms around the country, more than 150 law-enforcement officers gathered for the bust. At precisely the same time, in groups of six, seven, and eight, they descended on the falconers and breeders, aimed guns at their heads, and handcuffed them.

But there were several large holes in the tightening dragnet. Lothar Ciesielski, who had masterminded most of the smuggling in the United States, was indicted, but he was home in West Germany at the time, facing wildlife charges unrelated to Operation Falcon. Marcus Ciesielski was not so lucky; he had been convinced by McPartlin to travel to Montana to pick up some more gyrfalcons. He arrived in Calgary, Alberta, the night before the warrants were to expire, so the Fish and Wildlife Service sent a chartered plane to Canada to bring the youngest Ciesielski to the United States. After spending two months in jail awaiting trial, Marcus pleaded guilty to three misdemeanors. He was fined $10,000 and allowed to leave the country. In addition to Lothar, officials also missed François Messouadene.

It's extremely difficult to measure the impact of an investigation like Operation Falcon on the bird populations it was intended to protect. The Fish and Wildlife Service may have shut off the black market, both by arresting some of the principals and by demonstrating that wildlife crimes are being taken seriously. But as with drug trading, the operation may simply have forced illegal activity further underground—driving the prices higher and making the rewards of selling a wild falcon, or owning one, seem all the more worth the trouble. Its true effect will only become clearer in the months ahead.

Jim Robbins, a freelance writer based in Helena, Montana, writes about the Rocky Mountain region for the New York Times *and other publications.*

Get away with murder for FREE



Receive the greatest mysteries ever written FREE for 15 days.

Think of your favorite whodunits, most popular sleuths, best known mystery writers. They're all included in THE COLLECTION OF MYSTERY CLASSICS.

We asked a panel of mystery editors to select the best in every category. They came up with a list of classic suspense and detection novels you'll want to read and reread, save, share and enjoy, again and again. They're all intriguing tales of murder, cunning and crime:

THE HOUND OF THE BASKERVILLES, a spine-tingling Sherlock Holmes story by Sir Arthur Conan Doyle.

DEATH IN A WHITE TIE by Ngaio Marsh with urbane Roderick Alleyn of Scotland Yard.

TOO MANY COOKS, a bizarre murder mystery for Nero Wolfe to solve, by Rex Stout.

MURDER AT THE VICARAGE pits Miss Jane Marple's intuition against a cunning murderer, created by Agatha Christie.

Enjoy solving another mystery masterpiece every month. Each exclusive Dorset Edition volume is bound in rich, durable, burgundy-red padded leatherette, and goldstamped for added elegance. Its smythe-sewn pages and acid-free paper can withstand years of handling. Your beautifully bound mystery volumes, not available in any bookstore, will become collector's items for your family, a lasting home library.

Examine your first volume FREE for 15 days. If you're not completely satisfied, just return it and owe nothing. However, if you decide it's the perfect mystery in the perfect binding, just pay $9.95 plus postage and handling. Books of this quality usually sell for twice that amount.

Each month, thereafter, you'll receive another mystery classic on the same 15-day free-examination basis. There's no minimum number to purchase and you may cancel your subscription at any time.

Preview this exclusive new collection of handsomely bound mystery classics without risk or obligation. Mail this coupon today.

THE COLLECTION OF MYSTERY CLASSICS Bantam Books, Box 958, Hicksville, N.Y. 11802

YES, I want to get away with murder for FREE with THE COLLECTION OF MYSTERY CLASSICS. Please send me The Hound of the Baskervilles for a FREE 15-day examination. If I'm not delighted, I may return it and owe nothing. If I decide to keep the book, I will pay just $9.95 plus postage and handling. Then, each month, I will receive another mystery classic on the same fully returnable 15-day free-trial basis. There is no minimum number of books to buy and I may cancel my subscription at any time.

Here Goes Nothing

"But when nothing becomes something, the inherent power of evolution, normally an exquisitely conservative force, can break forth"

by Stephen Jay Gould

Goliath paid the highest of all prices to learn the most elementary of all lessons—thou shalt not judge intrinsic quality by external appearance. When the giant first saw David, "he disdained him; for he was but a youth, and ruddy, and of a fair contenance" (1 Sam. 17: 42). Saul had been similarly unimpressed when David presented himself as an opponent for Goliath and savior of Israel. Saul doubted out loud: "for thou art but a youth, and he a man of war from his youth" (1 Sam. 17: 33). But David persuaded Saul by telling him that actions speak louder than appearances—for David, as a young shepherd, had rescued a lamb from a predacious lion: "I went out after him, and smote him, and delivered it out of his mouth" (1 Sam. 17: 35).

This old tale presents a double-entendre to introduce this column. It serves first as a preface to my opening story about a famous insight deceptively clothed in drab appearance—and second as a quirky lead to the body of this essay, a tale of animals that really do deliver from their mouths: *Rheobatrachus silus,* an Australian frog that swallows its fertilized eggs, broods tadpoles in its stomach, and gives birth to young frogs through its mouth.

Henry Walter Bates landed at Pará (now Belém), Brazil, near the mouth of the Amazon, in 1848. He arrived with Alfred Russel Wallace, who had suggested the trip to tropical jungles, arguing that a direct study of nature at her richest might elucidate the origin of species and also provide many fine specimens for sale. Wallace returned to England in 1852, but Bates remained for eleven years, collecting nearly 8,000 new species (mostly insects) and exploring the entire Amazon valley.

In 1863, Bates published his two-volume classic, perhaps the greatest work of nineteenth-century natural history and travel, *The Naturalist on the River Amazons.* But two years earlier, Bates had hidden his most exciting discovery in a technical paper with a disarmingly pedestrian title: "Contributions to an Insect Fauna of the Amazon Valley," published in the *Transactions of the Linnaean Society.* The reviewer of Bates's paper (*Natural History Reviews,* 1863, pp. 219–24) lauded Bates's insight but lamented the ill-chosen label: "From its unpretending and somewhat indefinite title," he wrote, "we fear [that Bates's work] may be overlooked in the ever-flowing rush of scientific literature." The reviewer therefore sought to rescue Bates from his own modesty by providing a bit of publicity for the discovery. Fortunately, he had sufficient oomph to give Bates a good send-off. The reviewer was Charles Darwin, and he added a section on Bates's insight to the last edition of the *Origin of Species.*

Bates had discovered and correctly explained the major style of protective mimicry in animals. In Batesian mimicry (as we still call it today), uncommon and tasty animals (the mimics) gain protection by evolving uncanny resemblance to abundant and foul-tasting creatures (the models) that predators learn to avoid. The viceroy butterfly is a dead ringer for the monarch, which, as a caterpillar, consumes enough noxious poisons from its favored plant foods to sicken any untutored bird. (Vomiting birds have become a cliché of natural history films. Once afflicted, twice shy, as the old saying goes. The tale may be more than twice told, but many cognoscenti do not realize that the viceroy's name memorializes its mimicry—for this butterfly is the surrogate, or vice-king, to the ruler, or monarch, itself.)

Darwin delighted in Bates's discovery because he viewed mimicry as such a fine demonstration of evolution in action. Creationism, Darwin consistently argued, cannot be disproved directly because it claims to explain everything. Creationism becomes impervious to test and, therefore, useless to science. Evolutionists must proceed by showing that any creationist explanation becomes a *reductio ad absurdum* by twists of illogic and special pleading required to preserve the idea of God's unalterable will in the face of evidence for historical change.

In his review of Bates's paper, Darwin emphasizes that creationists must explain the precision of duplicity by mimics as a simple act of divine construction—"they were thus clothed from the hour of their creation," he writes. Such a claim, Darwin then argues, is even worse than wrong because it stymies science by providing no possible test for truth or falsity—it is an argument "made at the expense of putting an effectual bar to all further inquiry." Darwin then presents his *reductio ad absurdum,* showing that any fair-minded person must view mimicry as a product of historical change.

Creationists had made a central distinction between true species, or entities created by God, and mere varieties, or products of small changes permitted within a created type (breeds of dogs or strains of wheat, for example). But Bates had shown that some mimics are true species and others only varieties of species that lack mimetic features in regions not inhabited by the model. Would God have created some mimics from the dust of the earth but allowed others to reach their precision by

Stoves Unequaled In Design.

Chances are, if you are considering a stove, you are approaching its purchase in a serious manner. Gone are the days when all stoves were assumed to be equal. Educated consumers know they are not, and that the differences from one brand to the next can be substantial. This is so because some wood stoves have been undergoing a quiet revolution in function, a revolution masked by the constant nature of the outer forms.

Extraordinary Features

No stoves more reflect this revolution than Consolidated Dutchwest's Federal Airtights. These stoves include a combination of features which just a decade ago would have been impossible to imagine. Today our 100% cast-iron stoves and inserts burn wood and coal and convert from one fuel to the other in a few moments. Depending on size, they hold wood fires from 6 to 14 hours while squeezing as much as three quarters of the potential heat from each log. They vent from the top and back and install freestanding or as fireplace inserts. Front and side door loading, convection systems, fans, ceramic windows, shaker grates, ashdrawers, and polished cooktops are standard features. As well, we reengineered each stove and insert for catalytic operation. Why? Because with a catalytic combustor, airtight operating efficiency can approach 80% while reducing creosote build-up and smoke pollution up to 90%.

Federal Period Styling

While concentrating on function, we haven't compromised on appearance. We've employed the simple clear lines of Federal period architecture (1810-1830), as elegant today as they were then, to create a unique and beautiful pattern of raised lines and arches. Our distinctive pebble finish and solid brass trim highlight the classic styling. We know our stoves will frequently be sited in living rooms and we've gone to great lengths to assure they belong there. Those of you who eventually own a Consolidated Dutchwest stove will find our trademark pebble finish is not only beautiful, but also increases our stoves' radiant surfaces by a third. Even while stressing appearance we never forget performance.

Free Corning Catalytic Combustor

This Fall Save $80.00.

Since the emergence of the airtight stove as the woodstove industry's best product, there's been belated but growing awareness of the downside of airtight woodburning—creosote buildup and pollution—problems caused by the lower firing temperatures of controlled combustion. Technology's answer is the inclusion of a catalytic combustor in each airtight stove. The 'combustor' reduces the temperature at which woodsmoke burns from 1,200 degrees F to under 500 degrees F. The result is an almost complete burn, a big boost in operating efficiency, and major reductions in creosote buildup and pollution. In short—a great idea that works. Each Federal Airtight is designed to accept a catalytic combustor in the secondary combustion chamber. This fall we'll provide a Corning Catalytic Combustor free with each stove and insert purchased. Offer expires November 26, 1985.

limited natural selection within the confines of a created type? Is it not more reasonable to propose that mimicking species began as varieties and then evolved further to become separate entities? And much worse for creationists: Bates had shown that some mimicking species resemble models that are only varieties. Would God have created a mimic from scratch to resemble another form that evolved (in strictly limited fashion) to its current state? God may work in strange ways, his wonders to perform—but would he really so tax our credulity? The historical explanation makes so much more sense.

But if mimicry became a source of delight for Darwin, it also presented a serious problem. We may easily grasp the necessity for a historical account. We may understand *how* the system works once all its elements develop, but *why* does this process of mimicry ever begin? What starts it off, and what propels it forward? Why, in Darwin's words, "to the perplexity of naturalists, has nature condescended to the tricks of the stage?" More specifically: any butterfly mimic, in the rich faunas of the Amazon valley, shares its space with many potential models. Why does a mimic converge upon one particular model? We can understand how natural selection might perfect a resemblance already well established, but what begins the process along one of many potential pathways—especially since we can scarcely imagine that a 1 or 2 percent resemblance to a model provides much, if any, advantage for a mimic. This old dilemma in evolutionary theory even has a name in the jargon of my profession—the problem of the "incipient stages of useful structures." Darwin had a good answer for mimicry, and I will return to it after a long story about frogs—the central subject of this essay and another illustration of the same principle that Darwin established to resolve the dilemma of incipient stages.

We remember Darwin's *Beagle* voyage primarily for the big and spectacular animals that he discovered or studied: the fossil *Toxodon* and the giant Galápagos tortoises. But many small creatures, though less celebrated, brought enormous scientific reward—among them a Chilean frog appropriately named *Rhinoderma darwini*. Most frogs lay their eggs in water and then allow the tadpoles to make their own way, but many species have evolved various styles of parental care, and the range of these adaptations extols nature's unity in diversity.

In *R. darwini*, males ingest the fertilized eggs and brood them in the large throat pouches usually reserved for an earlier act of courtship—the incessant croaking that defines territory and attracts females. Up to fifteen young may fill the pouch, puffing out all along the father's ventral (lower) surface and compressing the vital organs above. G.B. Howes ended his classical account of this curious life style (*Proceedings of the Zoological Society of London*, 1888) with a charming anthropomorphism. Previous students of *Rhinoderma*, he noted, had supposed that the male does not feed while carrying his young. But Howes dissected a brooding male and found its stomach full of beetles and flies and its large intestine clogged with "excreta like that of a normal individual." He concluded, with an almost palpable sigh of relief, "that this extraordinary paternal instinct does not lead up to that self-abnegation" postulated by previous authors.

But nature consistently frustrates our attempts to read intrinsic solicitude into her ways. In November 1973, two Australian scientists discovered a form of parental care that must preclude feeding, for these frogs brood their young in their stomachs and then give birth through their mouths. And we can scarcely imagine that a single organ acts as a nurturing uterus and a site of acid digestion at the same time.

Rheobatrachus silus, a small aquatic frog living under stones or in rock pools of shallow streams and rills in a small area of southeast Queensland, was first discovered and described in 1973. Later that year, C.J. Corben and G.J. Ingram of Brisbane attempted to transfer a specimen from one aquarium to another. To their astonishment, it "rose to the surface of the water and, after compression of the lateral body muscles, propulsively ejected from the mouth six living tadpoles" (from the original description published by Corben, Ingram, and M.J. Tyler in *Science*, vol. 186, 1974, p. 946). They initially assumed, from their knowledge of *Rhinoderma*, that their brooder was a male rearing young in its throat pouch. Eighteen days later, they found a young frog swimming beside its parent; two days later, a further pair emerged unobserved in the night. At that point, they decided (as the euphemism goes) to "sacrifice" their golden goose. But the parent, when grasped, "ejected by propulsive vomiting eight juveniles in the space of no more than two seconds. Over the next few minutes a further five juveniles were ejected." They then dissected the parent and received their biggest surprise. The frog had no vocal sac. It was a female with "a very large, thin-walled, dilated stomach"—the obvious home of the next generation.

Natural birth had not yet been observed in *Rheobatrachus*. All young had either emerged unobserved or been vomited forth as a violent reaction after handling. The first young had greeted the outside world prematurely as tadpoles (since development clearly proceeds all the way to froghood in the mother's stomach, as later births demonstrated).

Art then frustrated nature, and a second observation also failed to resolve the mode of natural birth. In January 1978, a pregnant female was shipped express airfreight from Brisbane to Adelaide for observation. But the poor frog was—yes, you guessed it—"delayed" by an industrial dispute. The mother, still hanging on, arrived surrounded by twenty-one dead young; a twenty-second frog remained in her stomach upon dissection. Finally, in 1979, K.R. McDonald and D.B. Carter successfully transported two pregnant females to Adelaide—and the great event was finally recorded. The first female, carefully set up for photography, frustrated all hopes by vomiting six juveniles "at great speed, flying upwards . . . for approximately one meter . . . a substantial distance relative to the body size of the female." But the second mother obliged. Of her twenty-seven offspring, two appeared gently and, apparently, voluntarily. The mother "partially emerged from the water, shook her head, opened her mouth and two babies actively struggled out." The photo of a fully formed baby frog, resting on its parent's tongue before birth, has already become a classic of natural history. This second female, about two inches long, weighed 11.62 grams after birth. Her twenty-six children weighed 7.66 grams, or 66 percent of her weight without them. An admirable effort indeed!

The New England Collectors Society Presents
An *Exclusive* First Edition

The First Beatrix Potter® Silverplated Sculpted Spoon "Peter Rabbit"®

ACTUAL SIZE OF SPOON 4 7/8"

"Peter Rabbit" ®

© F. Warne & Co., New York & London, 1983

Created by

Reed & Barton Silversmiths

- **Richly detailed, fully dimensional original sculpture forms handle.**
- **Luxuriously silverplated; hallmarked and registered.**
- **Individually crafted by world famous Reed & Barton Silversmiths.**
- **Not sold in stores.**
- **Priced at only $14.50.**

The sculpted spoon is the most prized of all collector's spoons and now, for the first time ever, the New England Collectors Society is issuing the first silverplated sculpted spoon, "Peter Rabbit",® as the first spoon in the Beatrix Potter® Silverplated Sculpted Spoon Collection.

Each lavishly silverplated "Peter Rabbit"® spoon is individually created by world famous Reed & Barton Silversmiths to their renowned high standards. The sculpted handle is intricately detailed and radiates the delightful vitality of the original Potter® art.

Every spoon is individually hallmarked and registered. Each subscriber will receive a Certificate of Registration attesting to the spoon's authenticity and First Edition status.

"Peter Rabbit"® is the perfect beginning or addition to any collection and it's an ideal gift . . . available exclusively from the New England Collectors Society.

The New England Collectors Society is a subsidiary of Reed & Barton Silversmiths, makers of fine products since 1824.

NE **The New England Collectors Society**

Rheobatrachus inspired great excitement among Australian scientists, and research groups in Adelaide and Brisbane have been studying this frog intensively, with all work admirably summarized and discussed in a volume edited by M.J. Tyler (*The Gastric Brooding Frog,* Croom Helm, London and Canberra, 1983). Rarely has such extensive and coordinated information been presented on a natural oddity, and we are grateful to these Australian scientists for bringing together their work in such a useful way.

This volume also presents enough detail (usually lacking in technical publications) to give nonscientists a feel for the actual procedures of research, warts and all (an appropriate metaphor for the subject). Glen Ingram's article on natural history, for example, enumerates all the day-to-day dilemmas that technical papers rarely mention: slippery bodies that elude capture; simple difficulties in seeing a small, shy frog that lives in inaccessible places (Ingram learned to identify *Rheobatrachus* by the characteristic ripples made by its jump into water); rain, fog, and dampness; and regeneration that frustrates identification (ecologists must recognize individual animals in order to monitor size and movement of populations by mark-recapture techniques. Amphibians and reptiles are traditionally marked by distinctive patterns of toe clipping, a painless and unobtrusive procedure. But *Rheobatrachus* frustrates tradition by regenerating its clipped toes, and Ingram could not reidentify his original captures). To this, we must add the usually unacknowledged bane of all natural history: boredom. You don't see your animals most of the time; so you wait and wait and wait (not always pleasant on the boggy banks of a stream in rainy season). Somehow, though, such plagues seem appropriate enough, given the subject. Frogs, after all, stand among the ten Mosaic originals: "I will smite all thy borders with frogs: And the river shall bring forth frogs abundantly, which shall go up and come into thine house, and into thy bedchambers, and upon thy bed ... and into thine ovens, and into thy kneading troughs" (Exod. 8: 2–3).

The biblical author of Exodus was, unfortunately, not describing *Rheobatrachus,* a rare animal indeed. Not a single *Rheobatrachus silus* has been seen in its natural habitat since 1979. A series of dry summers and late rains has restricted the range of this aquatic frog—and five years of no sitings must raise fears about its extinction. Fortunately, a second species, named *R. vitellinus,* was discovered in January 1984, living in shallow sections of fast-flowing streams, about five hundred miles north of the range of *R. silus.* This slightly larger version (up to three inches in length) is also a gastric brooder; twenty-two baby frogs inhabited the stomach of a pregnant female.

When discussed as a disembodied oddity (the problem with traditional, narrative writing in natural history), *Rheobatrachus* may pique our interest but not our intellect. Placed into a proper context among other objects of nature's diversity—the "comparative approach" so characteristic of evolutionary biology—gastric brooding in *Rheobatrachus* embodies a message of great theoretical interest. *Rheobatrachus,* in one sense, stands alone. No other vertebrate swallows its own fertilized eggs, converts its stomach into a brood pouch, and gives birth through its mouth. But in another sense, *Rheobatrachus* represents just one solution to a common problem among frogs.

In his review of parental care, R.W. McDiarmid argues that frogs display "the greatest array of reproductive modes found in any vertebrates" (see his article in G.M. Burghardt and M. Bekoff, *The Development of Behavior,* New York, Garland Press, 1978). Much inconclusive speculation has been devoted to reasons for the frequent and independent evolution of brooding (and other forms of parental care) in frogs—a profound departure, after all, from the usual amphibian habit of laying eggs in water and permitting the young to pass their early lives as unattended aquatic tadpoles. Several authors have suggested the following common denominator: in many habitats, and for a variety of reasons, life as a free-swimming tadpole may become sufficiently uninviting to impose strong evolutionary pressure for bypassing this stage and undergoing "direct development" from egg to completed frog. Brooding is an excellent strategy for direct development—since tadpole life may be spent in a brood pouch, and the bad old world need not be faced directly before froghood.

In any case, brooding has evolved often in frogs, and in an astonishing variety of modes. As a minimal encumbrance and modification, some frogs simply attach eggs to their exteriors. Males of Kammerer's downfall, the midwife toad *Alytes obstetricans,* wrap strings of eggs about their legs and carry them in tow.

At the other extreme of modification, some frogs have evolved special brood pouches in unconventional places. The female *Gastrotheca riobambae,* an Ecuadorean frog from Andean valleys, develops a pouch on her back, with an opening near the rear and an internal extension nearly to her head. The male places fertilized eggs in her pouch, where they develop under the skin of her back for five to six weeks before emerging as late-stage tadpoles.

In another Australian frog, *Assa darlingtoni,* males develop pouches on their undersides, opening near their hind legs but extending forward to the front legs (see article by G.J. Ingram, M. Anstis, and C.J. Corben, *Herpetologia,* vol. 31, 1975, pp. 425–29). Females lay their eggs among leaves. When they hatch, the male places himself in the middle of the mass and either coats himself with jelly from the spawn or, perhaps, secretes a slippery substance himself. The emerging tadpoles then perform like no other amphibian: they move in an ungainly fashion by bending their bodies, head toward tail, and then springing sideways and forward. In this inefficient manner, they migrate over the slippery body of their father and enter the brood pouch under their own steam. (I am almost tempted to say, given the Australian venue, that these creatures have been emboldened to perform in such unfroglike ways by watching too many surrounding marsupials, for the kangaroo's undeveloped, almost larval joey also must endure a slow and tortuous crawl to the parental pouch!)

In a kind of intermediate mode, some frogs brood their young internally but use structures already available for other purposes. I have already discussed *Rhinoderma,* the vocal-pouch brooder of Chile. Evolution seizes its opportunities. The male vocal pouch is roomy and available; in a context of strong pressure for brooding, some lineage will eventually overcome the behavioral and structural obstacles to grasp this ready possibility. The eggs of *R. darwini* develop for twenty-three days before the tadpoles hatch. For the first twenty days, tadpoles grow within eggs exposed to the external environment. But tadpoles then begin to move, and this behavior apparently triggers a response from the male parent. He then takes the advanced eggs into his vocal pouch. They hatch there three days later and remain for fifty-two days until the end of metamorphosis, when the young emerge through their father's mouth as perfectly formed little froglets. In the related species *R. rufum,* muscular activity begins after eight days within the egg, and males keep the tadpoles in their vocal sacs for much shorter periods, finally expelling them, still in the tadpole stage, into water (see article by K. Busse, *Copeia,* 1970, p. 395).

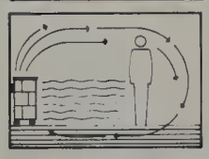
In this context, *Rheobatrachus* is less

Finally, a civilized woodstove...

You don't have to change your lifestyle—or sacrifice the beauty of your home—to enjoy the pleasure and savings of a wood or coal fire. The WESO Ceramic Tile Stove makes conventional stoves obsolete—with decorator colors, welcome convenience, unique safety, and wonderful comfort.

If you'd love a woodstove for the joy of a crackling fire and the luxurious warmth, but can't bear to put a "black box" in your living room...Or if you're fed up with the harsh, uneven heat of your current cast-iron or soapstone stove...the WESO Ceramic Tile Stove offers a solution you'll love living with.

Now available in eight different models and eight exquisite tile colors—including handpainted delft patterns—the WESO will harmonize with the most tastefully decorated home. It's one stove that won't make your room look like a foundry.



Unsurpassed comfort A typical radiant stove broils you on one side while you freeze on the other. The farther away you stand, the chillier you feel. But a WESO warms you with gentle radiant heat AND circulates convection heated air throughout your rooms. Wherever you stand you get even temperatures floor to ceiling (no cold spots!) and a mild yet penetrating warmth not even furnace-heated air can match. And WESO convection is natural—no noisy electric blower needed.

Won't take over your living space Most stoves jut out intrusively into your room, and they require 3 feet of clearance between themselves and combustibles like furniture. That's a lot of valuable room space!

A WESO's slim profile hugs your wall discreetly. Installed in front of your fireplace it looks like it was made for your hearth. And you can safely place furniture as close as 9" to the tiles.

Unmatched safety—without sacrificing heat A WESO rivals or exceeds almost any stove its size in heat output.(Some owners heat their whole house with their WESO stoves.) Yet the tiles themselves stay safe to the touch! You can actually snuggle against a WESO while it fills your rooms with warmth.

Outstanding convenience—and affordability These splendid tile heaters offer every convenience feature you could ask for, including an automatic thermostat to end constant tending, a pull-out ash pan, and a tempered glass window. WESO stoves burn cleanly with no catalytic combustor needed, and they burn wood and coal interchangeably, without the costly "conversion kits" most stoves require.

Yet contrary to what you might think, WESO stoves are not more expensive than other premium woodstoves. And all WESO features are standard. There's nothing extra to buy.

There's so much more we'd like to tell you—about the WESO's superb efficiency, its easy portability, and what WESO owners have to say. Please mail the coupon below for full details.

WESO Ceramic Tile Stoves

ANXIOUS PLEASURES

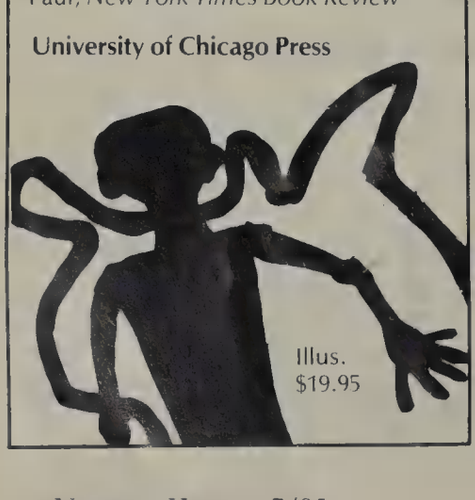
The Sexual Lives of an Amazonian People

THOMAS GREGOR

"Good fish get dull but sex is always fun," say the Mehinaku, a Brazilian forest tribe. But, Gregor shows, this claim is not strictly accurate.

"Fine ethnographic research and clear exposition....Freud taught us that for human beings, Eros always seems to deliver his favors with a dollop of anxiety. The Mehinaku teach us how true this remains even in the remote reaches of the Xingu River."–Robert A. Paul, *New York Times Book Review*

University of Chicago Press



Illus.
$19.95

an oddity than a fulfillment. Stomachs provide the only other large internal pouch with an egress of sufficient size. Some lineage of frogs was bound to cotton on to this possibility. But stomachs present a special problem not faced by vocal sacs or novel pouches of special construction—and we now encounter the key dilemma that will bring us back to mimicry in butterflies and the evolutionary problem of incipient stages. Stomachs are already doing something else—and that something is profoundly inimical to the care and protection of fragile young. Stomachs secrete acid and digest food—and eggs and tadpoles are, as they say down under, mighty good tucker (food).

In short, to turn a stomach into a brood pouch, something must turn off the secretion of hydrochloric acid and suppress the passage of eggs into the intestine. At a minimum, the brooding mother cannot eat during the weeks that she carries young in her stomach. This inhibition may arise automatically and present no special problem. Stomachs contain "stretch receptors" that tell an organism when to stop eating by imposing a feeling of satiety as the mechanical consequence of a full stomach. A batch of swallowed eggs will surely set off this reaction and suppress further eating.

But this fact scarcely solves our problem—for why doesn't the mother simply secrete her usual acid, digest the eggs, and relieve her feeling of satiety? What turns off the secretion of hydrochloric acid and the passage of eggs into the intestine?

Tyler and his colleagues immediately realized, when they discovered gastric brooding in *Rheobatrachus*, that suppression of stomach function formed the crux of their problem. "Clearly," they wrote, "the intact amphibian stomach is likely to be an alien environment for brooding." They began by studying the changes induced by brooding in the architecture of the stomach. They found that the secretory mucosa (the lining that produces acid) regresses while the musculature strengthens, thus converting the stomach into a strong and chemically inert pouch. Moreover, these changes are not "preparatory"—that is, they do not occur before a female swallows her eggs. Probably, then, something in the eggs or tadpoles themselves acts to suppress their own destruction and make a congenial place of their new home. The Australian researchers then set out to find the substance that suppresses acid secretion in the stomach—and they have apparently succeeded.

P. O'Brien and D. Shearman, in a series of ingenious experiments, concentrated water that had been in contact with developing *Rheobatrachus* embryos to test for a chemical substance that might suppress stomach function in the mothers. They dissected out the gastric mucosa (secreting surface) of the toad *Bufo marinus* (*Rheobatrachus* itself is too rare to sacrifice so many adult females for such an experiment) and kept it alive in vitro. They showed that this isolated mucosa can function normally to secrete stomach acids and that well-known chemical inhibitors will suppress the secretion. They then demonstrated that water in contact with *Rheobatrachus* tadpoles suppresses the mucosa, while water in contact with tadpoles of other species has no effect. Finally, they succeeded in isolating a chemical suppressor from the water—prostaglandin E_2. (The prostaglandins are hormonelike substances, named for their first discovery as secretions of the human prostate gland—though they form throughout the body and serve many functions.)

Thus, we may finally return to mimicry and the problem of incipient stages. I trust that some readers have been bothered by an apparent dilemma of illogic and reversed causality. The eggs of *Rheobatrachus* must contain the prostaglandin that suppresses secretion of gastric acid and allows the stomach to serve as an inert brood pouch. It's nice to know that eggs contain a substance for their own protection in a hostile environment. But in a world of history—not of created perfection—how can such a system arise? The ancestors of *Rheobatrachus* must have been conventional frogs, laying eggs for external development. At some point, a female *Rheobatrachus* must have swallowed its fertilized eggs (presumably taking them for food, not with the foresight of evolutionary innovation)—and the fortuitous presence of prostaglandin suppressed digestion and permitted the eggs to develop in their mother's stomach.

The key word is *fortuitous*. One cannot seriously believe that ancestral eggs actively evolved prostaglandin because they knew that, million of years in the future, a mother would swallow them and they would need some inhibitor of gastric secretion. The eggs must have contained prostaglandin for another reason or for no particular reason at all (perhaps just as a metabolic byproduct of development). Prostaglandin provided a lucky break with respect to the later evolution of gastric brooding—a historical precondition fortuitously available at the right moment, a sine qua non evolved for other reasons and pressed into service to initiate a new evolutionary direction.

Darwin proposed the same explanation

r the initiation of mimicry—and as a neral solution to the old problem of in-pient stages. Mimicry works splendidly s a completed system, but what gets the rocess started along one potential path-ay among many? Darwin argued that a imicking butterfly must begin with a ight *and fortuitous* resemblance to its odel. Without this leg up for initiation, ne process of improvement to mimetic erfection cannot begin. But once an acci-ental, initial resemblance provides some ight edge, natural selection can improve ne fit from imperfect beginnings.

Thus, Darwin noted with pleasure ates's demonstration that mimicry al-ays arose among butterflies more prone o vary than others that never evolve mi-netic forms. This tendency to vary must e the precondition that establishes fortu-ous initial resemblance to models in ome cases. "It is necessary to suppose," Darwin wrote, that ancestral mimics "ac-idently resembled a member of another nd protected group in a sufficient degree o afford some slight protection, this hav-ng given the basis for the subsequent ac-uisition of the most perfect resem-blance." Ancestral mimics happened to esemble a model in some slight degree—nd the evolutionary process could begin. The eggs of *Rheobatrachus* happened to ontain a prostaglandin that inhibited gas-ric secretion—and their mother's stom-ch became a temporary home, not an en-gine of destruction.

New evolutionary directions must have uch quirky beginnings based on the fortu-tous presence of structures and possibil-ties evolved for other reasons. After all, in nature, as in human invention, one cannot prepare actively for the utterly unex-pected. Gastric brooding must be an ei-ther-or, a quantum jump in evolutionary potential. As Tyler argues, what interme-diary stage can one imagine? Many fishes but no frogs) brood young in their mouths—while only males possess throat pouches, but only female *Rheobatrachus* broods in its stomach. Eggs can't develop halfway down the esophagus.

We glimpse in the story of *Rheobatra-chus* a model for the introduction of cre-ativity and new directions in evolution (not ust a tale of growing bigger or smaller, fiercer or milder, by the everyday action of natural selection). Such new directions, as Darwin argued in resolving the problem of incipient stages, must be initiated by fortuitous prerequisites, thus imparting a quirky and unpredictable character to the history of life. These new directions may involve minimal changes at first—since the fortuitous prerequisites are already present, though not so utilized, in ances-tors. A female *Rheobatrachus* swallowed its fertilized eggs, and a striking new be-havior and mode of brooding arose at once by virtue of a chemical fortuitously present in eggs and by the automatic ac-tion of stretch receptors in the stomach. Such minimal changes are pregnant with possibilities. Most probably lead nowhere beyond a few oddballs—as with *Rheoba-trachus*, probably already well on its way to extinction.

But a few quirky new directions may become seeds of major innovations and floods of diversity in life's history. The first protoamphibian that crawled out of its pond has long been a favorite source of evolutionary cartoon humor. The captions are endless—from "see ya later as alli-gator" to "because the weather's better out here." But my favorite has always been "here goes nothing." It doesn't hap-pen often, but when nothing becomes something, the inherent power of evolu-tion, normally an exquisitely conservative force, can break forth. Or, as Reginald Bunthorne proclaims in Gilbert and Sullivan's *Patience* (which evolution must have before all else): "Nature for restraint too mighty far, has burst the bonds of art—and here we are."

Stephen Jay Gould teaches biology, geol-ogy, and the history of science at Harvard University.

If you spend more than an hour at a time with your binoculars, you need Trinovid® Binoculars.

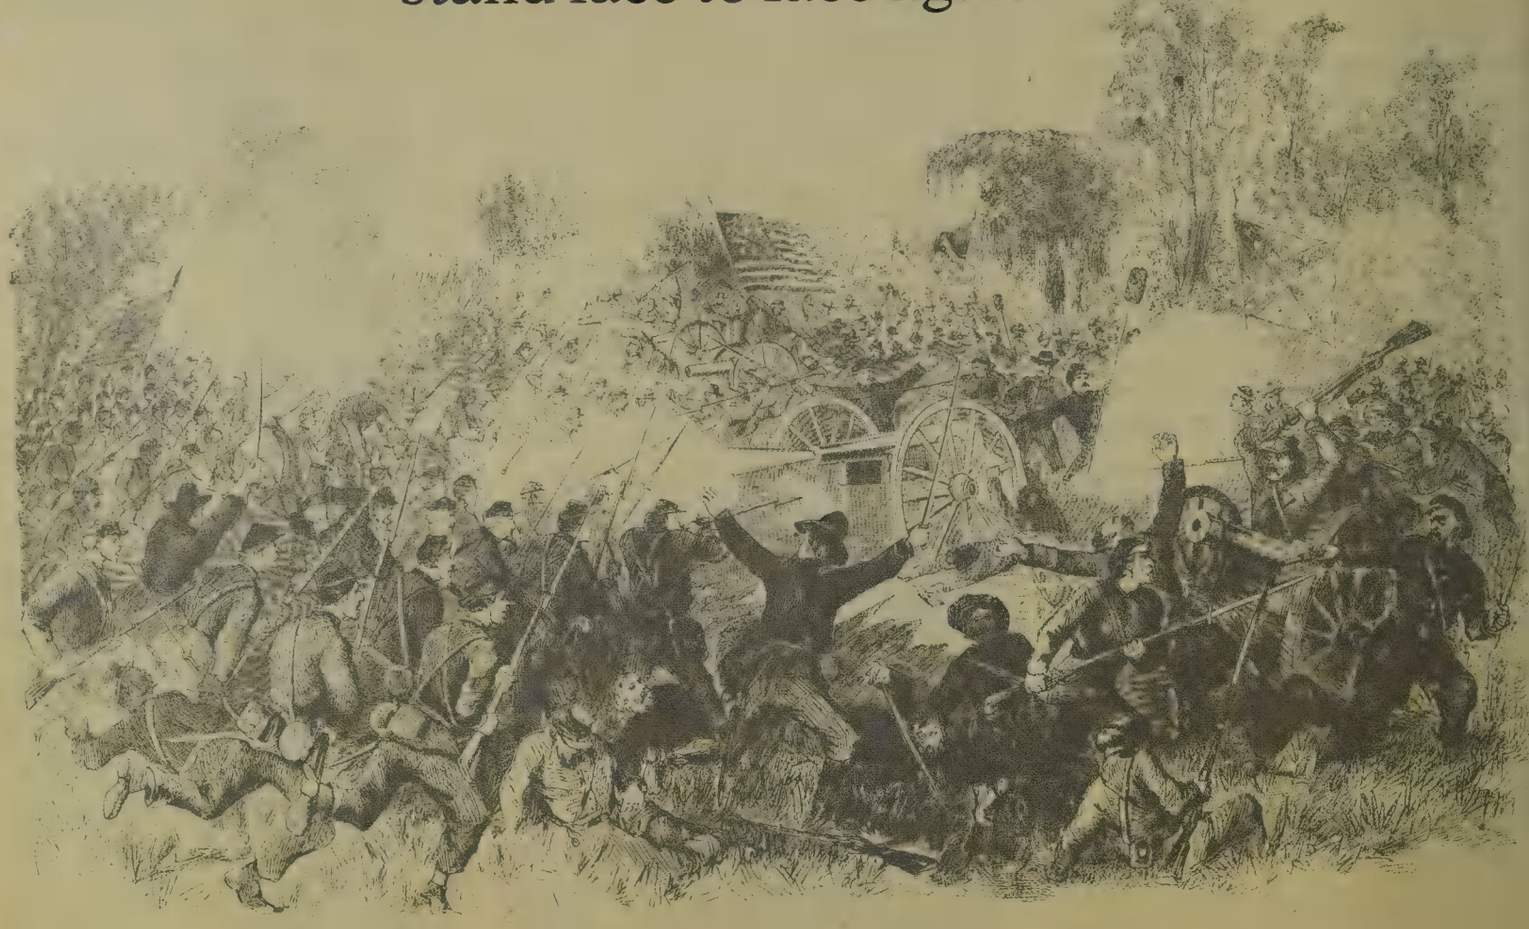
The armies of the Blue and Gray stand face to face again . . .



THE NATIONAL HISTORICAL SOCIETY

CIVIL WAR CHESS SET

An official issue, available only by direct subscription.
Price: $17.50 per sculpture.
Limit: One set per subscriber.
Please subscribe by July 31, 1985.

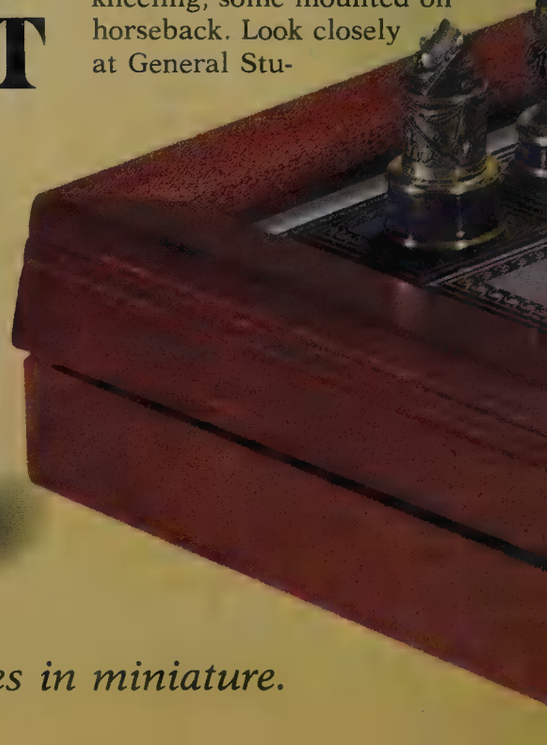
1861-1865. The War Between the States. A conflict that still touches the American soul. And so, it is in lasting tribute to the heroes of both North and South, that The National Historical Society, founded in Gettysburg, now dedicates the Civil War Chess Set.

Once again, the armies of the Blue and Gray stand face to face. The *Kings*: Ulysses S. Grant for the Union. Robert E. Lee for the Confederacy. *Bishops* and *Knights*: Sherman, Meade, Custer, Sheridan ... Jackson, Stuart, Beauregard, Wheeler. Even the *Pawns*—the Union's relentless Iron Brigade facing Jackson's famed Stonewall Brigade.

A roll call of glory.

A towering achievement in marvelous miniatures. And each figure a work of art—a new and original *portrait sculpture*, created exclusively for The National Historical Society by the world famous artists and engravers of The Franklin Mint.

Each chessman is hand-cast in fine pewter, then set on a solid brass base, richly enameled in Union Blue or Confederate Gray. Some are shown standing, some kneeling, some mounted on horseback. Look closely at General Stu-



A dramatic collection of authentic portrait sculptures in miniature.

art, a Confederate *Knight*—his boots, saber, saddle bags, gloves, jaunty beard, and rakish hat with ostrich plumes—"Jeb" Stuart rides again.

Note, too, the etched strength in Lee's face ... Sherman's inimitable bow-tie ... Custer's long hair, blowing wild as he spurs his mount. This is detail authentic and astonishing. American heroes from the pages of history—to live again in your office, home or den.

And just as The National Historical Society Civil War Chess Set is *unique*, so too is its playing board. A handsome, pewter-finished field, with a specially fitted case to house all 32 chessmen. And both are provided *at no additional charge*, as are a Certificate of Authenticity and specially written reference folders.

Here is a possession to evoke admiration from all who see it. American art of heirloom quality—destined to bring you and your family endless pleasure through the years. A chess set eminently *worthy* of being passed on down the generations.

Convenient and affordable acquisition plan

Take note, however, that this historic chess set may be obtained *only* by direct subscription. There is a limit of one complete set per subscriber. And no advance payment is required.

Just complete and return the accompanying Subscription Application by July 31. Then, you will receive *two* sculptured chessmen every *other* month; but you will be billed for only *one* chessman at a time—just $17.50 per month. The playing board will be included at no additional charge. And you will even be given the opportunity to complete your set earlier—though you will be under no obligation to do so.

The next move is yours. You would be wise to make it by July 31, 1985.

Shown actual size.

Enlarged to show detail.

© 1985 NHS

SUBSCRIPTION APPLICATION

Please mail by July 31, 1985.
Limit: One complete set per subscriber.

The National Historical Society
c/o The Franklin Mint
Franklin Center, Pennsylvania 19091

Please enter my subscription for The National Historical Society Civil War Chess Set, consisting of thirty-two playing pieces, each crafted of fine pewter, mounted on a solid brass pedestal base, and emblazoned with rich enamel color.

I need send no money now. I will receive two new playing pieces every *other* month, but will be billed for just one chessman at a time—$17.50* per month—beginning when my first shipment is ready to be sent to me. I will receive the fitted presentation case and pewter-finished chess board at no extra charge.

**Plus my state sales tax and $.50 per chessman for shipping and handling.*

Douglas Gruenau

Alpine Garden, New Hampshire

by Robert H. Mohlenbrock

When he stood atop New Hampshire's Mount Washington, P.T. Barnum remarked, "This is the second greatest show on earth." Highest of the eleven peaks that make up the Presidential Range, Mount Washington lies in the heart of White Mountain National Forest. The 6,288-foot summit extends well above the region's tree line, and bleak tundra covers nearly eight square miles of the surrounding territory. Here, one thousand feet down and east of the mountaintop, is a natural area known as the Alpine Garden. Two-thirds of the garden's 110 kinds of flowering plants are alpine species whose major range is far to the north. Many plant species that live here are more common in Labrador, Newfoundland, and areas in the Arctic. Alpine azalea, moss cassiope, mountain heath, alpine bearberry, and two eyebrights range from Newfoundland and the mountains of Quebec south only to the Presidential Range. Alpine bluet grows just on the islands of Saint Pierre and Miquelon and on Mount Washington.

There are three ways to reach Mount Washington's summit and the adjacent Alpine Garden. For the nostalgic, a cog railroad makes the climb to the top in seventy minutes, as it has since 1869. The eight-mile automobile toll road takes a more circuitous route. The third way to go is to hike one of the several trails. As a botanist, I prefer the last method because it affords a close look at a variety of habitats en route.

It was a crisp and sunny late June morn-

ing when I hiked away from Pinkham Notch toward Tuckerman Ravine, on the eastern flank of Mount Washington. But at about 4,800 feet, I left the ravine forest and came out into the open, where sharp gusts of bone-chilling wind nearly took my breath away, and a heavy, wet fog hovered above me. I felt as if I had been translocated into the Arctic, and the types of plants around me contributed to the illusion. I had broken into the krummholz—"crooked wood," in German—that zone of gnarled dwarf trees a few hundred feet below the treeless tundra. Because of the fierce climate, which reduces the rate of photosynthesis, black spruces and balsam firs are only a few feet tall, despite their considerable age. Frigid and furious winds prune away all branches of these hardy plants that protrude above the layer of winter snow.

At about 5,100 feet, I passed the last of the krummholz plants, and the solemn-looking, rock-strewn slope of the Alpine Garden lay ahead. The garden surface has been shaped by frost through the centuries. Permanent moisture and fluctuating low temperatures have created the subsurface soil known as permafrost, which has remained frozen for thousands of years. Above the permafrost is a layer of water-saturated soil that repeatedly freezes and thaws, heaving rocks and pebbles out of the ground. Sometimes the rocks are deposited in rings and polygons, sometimes in small piles. In places, thawing, saturated soil creeps downslope over bedrock (a process known as solifluction), eventually forming very low, undulating ridges called solifluction terraces.

Plants in the Alpine Garden contend with bitter conditions. The mean annual temperature on the tundra is only 27 degrees Fahrenheit, with July the warmest month at 48 degrees. The winds surpass 100 miles per hour every month of the year, with a world high of 231 miles per hour recorded in 1934. Clouds block out the sun about 75 percent of the time, mostly in the form of wet fog, especially on the western slopes. Winter snow piles up an average 195 inches; during the winter of 1957–58, 344 inches fell on Mount Washington.

The plants that have adapted to life in the tundra make the most of the natural features. Something as seemingly unimportant as the lee side of a rock may give just enough protection for a seedling to grow into a mature plant. The nearly imperceptible ridge of a solifluction terrace may provide the right exposure to the sun for seeds to germinate and develop. Snowbanks built up by the freezing, hurricane-force winds insulate the parts of plants that otherwise would perish during the winter. Natural springs from high up on Mount Washington flow out across the Alpine Garden in clear, cold streams, offering the bordering plants the water they need to complete their life cycle during the short growing season.

Most plants on Mount Washington are perennials, with taproots that penetrate more than a foot into the soil. Because they have a stable root system, they needn't perpetuate themselves every year by flowering and forming fruit and seed. If the conditions are especially harsh, a plant need only form a few new leaves to replenish its supply of stored food.

Since the growing season in the Alpine Garden seldom lasts more than one hundred days, plants begin their life cycle as early as possible. The three-toothed cinquefoil, for example, begins to flower as soon as the temperature climbs above freezing. The flower buds in such species are formed during the previous season and kept safely protected by surrounding tissues over the winter.

MOUNTAIN TRAVEL®
The Adventure Company

To avoid the intensity of the wind, most alpine plants are very short, and often they are plastered against the ground. While most willows are upright trees or shrubs, the Alpine Garden's bearberry willow grows in dense mats only two inches high. Other plants, like the diminutive moss campion, have branches tightly woven into a rounded cushion that surrounds a deep taproot. At the center of the cushion, where the branches and leaves are densely packed, the temperature is warmer than in the surrounding environment. The threat of desiccation is also minimized, because the wind tends to blow over the rounded form.

Small, compact leaves, like those of the moss cassiope, are common in alpine species because they require less energy for their maintenance. Plants with grasslike leaves, such as sedges and rushes, are also prominent members of the alpine flora. Their slender leaves are less likely to be shredded by the strong winds. Occasional patches of sphagnum, or peat moss, as well as a few other plants, are colored by anthocyanin, a reddish blue pigment. Anthocyanin absorbs rays of light, helping to keep plant tissues warm.

Although at first the Alpine Garden appears uniform, discrete plant communities can be recognized. On most of the slopes that grade down to the level terraces, clumps of alpine rush are surrounded by lower, compact growth of mountain cranberry and bog bilberry, two heaths with pink bell-shaped flowers and small, leathery leaves. By late July, the mountain cranberry forms bright red acidic berries, while the bilberry bears sweet, black fruit. Other plants in this community include the mountain sandwort, whose bright white flowers enliven the landscape. The sandwort's penchant for growing along the edges of trails makes hiking in the dense fog somewhat easier.

In shallow depressions, and on the lee side of rock piles, a dwarf shrub heath community often develops. Low sweet blueberry, Labrador tea, and the alpine bearberry, as well as the mountain cranberry and bog bilberry, form dense mats as much as twelve inches deep. Within the boundaries of rock polygons, solid masses of diapensia often grow so densely that they prevent other flowering plants from becoming established. Diapensia is a cushion plant that resembles members of the heath family except for its flowers.

The streams that radiate across the Alpine Garden are lined with dark green bands of vegetation. The streamsides are the most interesting of the plant communities because they contain a diversity of species. One is the tea-leaved willow, which looks like a normal willow in miniature, having a stature of no more than two feet. Another curious plant, the alpine bistort, forms several pale pink flowers, but none of the flowers set seed. Instead, tiny balls of plant tissue, called bulblets, develop below the base of the flowers. After dropping to the ground, the bulblets can grow into new plants without benefit of pollination and fertilization.

The range of some of its alpine species sets the Alpine Garden apart from similar habitats elsewhere in New England. At one time scientists thought that arctic plants reached the White Mountain region when they ranged southward in advance of continental glaciation. In this view, Mount Washington and adjacent peaks became areas of refuge as the glaciers marched past at lower elevations.

The Smell of Success

As a little wildflower in the Rocky Mountains discovered, it sometimes pays to make yourself unattractive

by Candace Galen

For poets, the sweet fragrances of flowers have long served as symbols of purity and happiness. Perfume manufacturers have more worldly interests; they have created a lucrative industry built on the recognition that fragrances are powerful attractants. Evolutionary ecologists, too, have been inspired by floral scents, which seem to so neatly serve the interests of both plants and their pollinators.

But do floral scents simply signal the presence of pollen or nectar to foraging birds and bees? In many flowering plants, the answer appears to be yes. Some plants—the blueberry, for example—produce scented compounds in the nectar itself, where they may actually be perceived as flavoring by the bees that pollinate the flowers. But the scent that attracts pollinators may emanate from another part of the flower entirely. Furthermore, other floral smells appear to play no role in attracting potential pollinators. Why would any plant evolve such a seemingly useless and chemically costly trait? Clearly, the role of floral fragrance is more complicated than it appears at first glance, and this is where the evolutionary ecologist can make a contribution.

In late June, the snow cover of alpine Colorado begins to recede, exposing a carpet of cushion plants, forbs, willows, and grasses. The stature of these plants, like the twisted forms of the bristlecone pines only a few steps below, testifies to the presence of constant, often buffeting winds. Here, on the slopes of the Rockies, grows an unusual member of the phlox family: *Polemonium viscosum*. Better known as sky pilot because its dense flower cluster rises like a periscope above the alpine tundra, this wildflower is a particularly interesting one from the point of view of floral fragrance: some sky pilot flowers produce a sweet smell; others are distinctly skunky. Occasionally flowers of a single plant have both scents, but usually the skunky smell masks the sweet one.

The two scents of sky pilot flowers possess some markedly different chemical characteristics. Interestingly, they are also produced at different sites within the flower. As an evolutionary ecologist, I was curious to know what forces led to the exis-

Below: The fragrance of a sweet-scented sky pilot emanates from deep within the center of each violet blue flower. The odor of skunky flowers comes from sticky hairs on the small green leaves encircling each blossom. The green leaves enclosing flower buds may also have a skunky smell. Right: Unlike bumblebees—which are faithful to one flower species—flies are fickle and inefficient pollinators. The fly on this alpine avens blossom may be depositing pollen picked up on a sky pilot.

Bob Rozinski

tence of the two scent variants, or morphs, in this species, and I spent five summers of fieldwork in central Colorado trying to find out.

To my initial surprise, many of the people I met in the course of my research spoke of encounters with the skunky morph of the sky pilot but were not familiar with the sweet one. Similarly, leafing through herbarium sheets at Colorado State University and the University of Colorado at Boulder, I found several reports of floral scent in *P. viscosum,* and nearly all alluded to skunkiness. Yet both variants commonly occur together, and extensive stands of plants with sweet-scented flowers grow on the tundra near Independence Pass and next to Rocky Mountain National Park's well-traveled Trail Ridge Road.

I soon began to understand the reason for the common perception that sky pilot always smells skunky. In my study area west of the town of Fairplay on Pennsylvania Mountain, I found that plants with skunky-scented flowers were most abundant at more accessible, lower sites in the krummholz (the area of stunted, dwarfed trees found at timberline), whereas those with sweet-scented flowers were increasingly common at higher elevations, on the slopes of the upper tundra. Thus, hikers who take time to smell the flowers are likely to encounter the unpleasant morph first, and since the two variants look identical, they probably avoid sampling sky pilot higher up on the trail.

I suspect that botanists also tend to record unusual features, such as skunky scent, while accepting with little fanfare the sweet fragrances that flowers are assumed to have. I, too, might have missed the sweet-smelling sky pilots if Peter Kevan—then at the University of Colorado at Colorado Springs and now at the University of Guelph in Ontario—had not introduced me to flowers of both scents on my first tour of Pennsylvania Mountain. Later, reading through my sun-bleached copy of William Weber's field guide to the Rocky Mountain flora, I was pleased to find much attention paid to floral variation, including a description of scent differences in *P. viscosum.*

Each sky pilot plant usually bears eight to twelve tightly packed flowers, pollinated by insects. Flowers consist of a fused ring of small, green sepals encircling a funnel-shaped corolla of violet blue petals. Inside is a whorl of five bright orange, pollen-bearing anthers. The ovary sits upon the base of the corolla, on a disk of tissue that secretes nectar. In a sweet-scented flower, fragrance emanates from this area and becomes detectable when the flower opens. The scent of skunky flowers is not associated with the nectary; it appears to be a product of the sticky hairs on the outer surface of the sepals and is present in the bud and fruit, as well as the blossom. Chemical studies have shown that the sepals of skunky-scented flowers contain a much broader spectrum of volatile chemicals than those of sweet ones. But to un-

Kent and Donna Dannen

derstand how these two fragrances function, I needed to look beyond chemistry. To get a clearer picture, I decided to study the characteristics of the various insects attracted to flowers of each scent.

In a very general sense, the livelihood of all flower-visiting insects depends on their skill in distinguishing flowers on the basis of such features as form, color, texture, and scent. A bee, for example, may use form to spot appropriate plants from a distance but depend on fragrance to identify particularly attractive flowers from close up. Plants with desirable flowers may benefit from the bee's visit by receiving more pollen and ultimately producing more viable seeds than those with rejected flowers. Because seed production, which botanists call seed set, is an intrinsic part of a plant's fitness (the more seeds, the more potential offspring), bees and other pollinators may act as agents of natural selection. By exercising their floral preferences, they shape the evolution of flower traits in the plants they service.

Not all insects have the same effects on a plant's reproductive fitness, however. The insects that visit flowers are a diverse lot. Bumblebees, solitary bees, syrphid flies, anthomyiid flies, muscid flies, and ants are all commonly found on flowers of *P. viscosum*. Yet their feeding activities at these flowers differ markedly. Bumblebees and ants imbibe nectar, syrphid flies and solitary bees gather both nectar and pollen, and shorter-tongued anthomyiid and muscid flies collect only pollen. Except for ants, all of these insects carry some pollen grains from one plant to another, and since sky pilot requires such outcrossing to set full seed, a visit from any of these insects can be valuable. But from the plant's perspective, some visitors are more beneficial than others. The insect's size, posture, and behavior may make an important difference. The sky pilot's stigma—the sticky, pollen-receiving tip—sticks out slightly beyond the center of the corolla opening. A gap of about five millimeters separates it from the pollen-bearing anthers. Pollen-gathering flies that alight on the flowers are small and can feed on the anthers without brushing against the stigma; thus they remove pollen but seldom deposit any. Flies are also fickle; they are as apt to move onto neighboring cinquefoil or avens flowers as to go from blossom to blossom of *P. viscosum*. In such a case, the sky pilot pollen may be lost before reaching its destination.

In contrast, bumblebees, especially the large, burly queens of *Bombus kirbyellus*, are well suited to transfering pollen among sky pilot plants. A bumblebee queen probing the nectary at the base of the corolla receives a dusting of pollen on her face and thorax. And unlike flies, individual bumblebees are faithful to one species, and, at least within single foraging trips, rarely sample more than one kind of flower. A foraging queen may carry hundreds of *P. viscosum* pollen grains at any time. As she moves systematically from flower to flower, she may leave ten to fifty grains on the stigma of each flower visited. Bumblebees serve the host plant well.

Some of the wildflower's insect visitors are not beneficial at all, however. These, in the words of nineteenth-century naturalist Aubrey Kerner, are "unbidden guests," typically stealing nectar or pollen without causing pollination. Ants are notorious for this kind of behavior. In Colorado, the common alpine ant, *Formica neorufibarbus gelida*, depends on flower nectar as a major source of food. In 1979 and 1981, more than a fourth of the sky pilot plants I examined had been parasitized by these nectar-stealing ants. In their efforts to reach the nectar-producing disks, the ants damage the ovaries and sever the slender styles at the base, causing them to drop from the flowers. Accordingly, seed set in ant-damaged flowers is negligible.

I found that I could prevent damage of this kind by coating the plant stems with

rings of Tanglefoot, a sticky substance that foresters use to keep insects from attacking tree wounds. Knowing that some plants of tropical and temperate areas have developed elaborate barriers, ranging from thickened bracts to sticky exudates, to keep ants from their inner floral tissues, I wondered if all *P. viscosum* plants were equally susceptible to ants or if some had developed natural Tanglefoot-like barriers. In particular, I wondered if the unusual scent variation found in this species might be related to such a barrier. To answer this and other questions about sweet- and skunky-scented flowers, I looked in greater detail at the insects visiting the sky pilot in the krummholz and tundra environments.

Whether walking through the stubby growth of the krummholz or on the open tundra slopes, summer hikers on Pennsylvania Mountain may hear the low-pitched buzzing of active bumblebees, notice flies basking on sun-warmed blossoms, and pause to brush ants off of their wool socks. Looking more closely—following bees on their foraging trips, for example—will reveal slight differences in the two environments.

In the krummholz, sky pilot blooms in late June, when thousands of willow catkins are also flowering. Attracted to the tiny droplets of nectar glistening on the willow flowers, bumblebees only occasionally visit any other type of flowers, including sky pilot. In this area, sky pilot appears to depend largely on flies and solitary bees for pollination. Interestingly, however, if plants are surrounded by cages that permit the smaller insects to enter but exclude bumblebees, their seed set drops to about half that of uncaged neighbors. Apparently, close to half the seeds produced by flowers in the krummholz result from only a few bumblebee visits, attesting to

Kent and Donna Dannen

Left: In the Rocky Mountains, a single field may contain both sweet- and skunky-scented sky pilots. At lower elevations, skunky-scented plants are more common, leading many hikers to the misperception that the species always has an unpleasant smell. Below: Like the hikers, bumblebees avoid skunky sky pilots. Consequently, such plants are more often visited by pollen-gathering insects, such as this fly. These insects are often so small that they may feed on the orange anthers without depositing any pollen on the sticky white stigma just five millimeters away.

Kent and Donna Dannen

he remarkable effectiveness of bumble-ees as pollinators of *P. viscosum.*

The situation is even more dramatic on he tundra. There, similar screening re-ults in a tenfold decrease in seed produc-ion. Few willows grow on the tundra, and he bumblebee queens gather nectar al-most exclusively from *P. viscosum*, at east early in July, when the species is in loom at high elevations. Flies on the tun-ra prefer to feed on the flat yellow flow-rs of the alpine avens and so have little ef-ect on the seed set of the sky pilot plants rowing there.

Ants, like flies, are most common on sky pilots at relatively low altitudes. While the alpine ant tolerates cold better than any other ant in Colorado and has been found at 14,100 feet, it is much more abundant lower down, in the subalpine. On Pennsylvania Mountain, ants are common in flowers of *P. viscosum* from the krummholz to just over 11,800 feet on the eastern slopes, and about four plants in ten have flowers damaged by ant visits. At sites above 12,800 feet, near the summit, only about one plant in ten has damaged flowers.

Thus, both the number of insects and the proportion of sweet to skunky sky pilots on Pennsylvania Mountain vary to some extent with elevation. Plants with sweet-scented flowers are most common on the tundra, where bumblebee pollination is the rule, and at least on the upper slopes, ants rarely parasitize blossoms. Conversely, plants with skunky-scented flowers dominate in the krummholz, where they are more likely to be damaged by ants and where pollination is often effected by flies and solitary bees. When I discovered this pattern, I thought it suggested a relationship between the abundance of different kinds of flower visitors and the success of the two floral morphs. But to predict the form that this relationship might take, I needed to learn the insects' scent preferences. Therefore, during several of the summers I spent on Pennsylvania Mountain, I watched flies, solitary bees, and bumblebees in flight, keeping track of each kind of insect in the environment where it was most common and recording the number of times that each forager chose sweet- or skunky-flowered plants. In the krummholz, most flies and solitary bees appeared equally likely to frequent sweet- or skunky-scented blossoms, with the result that the two kinds of flowers received about the same number of visits from these pollinators. Only the anthomyiid and muscid flies, the least adept of available pollinators, showed any preferences, visiting skunky flowers twice as often as expected.

On the tundra, a somewhat different pattern emerged. At the elevation where my observations were made, plants with sweet-scented flowers were twice as common as those with skunky ones, yet bumblebees chose sweet plants more than six times as often as their skunky neighbors. Since both variants secrete about the same amount of nectar, I was surprised to find bumblebees actually avoiding plants with skunky flowers and visiting, instead, more distant, sweet-smelling flower heads. Perhaps the skunky scent confuses or repels the bees. Alternatively, sweet scent might guide them to the nectary, reducing

Sky pilot shares its alpine environment with many other kinds of wildflowers, including alpine sunflower, chiming bell, yellow paintbrush, avens, and cinquefoil.

Kent and Donna Dannen

the time spent locating and removing nectar in each flower. If so, the energetic costs of visits to sweet-scented flowers would be lower than visits to skunky ones. Finding the right answer requires asking more questions and studying the bees' foraging behavior in more detail, a course I hope to pursue in the future. Regardless of which rule bees follow in rejecting skunky-flowered plants, however, their preference is clear, and it is likely to have important consequences for the relative success of the two floral morphs on the tundra, where bumblebees account for 90 percent of the pollination that plants receive.

My next query concerned the ants' scent preferences. During 1979 and 1981, I monitored ant activity in the krummholz by keeping track of an exclusive trademark of ant parasitism: flowers with missing styles. In both years, more than half the plants with sweet-scented flowers in my census area had some of their blossoms damaged by ants. Floral parasitism of neighboring skunky-flowered plants was much less common. Ants, like their distant relatives the bumblebees, prefer the sweet morph. A simple experiment suggested why. Ants placed gently on stems of sweet-flowered plants crawl upward over the sepals into the open flowers. Placed on skunky-flowered plants, most ants get as far as the bases of the sepals and then retreat down the stems. Evidently, they are repelled by the viscous skunky substance coating the sepal hairs. Moreover, as I found when I conducted further experiments, skunky scent alone can invoke retreat.

If skunkiness is so unpopular, why does it persist? In essence, depending on the environment, the benefit that comes from avoiding flower parasites may outweigh that of attracting the best pollinators. The results of two additional field experiments provided further support for the idea that the predominance of skunky-scented plants in the krummholz and of sweet-scented ones on the tundra is due, at least in part, to the changing balance of bumblebee and ant visits.

On the tundra, I cross-pollinated flowers on several plants, both sweet and skunky, growing just below the summit of Pennsylvania Mountain. Flowers on neighboring plants were left alone and received only natural pollination. As expected in an environment where ant damage is minimal and bumblebees account for most of the pollination, naturally pollinated sweet-scented flowers contained about one and a half times as many seeds as their skunky-scented counterparts. However, regardless of scent, all the flowers that received extra hand pollination produced large numbers of seeds. Accordingly, on the high tundra, skunky-flowered plants appear to be at a disadvantage, but it is not due to any intrinsic inability to set seeds—they are simply less attractive to the all-important bumblebees.

Farther down the mountain in the krummholz, I painted Tanglefoot around the stems of randomly chosen sweet-flowered and skunky-flowered plants. Later, I harvested the dry fruit capsules of these as well as other, unprotected neighboring plants. Counting the seeds, I found that ants had little effect on seed set of plants with skunky-scented flowers. In contrast, protecting sweet-flowered plants more than doubled their seed production.

Surprisingly, though, even when sweet-flowered plants were protected from ants, they were not guaranteed the same seed set as their skunky-flowered neighbors in the krummholz. In some locations, th morphs had equal seed set in the absenc of ants, but in others, plants with skunk flowers continued to set more seeds. Thes results suggest that other factors—per haps the pollinating activity of flies or in trinsic physiological differences betwee the two morphs—may come into play i determining morph abundance in lowe elevations. Still, the experiment showe clearly that under conditions in which th floral morphs might otherwise do equall well, damage from nectar-stealing ants likely to cause the seed set of sweet-flow ered plants to fall well below that of the skunky-flowered neighbors. In those env ronments, ants act as agents of natural se lection, favoring the persistence of skunk sky pilots.

Pennsylvania Mountain is certainly no the only spot where the availability of po linators and flower parasites varies, an the sky pilot is unlikely to be the onl flower in which a sweet scent sometime proves to be a liability. Seen in this ligh differences within or among plant specie in such flower features as chemistry, odo and even form might be better evaluate as responses not only to the senses an preferences of pollinators but to those parasites and predators as well. The sme of success is not always sweet.

Maori Images

To the Maori, photographs are both sacred and profane

by Michael King

In 1968, when I began research on traditional tattooing among the Maori of New Zealand, I became aware that Maori attitudes toward photography differed sharply from European ones. In the course of my project I brought a photograph of a deceased woman with a chin tattoo to another woman, Makere Hose, for identification. Mrs. Hose held the framed portrait for a long time, staring at it. She began to cry, silently at first, then aloud. After about ten minutes she stood the picture on a shelf in her living room and began to talk to the deceased woman in Maori. "Ah. It's a long time since we've been able to look at each other. It's a long time since we've been able to talk. But you seem just the same. So. You're with your mother and grandmother at last, eh?"

Despite my presence, Mrs. Hose showed no sign of self-consciousness. I had been sitting when she began her lament but rose to my feet again because it seemed disrespectful to sit through what was in effect a religious ritual. Half an hour after I had handed her the photograph, she turned to me and said: "It's Rehara. Rehara Maki. She came from Waharoa, but she attended all our *hui* [gatherings]. She died over a year ago. Her *moko* [chin tattoo] was done by Kuhukuhu."

Being inexperienced in the ways of the Maori, I was perhaps less sensitive than I would be today. I wanted to understand, and so I asked intimate questions. "You treated that photograph as if it were a living person. Why?" "Ah," said Mrs. Hose. "It's got her image, you see. And that image is her *mauri* [life force]. Whenever I see a picture of a person, I see the *mauri*, then it's alive, never mind that the person's dead."

She elaborated when I asked if I could arrange for her own photograph to be taken. "No, " she said. "You can look at me, you can look at my *moko*. But you can't photograph it. Because if you do that you are taking away some of my *mauri*. And when that happens people lose their spiritual protection, and they are diminished. If it happens too much, they die, like Rehara here. I don't want that to happen to me."

Shortly after talking to Mrs. Hose, I took a photographer to the village of Honikiwi to a woman who *was* prepared to be photographed, a near-centenarian named Kirikino Epiha. Her portraits turned out well and highlighted her deeply chiseled chin tattoo, which was done about 1900. I sent a framed copy back to the old lady and her family as a gift of thanks. Within weeks I got news that Kirikino had died. I was unable to attend the mourning ceremony. When I finally did get back to Honikiwi, Kirikino's daughter, herself an old woman, told me an extraordinary story.

"We put your photograph at the foot of Mum's coffin, so that the mourners could see it as they arrived. As each group came up to the tent where she lay in state, the glass on the picture misted over. All except the nose. You could still see the nose." "What did that mean?" I asked, totally confused. "The misting over meant that Mum was crying with the mourners. But the fact that her nose was visible meant that she was also *hongi*-ing with them [the Maori custom of pressing noses with visitors], making them welcome."

Both these incidents introduced me to attitudes I was to encounter often among conservative Maori—those who believe in and practice Maori values—over the next fifteen years. These Maori respected photographic images to a degree that bordered on reverence; when friends or relatives died, they wanted photographs more than anything else to remember them by. But they remained apprehensive about being photographed. Old people in particular were targets for the cameras of Europeans, and since, inevitably, some of those old people died within a short time of be-

A daguerreotype of the Barrett sisters, left, taken in 1852, is the oldest surviving Maori image. The Barretts, products of an interracial marriage and living in European-style homes, were not typical Maori. Traditional Maori communities were not photographed until the development of the wet-plate method in the late 1850s.

Taranaki Museum

The village meetinghouse, below, was regarded as a repository for ancestral presences. By the late nineteenth century, photographs of the recently deceased members of a clan were being hung on the inside walls.

Ngai Tahu Archive

ing photographed, the apprehension was reinforced.

The ambivalence is strongest at Parihaka Pa in Taranaki. This community values photographs of its historic personalities and its previous buildings (it was a thriving town in the late nineteenth century) more than any other I know. Yet it also forbids bringing cameras into the village. The act of photography by non-Maori is condemned; the results of such photography are esteemed highly.

Still other factors affect Maori attitudes to photography. Some Maori fear that Europeans will profane their sacred images—such as those of revered ancestors, carved meetinghouses, or people with tattoos—by selling photographs of them for money. The considerable industry at work in New Zealand reproducing Maori images and placing them in profane contexts justifies this fear in Maori eyes. The most profane act possible is to associate sacred images with food, and this has been done frequently. Maori heads adorn tea towels and biscuit tins, and Maori portraits hang in hotel dining rooms.

The origin of these attitudes can be found in the history of photography in the area. Photography did not reach New Zealand until the late 1840s. The first method used in the then British colony was the daguerreotype, named after its inventor, Louis Daguerre. The process required lengthy exposures (at first some ten to fifteen minutes, later five to thirty seconds), was expensive (from ten shillings to two guineas per picture), and resulted in a single positive image. It could be seen only from certain angles, and it could not be duplicated. In New Zealand, early daguerreotype photography did not extend far beyond the controlled conditions of makeshift studios that were set up outside the homes of wealthier European settlers. Hence Maori portraits from this time are few and their range is narrow.

A daguerreotype of the Barrett sisters, taken in New Plymouth in 1852, is the earliest surviving Maori image. Because of the limitations of the process, the first Maori photographed were not typical—they were usually like the Barretts, products of interracial marriages who lived in European-style homes in coastal towns. It is also likely that such families shared European attitudes.

The wet-plate process introduced in the mid-1850s allowed greater flexibility. Although long exposures and studio-type conditions were still preferred, photographers could now carry equipment and chemicals into the field. The process was more versatile and became cheaper than daguerreotype photography. Multiple prints could be made from wet-plate negatives; thus more pictures went into circulation and more survived. Maori were still mostly photographed in towns, but beginning in the late 1850s, photographers began to move out into Maori communities.

In effect, from the time the Maori were first exposed to photography—in the late 1850s and early 1860s—they were ambivalent about the practice. In most cases the photographs themselves generated respect; in some instances, even awe and fear. Uninitiated to the mysteries of physics and chemistry, Maori were unlikely to understand the process. But they were well aware of its dramatic consequences: a person's image—his or her most intimate characteristic—could be captured at a given moment, frozen, reproduced, circulated, and retained for posterity, even af-

Men with facial tattoos were popular subjects for paintings and photographs, right. Because no tattooing was done on men after the 1860s, subjects were scarce by the early 1900s and no longer existed after the 1920s.

The penny-haka *(a dance performed for money to amuse tourists), below, was one of the most common subjects for picture postcards and contributed to the image of Maori as simpletons.*

Alexander Turnbull Library

ter the subject had died. In early photographs, some subjects, obviously not understanding what was happening, stare anxiously at the camera; others glare into the lens with complete confidence.

Most portraits from the late 1850s and the 1860s were taken in town studios such as that of the American Photographic Company in Auckland. John McGarrigle, who worked for the company, would go out into the streets and persuade Maori visiting the town to step inside and be photographed. Many of these pictures were used in the picture postcard trade, which flourished at midcentury. Because they suggested exotic and romantic images of frontier life in New Zealand, postcards of Maori were favorites for Europeans to send abroad.

But within Maori communities, where Maori mores prevailed, suspicion and even fear of photographers persisted. In 1885 photographer Alfred Burton reported that his Maori subjects along the Wanganui River called his camera a *taipo* (goblin). Some Maori refused to be photographed, others had to be bribed into cooperating. That same expression, *taipo*, was still applied to the camera in 1909, when George Bourne photographed the Maori of the remote Urewera district.

In Maori communities close to European ones, however, changes began to become apparent in the late 1880s. Once it occurred to Maori that they need not simply be passive subjects for European photographers, that they could order and arrange pictures for their own purposes, they began to look upon the process more favorably. At this time, and even more so in the 1890s, families began to commission individual and group portraits to hang in their own homes and in meetinghouses. Because the Maori have a strong sense of family, all photographs of relatives were highly prized.

Once the subject had died, the photographs were valued even more. From the 1890s, pictures were hung in meetinghouses (which were regarded as repositories for and representations of ancestral presences). They were used in mourning ceremonies to recall the deceased and the relatives who had died before him. Arranged around the coffin, the photographs were addressed during the funeral oratory as if they were living presences. These customs persist in the twentieth century and are a classic example of the Maori capacity to accommodate features of Western technology into a framework of Maori values, with a consequent strengthening of those values.

Today, the use of photographs to commemorate the dead is more elaborate. Pictures are used to represent the dead in ceremonies where bodies are not actually present, such as the *kawe mate* ritual, in which a death is commemorated after a burial, and at "unveilings" of tombstones. Since the 1970s photographs have even been used on the tombstones themselves.

Back at the turn of the century, however, another use of photography began to disturb Maori leaders. In the 1860s, Maori had scarcely noticed the then-popular custom of exchanging picture cards; few of them kept albums at this time. But the postcard craze of the 1890s and early 1900s did come to their attention. In 1909 the postcard trade in New Zealand reached its peak—nine million cards passed through the postal system in a country with a population of just one million. Europeans liked to send cards to fam-

Auckland Institute and Museum

ily and friends—especially picturesque or amusing cards—and the popularity of Maori images required many models. These models were photographed in contexts that bore little or no relation to the manner in which they actually lived.

The most popular cards were of old-time Maori, nostalgically depicted as the last in a line of noble warriors or priests; re-enactments of pre-European Maori scenes in spurious period costumes; scenes of Maori rural idylls that aped those of the London photographic salons of the time; and portraits of sexually alluring maidens, cute Cupid-like naked children, and madonna-like Maori women carrying infants. Also popular were cards that, like some American postcards with Negro subjects during the same period, portrayed Maori as simple folk, unable to cope with the complexities of Western civilization.

All these pictures were more telling reflections of contemporary European attitudes than of Maori life. And while some Maori felt that the Europeans who took such photographs were themselves made to look extremely foolish, most believed such pictures demeaned Maori and Maori culture. Other Maori feared the commercialization of the images. If they were sold for money, they would lose their sacredness. Some of these attitudes toward photography persist today but are likely to be modified by the gradual emergence of Maori photographers who are sensitive to Maori views and fears about photography.

Most photographs of Maori in New Zealand, however, were taken by non-Maori. By that fact they become culturally loaded statements. The very presence of a camera operated by a European affected and altered the appearance, arrangements, and behavior of those being photographed. Inevitably the values and the beliefs of the photographers and the conventions of European art and photography affected the presentation of Maori in photographs. Some activities central to the day-to-day workings of Maori communal life are entirely absent because they did not fit notions of what was photogenic, because they would not represent Maori in contexts that a non-Maori audience would recognize, or because it would have been technically difficult to record them. In the early days of the medium it was necessary to photograph people standing absolutely still for long exposures, and outdoor pictures were always easier to take than indoor ones; consequently there are few interiors among the older prints.

These factors often combined to make historical photographs as concealing as they are revealing. They show selected public moments in Maori lives as arranged by the photographer. There is a plethora of nineteenth-century pictures of Maori standing outside their dwellings, often in their most formal clothing. Sometimes the prints include odds and ends that hint at the technology of the subjects' lives—kettles, cooking fires, blankets—and sometimes domestic animals and toys. To learn about the more intimate aspects of Maori lives, however, how much one would like to see *inside* their dwellings, and to see *them* inside—preparing food, eating, drinking, talking, sleeping, waking. And how much one welcomes the few photographs in which people seem alive rather than statuesque. The greatest cause for regret, perhaps, is that in the earlier years there were no Maori photographers who might have taken such pictures unobtrusively. □

Portraits of alluring maidens with such titles as A Maori Belle, *right, were the most popular category in the postcard trade. Commercial photographers at the turn of the century kept a wide range of these pictures on hand.*

The Accord 4-Door Sedans

To El Chichón and Back

On an expedition to southern Mexico, scientists sift through the ashes of a deadly volcanic eruption

by Haraldur Sigurdsson and David Gardella

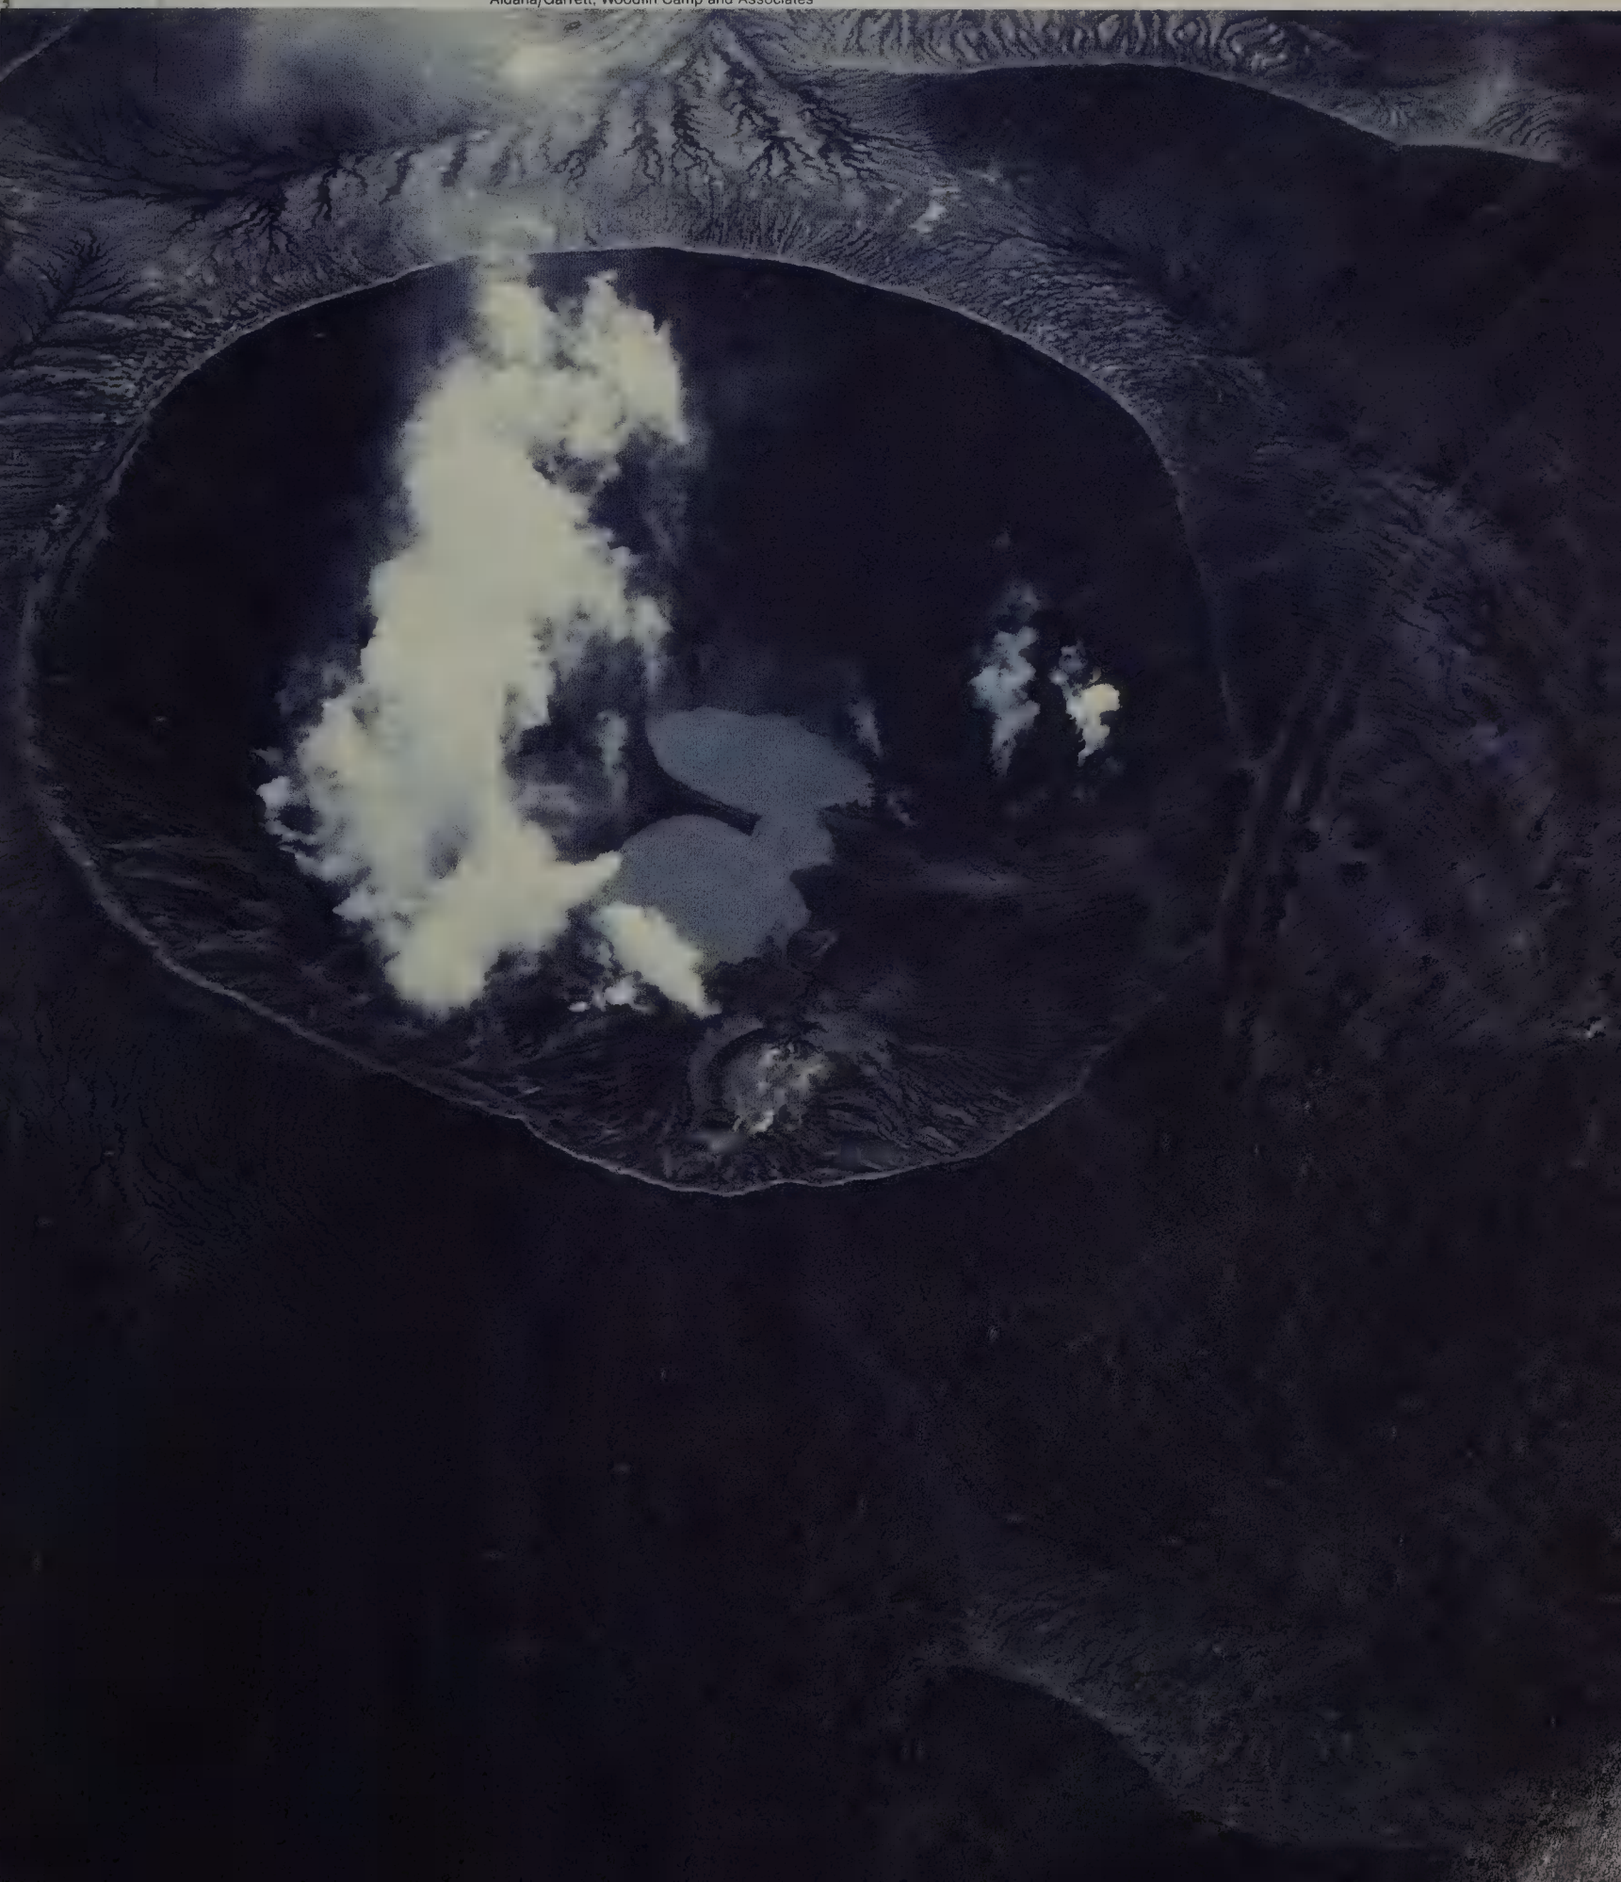
A little more than three years ago, El Chichón was a harmless-looking mountain in southern Mexico, covered with tropical forest. As a volcano it was obscure; certainly no one considered El Chichón a hazard. But early in March 1982, ominous readings began to appear on seismic instruments. The earth's vibrations were not strong enough to be felt, but late in the month they increased sharply, and on March 28 an explosive eruption broke out. Pumice and ash rained down on the surrounding towns and villages, caving in roofs as far away as Pichucalco, a distance of twenty-five miles.

Injury was light after this first eruption but the local Zoque Indian population became agitated. Churches were packed, and town officials blamed the alcohol-induced, sinful ways of the people for bringing down God's vengeance. Over the next few days, as small explosions were observed by eyewitnesses, recorded by seismic stations, and captured on satellite images of the region, scientists from the National University of Mexico began studying the newly active volcano. While researchers sought to assess the extent of further hazard, the Mexican army was mobilized to supervise evacuation and control access to the danger zone. The evacuation was slowly getting under way when army personnel and civilians alike were surprised by a second major eruption on the night of April 3. This time the force of the eruption was devastating, sweeping down the forest up to five miles from the crater and destroying nine villages. Approximately 2,000 people were killed.

The following day, April 4, saw the longest and final eruption, but by then many of the local inhabitants were dead. Thousands of head of cattle and all other forms of life in the area had also been exterminated. A huge cloud from the eruption spread rapidly westward at an altitude of sixteen miles and encircled the globe in twenty-one days. Direct sampling of this stratospheric layer by aircraft and balloons, as well as satellite studies, indicated a very high content of sulfur, which in combination with atmospheric water vapor formed a sulfuric acid aerosol. No other volcano had made such an impact on

An aerial view of El Chichón, taken several months after the April 1982 eruption, shows the sharp-rimmed crater from the southwest. Partly obscured by volcanic deposits, the irregular outline of a prehistoric crater, created by a large eruption about A.D. 1400, surrounds the new crater.

Aldana/Garrett; Woodfin Camp and Associates



the earth's stratosphere in the past twenty years, and several scientists predicted that the consequence would be a cooling trend at the earth's surface—a reverse greenhouse effect.

In June, shortly after the 1982 eruptions, we mounted our first expedition to El Chichón, which is located in the Mexican state of Chiapas. Seismic activity had ceased, but entry into the blast zone around the volcano was still highly restricted. Our interest was twofold: to determine the volcanic processes that had caused local destruction, and to study the geochemistry and mineralogy of the magma (molten rock) that had produced the sulfur-rich stratospheric aerosol veil. When we arrived, we found the area nearest the volcano still impassable. Some deposits of volcanic material were too hot to walk on, and the steady flow of volcanic gases from them made conditions almost unbearable.

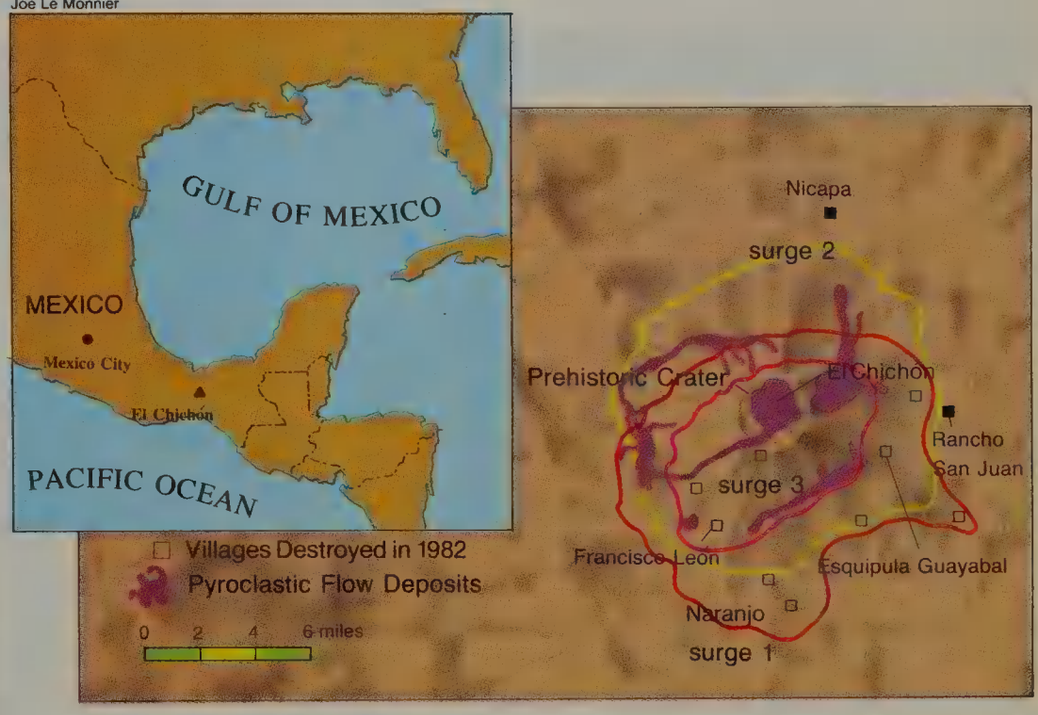
For the most part we were forced to limit our survey to the outlying ashfall, but we did learn one important thing from our closer observations: among the events that caused the devastation were pyroclastic surges and flows. A pyroclastic surge is a highly turbulent, hurricane-like avalanche of hot volcanic ash and pumice mixed with air and volcanic gases. Surges are often accompanied by pyroclastic flows, which are denser mixtures of hot ash and pumice that flow along valleys and riverbeds. We were eager to examine these violent processes, partly because they are believed to have figured prominently in the eruption of Vesuvius in A.D. 79. Our preliminary studies showed that within a five-mile radius of El Chichón, hot surge clouds, at temperatures of up to 800 degrees Fahrenheit, had blasted along the earth's surface with the force of a nuclear explosion. Fragments of rock, volcanic ash, and pumice were swept along at sixty miles per hour. Our interest aroused by these observations, we decided to let the area cool off for a while and planned a second expedition in January 1983.

On our return to southern Mexico, a Cessna airplane made three trips to take us and the other participating geologists (Steven Carey, Richard Fisher, and Juan-

Chris Johns; Seattle Times, Black Star

Left: El Chichón spews its sulfur-rich ash. The final and longest eruption was on April 4, when the plume reached stratospheric heights. Below: Nine villages were destroyed on the night of April 3 by a hurricane-like avalanche of hot ash and volcanic gases, known as a pyroclastic surge (Surge 1 on the map). This and a second surge were part of El Chichón's most violent eruption. The blasts were accompanied by outpourings of denser materials, called pyroclastic flows. The eruption on the following day included a third, smaller surge.

Joe Le Monnier



Manuel Espindola), along with our supplies, from the village of Pichucalco to the periphery of the sixty-square-mile area devastated nine months before. As we flew the twenty miles westward toward the volcano, we saw a knife-sharp boundary between the tropical forest and the barren, gray, ash-covered blast zone. There, about five miles from the crater, was the deserted ranch—El Rancho San Juan—that would become our base for five weeks.

The nearest inhabited village was Chapultenango, three miles to our east. Just outside this village, on the winding mountain footpath leading to our ranch, was a sign marking the restricted zone: *Peligro Volcán* (Danger Volcano). Westward from the ranch toward the volcano, the land was covered with bone-colored volcanic ash; it was devoid of all life except for the droning of insects. But in the opposite direction, the hills and mountains were resplendent with banana plants and other lush green foliage, and the sounds of birds and croaking frogs filled the air.

We spent the next day shoveling ash out of the ranch house, the headquarters from which we would launch daily forays to the volcano. The once beautiful green expanse of Rancho San Juan was now under twelve to sixteen inches of pumice and ash. Next to the ranch house were two battered Cessnas, which looked as if they had been riddled by machine gun fire. Their fuselages and wings had been perforated by falling stone projectiles during the first eruption, on March 28. Near the planes were the remains of a truck, facing away from the volcano. The paint on the front was unscarred, but the taillights were melted and the tires were burst by the heat of a pyroclastic surge. The surge had come to a halt only seventy feet from the ranch on April 3, killing many cattle.

Three days after our arrival, we set out on our first climb to the rim of El Chichón's new crater, which is nestled within a larger, prehistoric crater. After an hour's hike along a sulfurous stream, we reached the foothills of the volcano. Crossing a barren plain of pyroclastic flows, dotted with fumaroles venting hot steam, we ascended through steep and recently eroded canyons to the outer crater rim. We then confronted a wide moat, crisscrossed by a network of steep, narrow canyons. After tackling these badlands, we approached the new crater rim, the roar of fumaroles sounding ever louder. Finally, we scrambled up to the sharp rim and peered into the crater. About six hundred feet below was a hot lake of bright lime green, with sulfurous bands decorat-

Ash from El Chichón's April 4 eruption darkens the late afternoon sky in San Cristóbal de las Casas, eighty miles southeast of the volcano. Residents seeking to stock up on goods are admitted one at a time to a local supermarket.

Aldana/Garrett; Woodfin Camp and Associates

ing its edges. From the floor and walls of the half-mile-wide crater, hundreds of fumaroles spouted steam, fumes, and noxious volcanic gases. We began our mapping at the crater rim.

Our fieldwork involved identifying the volcanic deposits left by each eruption, mapping out their distribution, and measuring their thickness at different locations on the landscape. We also collected samples of the deposits for laboratory study of particle size and geochemistry. Basically, there were three kinds of deposits. The most widespread consisted of ash and pumice that had settled as fallout from the air (ash and pumice are distinguished simply by particle size—ash is the finer material). From the characteristics and distribution of particles in such deposits, we can learn various things about an eruption, such as its force and duration, the height of the column, and the wind conditions that prevailed when it occurred. In addition to the fallout layers there were debris flows fifteen to thirty feet thick, consisting of jumbled blocks and rock fragments of the old volcanic structure, and deposits that we identified as coming from pyroclastic surges and flows. There were no lava flows, which result from the extrusion of magma in a liquid state. Lava is formed only when the magma does not contain high concentrations of volatile compounds, such as water. At El Chichón, all the eruptions had been violent.

After a week's stay at the ranch we had completed geologic mapping of the deposits on the east side of the volcano, and it was time to move camp. Our next goal was the village of Francisco León on the south flank of the volcano. A geologist and a group of soldiers, along with a number of Indian villagers, had lost their lives there on April 3 in the blast of a hot surge cloud.

We arose early in the morning and made final preparations to leave Rancho San Juan for a five-day excursion through the forbidding blast zone. Two Indians from Chapultenango arrived leading four scrawny mules, and soon our mule train was under way. Since there were no trails, we picked our own route along valleys and gullies. After about an hour's trek, we reached a hill designated on the topographic maps as the site of the village of Esquipula Guayabal, about two and one-half miles southeast of the volcano. It was hard to imagine that under those barren gray dunes a village had thrived nine months before. Finally we found tangible evidence—two bent steel posts protruded from the ash, the supports for the nets in the village school basketball court. No other trace of the village showed above the three-foot-thick blanket of surge deposits.

From the Guayabal hill we looked ten miles down a long, bleak river valley toward Francisco León. Volcanic deposits had altered the valley topography, influencing the river's flow. Our passage along the narrow riverbanks was difficult, and often the easiest path was the river itself. Finally, we rounded a bend in the river and saw the broken stone walls of a church, precariously undercut by the rerouted river. These thick walls were the only village structures still standing. As we crossed through the leveled settlement,

llagers in Nicapa, north of the volcano, escaped the reach of the pyroclastic surges, t ashfall caved in rooftops. The village church and central square are at the top of e aerial photograph.

ana/Garrett; Woodfin Camp and Associates

e spotted traces of domestic life—pans, gs, a rusted machete, and a pair of scis-rs sticking out of the ash. We made our amp at a respectful distance from the dden remains of those who had been as-nyxiated by the surge cloud.

To the south was the green rain forest, hile the blast zone spread north to the olcano, four miles away. The blast zone as barren except for a few clumps of rass and some insects, especially dragon-es and butterflies. Fortunately, mosqui-es were virtually absent, perhaps be-ause the streams and ponds were acid-ed by sulfur that had leached out of the volcanic ash. All that remained of trees were scorched, broken stumps, but large-leafed elephant ear plants and tall grasses were making a comeback as close as two and one-half miles from the crater. Nature was less bleak at the edge of the blast zone, where vines and other greenery were creeping out of the forest. Here we spotted two killdeers, as well as small fish in the streams, and frogs and lizards appeared at our swimming hole. A few egrets and herons lived off the other wildlife. An ominous presence was a hungry pack of dogs that roamed the hills around El Chichón in search of food.

Every day we left our camp near the desolate ruins of Francisco León and mounted expeditions up the flanks of the volcano. After one week we were nearly ready to return to Rancho San Juan, but one task remained: a survey of the destroyed town of Naranjo, about five miles from the volcano and at the very edge of the blast zone. A study of the site would give us valuable information on the effects at the farthest end of the surge.

Naranjo is situated on a pedestal-like plateau, with a splendid view of the volcano in the distance. As we hiked onto the plateau, the town suddenly came into view. Many masonry structures were still standing, including the church, but the surge cloud had stripped other buildings of their roofs, thatched siding, and corrugated iron. All that was left of them were the carbonized wood corner posts, bent slightly away from the source of the blast. Cinder block buildings were damaged, generally with the walls broadside to the volcano caved in completely. The level of destruction surprised us, since the deposit from the surge was only about one to two inches thick on the ground. As we wandered through the eerie ghost town, which once included a modern hospital, we came upon the skeletons of several of its inhabitants, inexplicably scattered about on the surface of the volcanic ash. These bones, we discovered, originated from trenches dug in the ruins of several of the shacks and houses in the town. Looters had explored Naranjo before us and treated with utter contempt the remains of any victims they encountered. We found ourselves faced with the depressing task of gathering up the bones and burying them near the ruins of the church.

In the course of our investigations of the new volcanic deposits, we found evidence of the volcano's earlier history. The oldest deposits have been dated by the potassium-argon method to about 200,000 years ago, making El Chichón relatively young as volcanoes go. Four additional ancient episodes of activity could be discerned. One remains undated; the others have been dated by the carbon-14 method to roughly A.D. 400, 850, and 1400. This last eruption, which was an order of mag-

Because El Chichón's first eruption spurred a voluntary evacuation, many villagers living near the volcano survived. But the most violent eruption took about 2,000 lives.

nitude greater than El Chichón's eruption in 1982, created the large prehistoric crater that surrounds the new crater. Before leaving southern Mexico, we also sampled distant ashfall from El Chichón. This took us to the Yucatan and Palenque, the location of spectacular temples of the vanished Maya culture.

Our study of the volcanic deposits in the ruins of Naranjo, Francisco León, and elsewhere around the volcano provided us with evidence to reconstruct the series of eruptions of El Chichón in 1982. All three of the major events—the first eruption of March 28 and the last two, on the night of April 3 and the morning of April 4—had left tangible evidence. The last of the intervening minor explosions, which occurred on the morning of April 3, also left a trace, a minor fallout layer that included small mud balls known as accretionary lapilli. These are evidence of an explosion caused by ground water coming into contact with magma.

One of our most important observations was that the particles in the next-to-uppermost fallout layer were the coarsest; this indicated an especially energetic eruption with high output per unit of time. This layer was sandwiched between two pyro-

clastic surge deposits. Two pyroclastic flows, each six to twenty feet thick, as well as the debris flows, formed adjacent layers. The association of all these deposits with the fallout from this one eruption gave further testimony to its violence. A third, smaller surge deposit rested on top of the uppermost fallout deposit.

Using this kind of field evidence, in conjunction with what was known from eye-

Naranjo, about five miles south of El Chichón, was destroyed on the night of April 3 by the first pyroclastic surge. Although the town was at the edge of the blast zone, charred corner posts, bent away from the volcano, are all that remain of many buildings.

Aldana/Garrett; Woodfin Camp and Associates

witness accounts, seismic recordings, and observations from satellite images, we reconstructed the following scenario. The first eruption, on March 28, was what is called a Plinian eruption—a steady, high, fountainlike discharge of pumice and ash. In a Plinian eruption, the volcano ejects a sustained jet of fragmented magma; this jet draws in and mixes with atmospheric air, which is heated and expands, acting to lift the column in a convecting plume. El Chichón's first eruption behaved in this way, sending up an eruption column at least eleven miles high. The fallout of volcanic ash and pumice was deposited in a thin layer over southern Mexico and had little effect except locally, where it was thick enough to cause roofs to collapse and (fortunately) to spur a voluntary evacuation of many residents.

The first eruption punched a hole through the old volcanic dome at the summit of El Chichón. Over the next several days, ground water came into contact with the hot magma (about 1600 degrees Fahrenheit), causing explosions known as phraetic eruptions. The weak explosion on the morning of April 3, which left minor ashfall, was one such explosion.

The most violent eruption, on the evening of April 3, led to total destruction of the domelike summit of the volcano. This complex event proceeded in three stages. At first, the eruption column did not assume Plinian form; convective currents failed to lift the eruption plume. This may happen for various reasons, but in this case it was probably because the crater had been excessively enlarged or because the high rate of eruption prevented sufficient intermixing of air. Instead, there was a pyroclastic surge and flow, as the burden of volcanic material avalanched down the flanks of the volcano. This was the first devastating event during the series of eruptions and led to the destruction of the nine villages around El Chichón and the blowdown of the forests. Subsequently, the column gained buoyancy, and the eruption plume rose to stratospheric heights, with fallout of ash and pumice producing a thin deposit on top of the first surge layer. Within hours, the eruption column collapsed again, producing a second pyroclastic surge and flow similar to the first. This time, however, the surge spread over a lifeless, barren volcanic surface, except to the north, where it extended several miles beyond the edge of the first surge zone, stopping short of the town of Nicapa. Repeated collapses of an eruption column similar to this are believed to have been responsible for much of the destruction of Pompeii and Hercu-

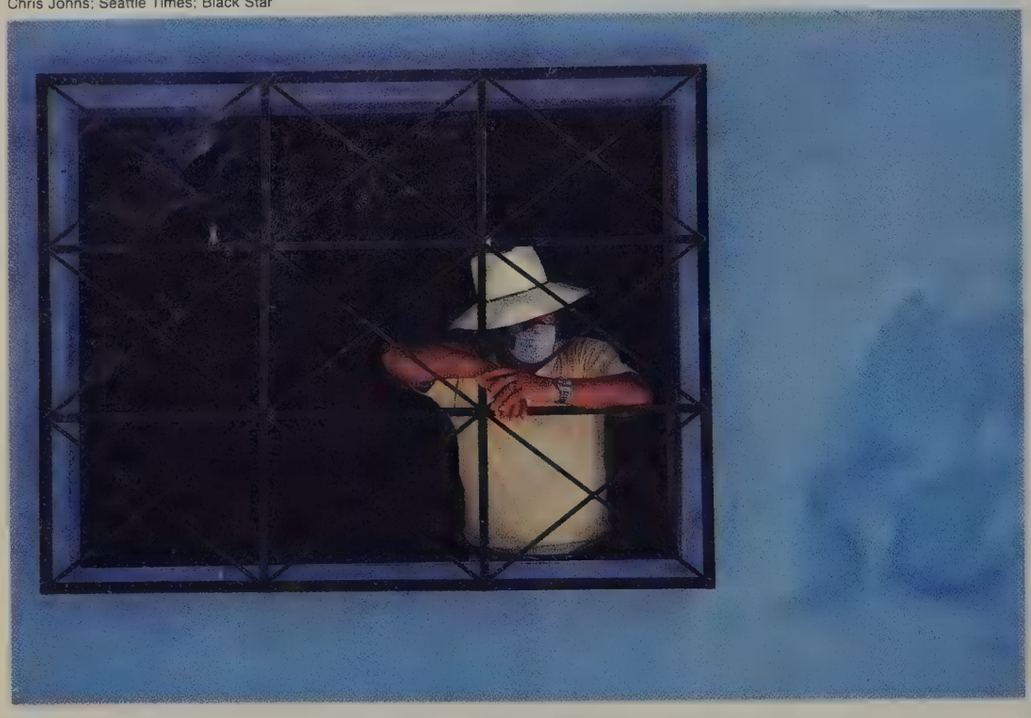
Chris Johns; Seattle Times; Black Star



laneum during the eruption of Vesuvius.

The final explosive eruption was early the next morning, April 4. Although less energetic than the one that preceded it, this event lasted the longest and produced a column that may have extended to a height of sixteen miles. The eruption column was sustained and produced fallout of ash and pumice in large quantities until its final stages, when it collapsed, generating a small pyroclastic surge.

The sulfuric acid veil El Chichón created in the stratosphere, especially with this last eruption, received worldwide attention. When we returned to our laboratory at the University of Rhode Island, we began analysis of our samples of pumice and ash in an effort to explain the origin of the sulfur. We expected to find that the magma simply had a very high sulfur content, but much to our surprise, it contained only modest amounts of dissolved sulfur. Instead it contained anhydrite, a sulfur-rich mineral that is exceedingly rare in volcanic rocks. Apparently the breakdown of this mineral during the eruptions resulted in the massive release of sulfur gases to the atmosphere.

Fortuitously, El Chichón is close to some oil wells, and bore holes have yielded information about the geologic strata down to a depth of about two and one-half miles. At that depth there is a layer of evaporites, sediments left when seawater evaporated some one hundred million years ago. The sediments include, in addition to ordinary salt, a considerable amount of anhydrite. Although other explanations are possible, the volcanic magma most likely stewed in a reservoir enclosed in part by this sedimentary layer, and thus became saturated with sulfur.

In all, about ten million tons of sulfuric acid aerosol were injected into the stratosphere, forming a layer thirteen to sixteen miles above the earth. Since this layer backscatters incoming solar radiation and absorbs infrared radiation, many scientists predicted that the stratosphere would warm up and that this heat would be lost to us down here on the earth's surface. No volcano had injected such large quantities of volcanic aerosol since the Agung eruption in Bali, Indonesia, in 1963. During the year following that event, the earth's surface cooled about one degree Fahrenheit throughout the entire Northern Hemisphere.

Sufficient time has now elapsed to evaluate the possible atmospheric effects of El Chichón. In April 1982, almost immediately after the eruption, the earth's stratosphere at the level of the El Chichón aerosol layer became up to nine degrees Fahrenheit warmer. This strong effect, however, was later shown to have been partly due to a periodic change in stratospheric temperature, which happened to coincide with the eruption. Actual stratospheric warming caused by the eruption was estimated at no more than five degrees Fahrenheit. Did this warming result in noticeable heat loss at our planet's surface? Calculations showed that this should have been the case, but no surface temperature change was observed in the tropics. In north temperate latitudes, temperatures actually increased substantially—almost five degrees Fahrenheit above average—and global surface warming occurred immediately after the eruption.

The explanation for this paradox came when scientists realized that an intensification of the warm equatorial Pacific ocean current had coincided exactly with the El Chichón eruption, and its effect had more than canceled out the predicted surface cooling. This warming in the eastern Pacific, which occurs at rather irregular intervals, is called El Niño because of its association with the Christmas season. Its causes are mysterious, but it does affect surface temperatures in the tropics. Compared to previous events, the sea-surface temperature warming in the spring of 1982 has been called the "El Niño of the century." Scientists are still debating whether the veil of volcanic dust that El Chichón spread over the equatorial Pacific induced this strong El Niño.

Recent studies show that in addition to sulfurous material, the eruptions in 1982 also injected 40,000 tons of hydrogen chloride into the stratosphere, increasing the presence of that gas by 40 percent. This development could be of some concern because chlorine gases break down the ozone layer, the earth's principal shield against harmful radiation from the cosmos. Whatever its long-term effects may prove to be, however, El Chichón reminds us of the intrinsic differences in geochemistry among individual volcanoes. Although comparable in terms of total erupted mass and magnitude, El Chichón released about two hundred times more sulfur to the earth's atmosphere than the celebrated 1980 eruption of Mount St. Helens. □

Stowaways on the Hummingbird Express

Nectar-sipping mites that hitch rides on hummingbirds are very choosy about where to get off

by Robert K. Colwell

To our eyes, the red and orange flowers of hummingbird-pollinated plants stand out in the deep shade of the rain forest like rubies on green velvet. To hummingbirds—whose range of color vision is even greater than ours—the contrast must be just as striking. But the rich world of odors is closed to hummingbirds, and our own poor olfactory equipment is little better.

The perennial human daydream to fly like a bird surely has its roots, in part, in the similarity of our sensory worlds. Who would not welcome the chance to be a tropical hummingbird for a day, given proper training? The exhilaration of fast and agile flight, the high-calorie diet, the beauty of the forest—all this we can envy and imagine.

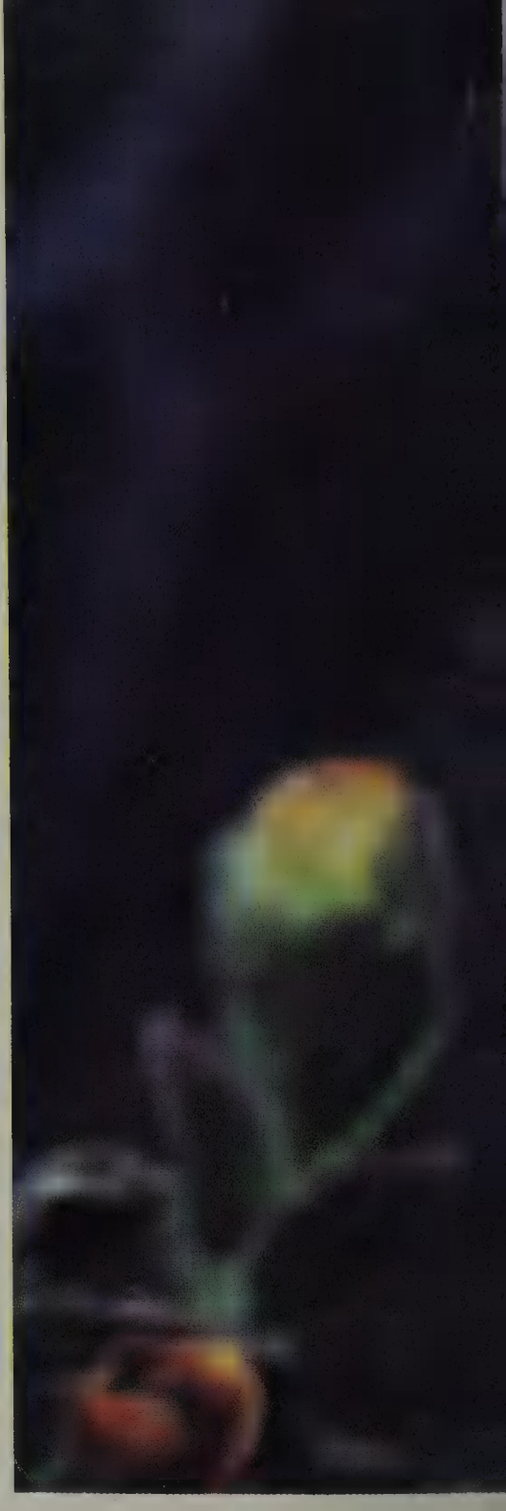
But now enter the same world on a different scale. Imagine yourself a mite just twice the size of the period at the end of this sentence. You are having a breakfast of nectar and pollen with your family and neighbors inside the orange-red, inch-long flower of a *Hamelia* plant at the edge of a rain forest clearing. You have no eyes and need none, because your four pairs of legs and your body are equipped with precisely arranged, minute hairs, called setae, that provide exact information about your special world. When you meet another mite in your flower, a quick touch with your foreleg tells you its sex and age, and the rate of encounter tells you how many other mites share your flower. You can even "smell" with some very special setae on the tips of your forelegs. Although neither hummingbirds nor humans can smell your flower, it has a distinct and very important fragrance for you. It smells like home, and home means safety, your own kind, mates, and food.

Suddenly you sense the vibrant approach of a hummingbird outside the flower. A half second later a bill sixty times the length of your body is thrust deep into your home and you must dodge the rapidly licking tongue that is draining your larder. In the one to five seconds before the hummingbird leaves for the next flower, you must make a decision that will affect the rest of your life. What are the future prospects for food, mates, and the welfare of your offspring on this branch of this *Hamelia* plant, compared with the chance that a risky journey will turn up better prospects elsewhere?

If you decide to leave, you dash up the bill of the visiting hummingbird and run into its nostril, and the odyssey begins. On board, inside the bird's nasal cavity, the accommodations are primitive. There is nothing to eat or drink. The place is crawling not only with your own kind but also with aliens of other species of hummingbird flower mites, hitching rides to their own promised land. You will know them by their smell, perhaps, and by the strange arrangement of their setae—long where yours are short, straight where yours are so beautifully curved.

But the ventilation on this feathered freighter is absolutely first-class. A hundred times every minute or so, a hurricane of fresh air rushes in. More than just a source of oxygen, the hummingbird's respiration acts as an odor pump, constantly updating information on the outside world. What you await is that familiar smell—the odor of your own host plant,

David S. Dobkin



Mites that live only in hummingbird-pollinated flowers travel to distant blossoms by climbing on a bird's bill and taking shelter in its nostrils. Below: A Rhinoseius colwelli *mite crouches within a bird's nostril while another stands by. Right: This California species of Indian paintbrush supports a contingent of* R. epoecus *mites, a species discovered recently.*

Shahid Naeem

Hamelia. The hummingbird may visit the flowers of half a dozen other plant species, and the aliens on board may come and go, but you wait until the scent of *Hamelia* tells you the bird has its bill in the flower. You have one to five seconds to disembark. With luck, if you are a male, you will find females in need of a mate in your new home; if you are a mated female, you will find that a nearly empty flower, with a male or two present to replenish your supply of sperm, would be an ideal place to start your own dynasty.

A primary research journal would probably scorn the shamelessly dramatic account you have just read. Yet every good naturalist learns to "see into the life of things," as Darwin put it, in part by identifying with the organisms studied. Even botanists do it. The danger, of course (and the reason for the taboo on exposing such musings in scientific print), is that we may unwittingly and inappropriately impose human capabilities, limitations, or even values on nonhuman organisms. For example, a mite certainly makes a "decision" in a very different sense than we do.

Fortunately, our understanding of the biology of hummingbird flower mites rests on more than daydreams. I first stumbled on the existence of these mites and guessed their relationship with flowers and hummingbirds in 1969 in the Costa Rican highlands. In succeeding years, the project that began at that time broadened geographically and scientifically as my colleagues and I developed new techniques of study and a deeper understanding of the daily lives of hummingbird flower mites. Peter Feinsinger, of the University of Florida, an authority on tropical hummingbirds, has collaborated generously, and my doctoral students, David Dobkin, Amy Heyneman, and Shahid Naeem, have poked their own noses into the flowers of *Hamelia* and other hummingbird plants in intensive field research in California, Mexico, Costa Rica, and Trinidad. Barry OConnor, of the University of Michigan, has scientifically described and named many of the new mite species we have found.

Hummingbird flower mites are freeloaders. As far as we can tell, they do nothing of note for their host plants or for hummingbirds. Yet their survival depends on the interdependence of birds and flowers, which are mutually linked by the exchange of nectar for pollination service. A closer look at hummingbirds and plants reveals the way this network operates.

Within the limits of a very consistent body plan and behavioral repertoire, the more than three hundred species of hummingbirds present an astonishing diversity of body size, coloration, plumage, and bill shape and length. They are strictly a New World group, with outlying species found, at least during the breeding season, from Alaska to Tierra del Fuego. A few acres of tropical forest can contain a dozen or more abundant hummingbird species. The plant species that hummingbirds pollinate number in the thousands and represent dozens of plant families.

Hummingbird flower mites are found nearly everywhere there are hummingbirds. So far, we have recorded the mites from more than one hundred host plant species and from more than sixty hummingbird species, and these records represent only very spotty coverage of the range of hummingbirds. But even where the mites have been studied, not every species of hummingbird-visited plant supports them. Hummingbird-pollinated species in some plant families never have these mites (for example, the mallow, mint, and fuchsia families), and some nearly always do (tropical species in the lobelia, blueberry, and many other families).

Hummingbird flower mites belong to two closely related groups, the genus *Rhinoseius* and a large lineage within the genus *Proctolaelaps*. The dozens of species we have studied so far are nearly all new to science; one or two hundred species are perhaps still undiscovered. As far as we know, only one species resides seasonally in the United States. This *Rhinoseius* mite summers along the California coast in the flowers of Indian paintbrush (*Castilleja*). It spends the winter in the mountains of west-central Mexico with California migrant hummingbirds and in recent times, in the flowers of African aloes in central California gardens. Shahid Naeem and I have named the species *epoecus*, from the Greek meaning "a sojourner from a foreign land." The greatest diversity of hummingbird flower mites is in lowland tropical forests, where a dozen or more species often share an acre.

Hummingbird flower mites are very discriminating in regard to their host plants. In the lowland tropics, each species

ypically occupies only a single host plant pecies, which blooms all year. By contrast, mite species at high elevations and igh latitudes, where flowering is more easonal and less reliable, usually have a hoice of two or more host species that hey often use sequentially. In most cases here is only one species of hummingbird lower mite per plant species, but in a few ases there are two—always a *Rhinoseius* pecies and a *Proctolaelaps* species, never wo species of the same mite genus.

Host plant species differ strikingly in easonal flowering pattern, the size and arangement of flowers, the amount of nectar each flower produces, and the longevty of each flower (half a day to more than week). These differences in host plant bilogy profoundly affect the mites.

Life begins for a hummingbird flower mite as an egg nearly one-fourth the volume of its mother's body. (Nonetheless, she can produce half a dozen eggs in a few hours.) Some species whose host plants have long-lived flowers lay their eggs right in the nectary of the flower, where they are bathed in nectar for a few days until they hatch. Mites that live on plants whose flowers open in the morning and drop later the same day lay their eggs among bracts or beneath leaves near the flowers. The eggs hatch into active six-legged larvae; this stage is quickly followed by two active eight-legged nymphal stages that precede adulthood. The mite goes from egg to breeding adult in about a week.

While it is easy to find mites by cutting open their host flowers, it is hard to watch them within the bloom unobtrusively. Fortunately, as long as they have their flowers, even on a cut branch in a vase of water, they seem not to notice being moved into the field laboratory for scrutiny. With a fiber-optic light, which produces intense light but very little heat, we can illuminate their miniature world for study with a dissecting microscope, apparently without disrupting them. Most of the behavior we observe in this way is repeated in glass capillary tubes with nectar.

The inside of a tubular flower is a fairly complicated place. Adult mites tend to congregate near the nectaries, in the base of the flower in most species, while the nymphs and larvae spend more time on the stamens and style. During all these stages the mites drink nectar, which contains proteins, fats, and amino acids, as well as sugars.

Proctolaelaps kirmsei adults avidly

Although imperceptible to humans and hummingbirds, the scent of a host plant, such as Hamelia patens, *below, prompts mites on a bird's bill to disembark. In field and laboratory, mites consistently recognize the odor of the host plant and prefer its nectar to equally nourishing substitutes.* Centropogon cornutus *produces exceptionally long-lived flowers, right. While other mites must lay their eggs on the leaves or bracts of their host plants, those that live on* Centropogon *lay eggs in the nectar, and the young hatch and mature within the blossom itself in a week's time.*

Robert K. Colwell

"process" pollen grains for a short period after entering a new flower of their host plant, *Hamelia patens*. The flowers of this plant open shortly after midnight (at least in Costa Rica), long before its pollinators become active at dawn. The mites rush in as soon as the flower opens. They immediately begin a frenzied attack on the pollen packed in the anther sacs, using a pair of short appendages to move one grain at a time over their mouthparts. We suspect that the mites are removing nutritious substances that coat the pollen grains. In terms of relative size, it would be as if you had before you a large bin of basketballs covered with peanut butter and honey, which you picked up one by one to lick.

When an individual flower has fully bloomed, the mites are able to leave it on foot to lurk about the same flower cluster until the next flower opens. Passage between clusters, however, seems usually to require the unwitting assistance of a hummingbird. In field experiments, uninhabited flower heads closed to mite foot traffic but exposed to hummingbirds are quickly populated by mites.

Hitching a ride on a hummingbird requires timing and agility. Taking the length of the mite as two-hundredths of an inch (some species are smaller), the bill length of the bird as about one and a quarter inches (some are longer), and allowing a generous five-second feeding visit by the bird, the mite must run as fast as a cheetah, for its size, to make it into the nostril before the bird moves on. (In other words, both hummingbird flower mites and cheetahs can run about twelve body lengths per second. We have actually clocked the mites at this speed in wind sprints around the lip of a test tube.)

"Deplaning" presents new difficulties. Before racing down the bill into a flower, the mites must first determine whether or not the flower is of their own host species. Our records for many thousands of mites show that no more than one in two hundred has disembarked in the wrong flower. Yet many hummingbirds visit several species of plants in an hour's time, and often each plant has its own species of hummingbird flower mite. How do they know when to get off?

By far the most likely source of information is odor. With the bird's bill in a flower, mites in the bird's nostrils could quickly determine the species of the flower and act accordingly, based on odors provided by the bird's rapid respiration.

Robert K. Colwell

Our evidence is indirect but convincing. Given a choice of nectars in a T chamber, hummingbird flower mites choose nectar from their own host plant species. In Trinidad, for example, we offered the mite *Proctolaelaps kirmsii,* which lives in the flowers of *Hamelia patens,* a choice between nectar from uninhabited flowers of *Hamelia* and equally "virgin" nectar from flowers of *Centropogon cornutus,* the home of another mite. We put a drop of *Hamelia* nectar in the tip of a tiny glass capillary tube and a drop of *Centropogon* nectar in another. The open ends of the two tubes lead into an enclosed three-way "intersection" in a small block of acrylic. The third entrance to the intersection (the leg of the T) is another capillary tube with a mite from *Hamelia* in it. Twenty identical chambers were simultaneously set up. We kept track of the location of each mite in its chamber over a period of hours.

The mites in this experiment strongly preferred the nectar of their natural host plant—nearly all of them ended up in the tubes with *Hamelia* nectar, rather than in the tubes with "alien" *Centropogon* nectar. But when we put mites from *Centropogon* (another species, *Proctolaelaps glaucis*) in the same setup, they preferred *Centropogon* to *Hamelia* nectar. The mites are even more consistent in nature, where they are presented with one host plant odor at a time in a moving stream of air rather than two odors in still air.

Many species of hummingbird flower mites from Trinidad, Mexico, Costa Rica, and California have participated in our T-chamber experiments. A consistent pattern emerges. Each species prefers its own host nectar to the nectar of other species of mite plants. The mites also choose their own host nectar over sugar water of the same concentration and over nectar from miteless plants, that is, hummingbird-visited species that never support hummingbird flower mites. Amy Heyneman, who has analyzed dozens of nectars from both kinds of plants, has found biochemical differences between the two groups of nectars. Our field experiments, however, show that, within broad limits, the host nectar of one mite species is nutritionally acceptable to other mite species in the same habitat. We forced mites to live in newly opened, unoccupied host flowers of a plant normally inhabited by another mite species. A nylon mesh bag excluded hummingbirds and thereby prevented escape of the mites, many of which survived to reproduce successfully.

Why, then, are the mites so particular about the host plants they actually use? If every flower were densely populated with mites, competition among mite species for nectar might explain the adherence of each mite species to certain host plant species. However, the density of mites is quite low, relative to the nectar available, so competition between mite species is not a likely explanation for the very rigid plant–mite affiliation. Another possible explanation is that each mite species aggressively excludes "aliens" from its host plant. But most pairs of mite species get along quite amicably in laboratory tests. Moreover, certain pairs of species share the same host plant on a regular basis.

The explanation I favor for host allegiance is that hummingbird flower mites use host plants as a way of finding mates. Once a particular host plant species becomes the most popular jumping-off place for a given mite species, the mating success of mites that get off elsewhere will suffer, on average. Because in these species both males and females must mate many times to achieve their maximum reproductive potential, mites of either sex that disembark at the correct host plant will leave more descendants.

If I am right in thinking that plant affiliation evolved among hummingbird flower mites in large part through differences in

mating success, then host affiliation can be viewed as the product of sexual selection. Darwin first drew the important distinction between evolutionary changes based on inherited differences in survival rate and in the potential for reproduction, the process he called natural selection, and evolutionary changes based on differences in mating success in itself, a phenomenon he termed sexual selection.

Darwin believed that natural selection and sexual selection could, at times, conflict. Some physical and behavioral traits of animals are thought to have evolved largely through their role in courtship and mating, perhaps even at the cost of decreased survival. Well-known examples include the beautiful but cumbersome peacock's tail, the elaborate and seemingly arbitrary bowers constructed by male bowerbirds, and the magnificent songs of thrushes, which can attract predators as well as mates.

Just as more elaborate peacock tails presumably increased their owners' success in attracting peahens, strong allegiance to a particular host plant species boosted the mating success of hummingbird flower mites. Like other sexually selected characters, host affiliation involves a degree of arbitrariness and probably carries an element of risk as well. For a mite that has specialized on a single host species, even a brief flowering failure in the plant could mean the mite's extinction.

My co-workers and I suspect such extinctions must be rather common, on the scale of mere thousands of years. However, unless the flowering of all host species were to fail simultaneously from California to Chile and throughout the New World tropics—a most unlikely event—the future of hummingbird flower mites as a group seems assured. Their dynamic evolution all but guarantees that newly evolved species will eventually replace extinct ones, even in the same host plants. Some species even thrive harmlessly on the nectar of garden plants (including African aloes in California) along with the hummingbird visitors that delight the gardener. Despite the risks that they face daily, stowaway mites are well suited to life on the run. □

A long-tailed hermit hummingbird, bearing mites on its bill, samples the nectar of a scarlet passionflower. The mites will remain on the bird until it arrives at the "right" flower. By sharing an affinity for particular host plants, mites of the same species may expedite mate finding and improve their reproductive success.

Questioning Survival

by Norman A. Chance

Imagine, if you can, a human settlement in which the majority of those who die before the age of nineteen do so by their own hand, a place where violence is so pervasive that the odds of dying a natural or accidental death are only about one in four. Imagine, in a society once noted for its indulgent devotion to its young, that in one year one-third of the children between five and fourteen were taken from their parents by the Children's Aid Society for reasons of physical and sexual abuse, severe neglect, or abandonment. These are but a few of the statistics cited by Anastasia Shkilnyk in her penetrating and sensitive analysis of the fate of Grassy Narrows, a Canadian Indian community that has been devastated by change. In *A Poison Stronger Than Love: The Destruction of an Ojibwa Community,* we learn that in this small village in northwest Ontario, beatings, murder, rape, incest, senseless vandalism, and other forms of social pathology have become the collective norm. It is a world turned upside down.

Why, the reader may ask, would the community of Grassy Narrows, once highly supportive of kin and spiritually attached to the land, self-destruct in such a manner? What disasters could be so all-encompassing as to reduce a competent, self-reliant people to such a condition? A poignant though less than satisfactory answer is found in the response of a resident villager: "I can't explain it to you, because I can't explain it to myself. The only thing I know is that alcohol is a stronger power than the love of children. It's a poison, and we are a broken people."

The author describes in graphic detail the prolonged and frequent bouts of spree drinking, the most visible element of widespread alcohol abuse throughout the village. As an urban and regional development specialist, she knows such eruptions are but manifestations of a much deeper malaise. Yet even her experience working in the slums of Santiago, Chile, and in war-torn Ismailia, Egypt, had not prepared her for what she describes as the "numbness of the human spirit" that typifies the residents of Grassy Narrows. And so she set out to find the underlying causes.

Insights were not long in coming. Shkilnyk soon learned that in the summer of 1963, the nearby Indian Affairs office had begun relocating the residents of Grassy Narrows from their old "reserve" on the English-Wabigoon River to a new site on a logging road. In the opinion of the government, the relocation would make it much easier to provide the residents with a school, medical care, improved housing, electricity, and other benefits of a modernized Canadian way of life.

A POISON STRONGER THAN LOVE: THE DESTRUCTION OF AN OJIBWA COMMUNITY, by Anastasia M. Shkilnyk. *Yale University Press, $30.00 (hardcover), $9.95 (paper); 275 pp., illus.*

However, relocation also separated the people from their ancestral lands. It disrupted their social organization—the clan-based extended family. It reduced their participation in the seasonal economy of the region, trapping for furs in the winter and guiding sport fishermen in the summer. And it weakened their almost symbiotic relationship with the animals and land—a hallmark of their way of life. Such an economic and cultural disjunction carries a penalty well known among

North American Indian groups suffering similar travails of poverty, loss of identity, and decreasing ability to shape their own future.

Originally, kinship was the major factor in how Ojibwa society had organized its labor, determined access to its resources, and defined rights and obligations involved in their distribution and consumption. The Ojibwa channeled their economic efforts through these kin-based relations, and any part-time involvement in a cash economy supplemented rather than replaced their own means of livelihood.

Following relocation, the kin-based way of life on the winter trapline all but disappeared. School-age children were required to attend the newly constructed reserve school. A government-built housing development, modeled after densely populated white suburban communities, provided new homes for a people used to more isolated living arrangements. Moose hunting, a common subsistence activity in the spaciousness of winter encampments, became all but impossible in the confines of a year-round village settlement. Gardening, another mainstay on the old reserve, was largely abandoned because of the poor quality of soil at the new location. Most former hunters and trappers became subordinate producers in enterprises such as commercial fishing. In times of unemployment, welfare payments provided by a government trying to integrate the Indian population into the Canadian mainstream further encouraged this new dependency.

Unfortunately, this vicious cycle of forced migration, economic dependency, loss of cultural identity, and breakdown in social networks is not uncommon in Indian

Own America's First Silver Dollar

Original 200 year old coins that were legal tender of our 13 colonies

Minted from 1772-1821, these silver dollars were the most popular coins of our 13 colonies.

June, 1985, MONTPELIER, VERMONT — International Coins & Currency, Inc. a national distributor of numismatic coins, is offering for sale a limited number of original 200 year old coins — among the first large silver dollars minted in the Americas. These magnificent silver coins once circulated in our original 13 colonies and the early USA. Because of their high silver content and popularity, Thomas Jefferson recommended that they become official legal tender of the United States of America.

Minted from 1772-1821, these silver dollars were the most popular coins of our 13 colonies and were used as legal tender in the USA up until 1857. As collectors and investors turn to American coin classics, these scarce silver dollars are becoming increasingly sought-after and desirable.

Struck at the Americas' oldest mint in Mexico City and denominated 8 Reales, these silver dollars were the forerunners of the first U.S. silver dollar minted in 1794 — and served as the most favored trade coin in the world. Yet huge silver melts and the fact that relatively few were saved from destruction make these coins "sleeping" classics. Each silver dollar is a big 39.5 mm in diameter, contains 27.07 grams of .903 pure silver, and each comes with a Certificate of Authenticity attesting to its fine quality and genuine status. This guarantee never runs out. Because the supply was originally discovered in the Far East, genuine "Chinese merchant markings" are often visible and serve to authenticate the coins.

Because of the age and historical significance of these coins, you might expect to pay up to several hundred dollars for one. But while supplies last, they are available on a first-come, first-served basis for $75 each — and you can save up to $75 by buying more than one. International Coins & Currency, Inc. is offering for sale a limited number of these coins to collectors and investors at:

1 coin $75; 2 coins $150;
3 coins $215 (save $10);
5 coins $345 (save $30);
and 10 coins $675 (save $75).

There is a strict limit of 10 coins per customer. Your 100% satisfaction is guaranteed — you may return your order for a prompt no-questions-asked refund within 15 days (less postage and insurance of course).

To order your coins by credit card, call toll free at 1-800-451-4463, 24 hours a day, 7 days a week (including Sundays).

If you prefer, send check or money order in full amount to: International Coins & Currency, Inc. Dept. 793, 11 East State, P.O. Box 218, Montpelier, Vermont 05602. Add $3.75 for 1 coin or $5.00 for more than 1 coin to cover postage and insurance. Special presentation cases for individual coins are also available at $2.50 each. Mr. Douglas Schneible, ICC's Numismatic Director is Life Member No. 1305 in the American Numismatic Association. All coins are available for prompt delivery.

In Grassy Narrows, two-thirds of the adults are heavy drinkers. Hiro Miyamatsu

communities. Yet the long and well-documented history of similar processes among other native North Americans suggests that such events, socially and psychologically devastating as they may be, do not adequately explain the extreme self-destruction at Grassy Narrows. In Shkilnyk's mind, a key factor was still missing.

A 1967–68 report by Norvald Fimreite, a Norwegian biologist at the University of Western Ontario, suggested that another crucial environmental factor had played a role at Grassy Narrows. Fimreite had studied the impact of industrial mercury on fish and birds in the area. His conclusion: the fish downstream from a nearby pulp and paper mill and chloralkali plant contained unacceptably high concentrations of methyl mercury. Further research demonstrated that fish taken downstream from all the chloralkali plants in Ontario contained body burdens of mercury that were more than forty times the allowable federal standard of 0.5 ppm (parts per million). As the magnitude of this environmental disaster became known, commercial fishing was banned in the area, tourist camps closed, and affected residents were warned not to eat the contaminated fish.

In response to a broadside of criticism, the pulp and paper industry claimed it had—as Shkilnyk succinctly phrases the argument—a "license to pollute" from the Ontario government. Since it had respected existing environmental regulations, the company maintained it could not be held exclusively liable for the disaster. Such proposals laid the basis for the industry's overall view that mercury poisoning was a societal responsibility and that any claims for damages would have to be settled by the courts.

For the people of Grassy Narrows, methyl mercury carried a bundle of messages. It meant the total loss of employment in the now-banned commercial fishing industry and a large reduction in guiding and tourism. It meant a severe decline in their subsistence food supply. It meant a new poison, in addition to alcohol, was entering their bodies—a fact continually highlighted by lurid newspaper accounts, detailed medical investigations, and written warnings by governmental health authorities that some members of the village had abnormally high (above 100 ppm) levels of mercury in their systems. And finally, as they found themselves being used as pawns by the major players, government and industry, in what Shkilnyk refers to as the "politics of mercury," it served as a vivid reminder of their seeming powerlessness to influence the course of their own lives. As the residents described it, mercury was simply "the last nail in the coffin."

Today, 71 percent of Grassy Narrows residents are under twenty-four years of age. None have the skills that enabled their fathers to live in the bush. Unable to find employment in the wage economy, most young men and women are entirely dependent on government grants. Their sense of hopelessness, and that of their elders, is clearly reflected in the carefully selected montage of fine photographs taken for the volume by Hiro Miyamatsu.

Another, quite different, factor exacerbates this sense of despair. For the people of Grassy Narrows, as for many native North Americans, land is not just a part of nature; it is also endowed with spirits that transcend nature. Land is, in essence, a gift to be held "in trust" for future generations. If that trust is broken, if the land is damaged, assistance is unlikely to be forthcoming. After all, poisoned land, like poisoned people, becomes angry. This is in contrast to our Western economic system, in which property ownership is considered an inalienable right and land is bought and sold like any other commodity. Our North American marketplace has little interest in sharing, spirits, or communal stewardship. Instead, our values stress that problems can be solved through technology, that progress is intimately connected with the need for constant growth, that restrictions placed on competition should be minimal, and that the individual's initiative to excel—even at the expense of others—is to be admired and emulated.

The residents of Grassy Narrows have had to withstand a mounting series of attacks on their sustenance, their culture, and finally their bodies—an assault seemingly without end or solution. They are unable to shape their lives in a manner consistent with their beliefs and find little constructive help from outside their community. Frustration and anger have taken over. Whether this anger is directed toward others or, as is more frequently the case, turned inward in keeping with traditional cultural patterning, it is not likely to dissipate as long as the conditions promoting it remain unchecked.

Is there a lesson for the rest of us? Anastasia Shkilnyk responds in the affirmative, suggesting that many of the pressures crippling the people of Grassy Narrows are similar to those impinging on us. What happened at Grassy Narrows, she concludes, "can serve as a warning that our own survival depends on restoring a sense of mutual responsibility for one another and ultimately for the fate of the earth. Love has to become a stronger power than the poisons of self-interest and powerlessness or else we will all perish."

While teaching at McGill University in the 1960s, Norman Chance directed the McGill-Cree Project, a long-term study of Indians in central Quebec. Now a professor of anthropology at the University of Connecticut, he is currently engaged in research on Alaska's North Slope.

Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Cold Spirits

In the U.S.S.R., there is a minicuisine of flavored vodkas that began as home-grown folk art

by Raymond Sokolov

Russia's favorite cocktail, according to my favorite Russian cookbook author, Anne Volokh, is the Polar Star. "Take ½ glass vodka," she explains in *The Art of Russian Cuisine,* "add another ½ glass of vodka, and stir thoroughly." This passion for pure, clear spirits may seem witless and pathetic, but it is actually the basis for a fascinating minicuisine of flavored vodkas that has survived all the disruptions of the past eighty years and still stands as a testimony to the innate sensitivity of Russian palates.

Today, cooks in the Soviet Union would find it impossible to prepare many of the 4,000 dishes described in Elena Molokhovets's *A Gift to Young Housewives,* a classic Russian cookbook written in the 1870s for middle- and upper-class women. No new editions of this book by the Russian Mrs. Beeton have come out in Russia since 1917, but secondhand copies of *A Gift to Young Housewives* cost the moon now in Moscow. And, says Mrs. Volokh, "readers pore over it as if it were a historical novel, marveling at the quality of a life long gone."

A selective annotated edition of the Molokhovets book is now being prepared by Joyce Toomre at Harvard University. She kindly let me look at a chapter of the manuscript, which is a painstaking, scholarly effort to make this crucial document of late imperial Russian bourgeois life available to American readers. But the recipes are so old-fashioned and reflect such a different way of life that most cooks will not find it easy to translate them to practical effect in a modern American kitchen.

This is exactly what Anne Volokh has done with some of the Molokhovets recipes. She herself had not cooked many of them until she left the U.S.S.R. and gained access to suitable raw materials in American markets. Volokh was the food writer for the Sunday edition of the Soviet newspaper *Izvestia* before she and her family emigrated to Los Angeles. Her cookbook was published in 1983, and it is an extraordinary achievement for several reasons. First, it is hugely informed and professional, with an encyclopedic array of recipes written with the clarity and authority that come from years of practice at a popular newspaper. Volokh has also taken the trouble to tell an American audience how Russians feel about their food and how they consume it. In other words, her book is strong on context and sociology. It is also literary, rich in gastronomic quotations from classic Russian authors.

These toothsome passages are not just there as gorgeous window dressing. Taken together, they form a mosaic of a lost world of Russian abundance and hospitality. Heading the chapter on *zakuski,* or hors d'oeuvres, for example, is this epigraph from Gogol's *Dead Souls:*

> "And now we shall send boredom packing," the host said. . . . "Why aren't they serving the snacks?" The door opened. Emilian and Antoshka appeared with the napkins, laid the table, and set down a tray with six decanters of various flavored vodkas. A necklet of plates displaying every kind of tempting savory soon surrounded the tray and decanters. The servants moved about smartly, bringing in covered casseroles which gave off a sizzling sound of melted butter. . . . After the snacks came the dinner.

Anyone interested in exploring what those snacks were or what was served in the dinner that followed could do no better than to read Volokh and cook her recipes. But lately I have been reading her for a more specific reason. During the past few months, I have been preoccupied with flavored vodkas for reasons that will become clear in a moment. And the Volokh volume is the most complete authority on the subject, even better than Molokhovets's book, which ignores vodka concoctions of the sort now popular in the Soviet Union.

The Molokhovets recipes for vodka involve cooking—vodka is heated with, say, fruit and sugar, and ends up verging toward such Western delicacies as brandied pears or blackberry cordial. The prepared vodkas I am concerned with are also traditional, but they are cold infusions of highly aromatic substances. They are always served ice cold, and their purpose is to isolate flavor, in its very essence, without the distraction of sweetness. The closest examples from other cultures that come to mind are the white alcohols distilled in France from a mash of pears or raspberries (or, less commonly, from plums, wild strawberries, and holly). But these luxurious "brandies" begin as fruit. The Russian flavored vodkas start as neutral spirits and are doctored with powerful flavoring elements that no one would normally eat separately.

In the U.S.S.R. today, according to Volokh, what was evidently a home-grown method of spicing up vodka has been industrialized. She mentions four brand names—Starka, Ierofeich, Petrovskaia and Okhotnichia—labels applied to vodkas infused with "anywhere from 3 to 4 flavors—sage, heather honey, angelica root, ginger root, anise, juniper berries, Crimean apple and pear leaves, mint, young shoots of mountain ash, nutmeg and nutmeg blooms, vanilla, cinnamon, cardamom, cloves and others." The commercial producers of these drinks mix an

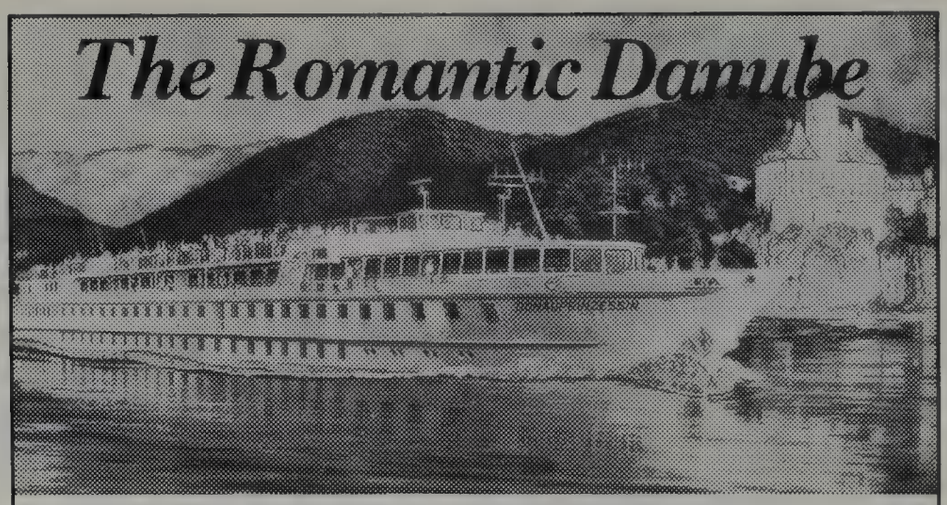
Matter of Taste

end them from a copious spice shelf, but ussians who flavor their own vodkas at ome tend to work with one flavoring ele- ent at a time.

The most famous example of this is the odka infused with an herb called buffalo rass, or *zubrovka.* Also well known are odkas in which caraway seed, citrus peel, ack pepper, or chilies have been macer- ed at room temperature for a week. Pep- er vodka, or *pertsovka,* a chili-inflamed, mber-colored eye-opener, is available ommercially in this country at large li- uor stores. But it is so easy to make that it hardly worth spending money on an im- orted product or wrestling with qualms bout trading with the enemy to acquire And if you try one of the following reci- es, you will probably be tempted to ex- eriment on variations that suit your own stes.

This must have been the spirit in which his whole genre of drinks was originally onceived—people puttering about at ome, dropping one thing or another into a ottle of hooch to make it taste better. nd yet it would be misleading to pass off avored vodkas as a sort of low-class folk rt. Volokh talks about the major-domo of he English Club in Moscow in the nine- enth century, an epicure called Shably- in, who supervised the creation of vodkas avored with birch and black currant uds.

The cult of these flavored vodkas has re- ently spread to the United States. My uru in this area is an American Slavicist, Martin Horwitz, whose lemon vodka was he inspiration for my own improvisations. s you drink one of these flavored vodkas, ou are swept away by the intensity of aste. And if you reflect about the phe- omenon, it will eventually occur to you



Enjoy seven magical days of cruising aboard the luxurious Danube Princess on Europe's most beautiful river.

Better than Jogging, Swimming, or Cycling...

NordicTrack

Jarless Total Body

Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Cross-country skiing is often cited by physiologists as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles so higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the pleasant X-C skiing motion and provides the same cardiovascular endurance-building benefits–right in the convenience of your home, year 'round. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

More Complete Than Running

NordicTrack gives you a more complete work out– conditions both upper body and lower body muscles at the same time. Fluid, jarless motion does not cause joint or back problems.

More Effective Than Exercise Bikes

NordicTrack's stand-up skiing motion more uniformly exercises the large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass.

Even Better Than Swimming

NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. When swimming, the body is supported by the water, thus preventing these muscles from being effectively exercised. The stand up exercising position on the NordicTrack much more effectively exercises these muscles.

A Proven, High Quality Durable Product

NordicTrack is in its 7th year of production. NordicTrack is quiet, motorless and has separately adjustable arm and leg resistances. We manufacture and sell direct. Two year warrantee, 30 day trial period with return privilege.

Folds and stands on end to require only 15" x 17" storage space.

Discovery Tour to the Nile

February 9 to March 1, 1986

Discover the world of ancient and modern Egypt on an American Museum 600 mile Nile Cruise. Explore with three lecturers the rich natural and archeological sites of an area which has fascinated visitors for centuries...A carefully planned itinerary (with a special two-day program in London visiting the British Museum with its curator) provides a relaxing and thorough three-week Discovery Tour. All of the major Nile archeological sites as well as the important wildlife regions are discussed and visited with your balanced team of eminent lecturers. Share with Museum staff and friends an unforgettable cruise. For further information including itinerary, map, prices, conditions, etc., write or call American Museum Discovery Tours.

that it is odd that extreme cold is an indispensable part of the experience.

The idea of serving flavored spirits cold is well established and, of course, is not exclusively a Russian notion. The Swedish version of flavored vodka, caraway-infused aquavit, is customarily served right from the freezer and is sometimes presented with the bottle frozen in a block of ice. This is not done merely for show. I have repeatedly experimented with side-by-side tastings of ice-cold and room-temperature samples of the same flavored alcohol and found the cold drinks exhilaratingly focused in aroma and the tepid ones insipid.

Normally, cold reduces the intensity of flavors, while heat increases them. Think of the smells that spread through a house from an active kitchen, and then think of the same food, pale and inert, as it comes from the refrigerator the next day. And yet, the most intense distillations of flavor I know come from very cold foods: flavored vodkas and ice cream (especially water ices). In both cases, the flavors are the main point of the food. And when the temperature of vodka or sherbet rises, its taste interest falls. (Clearly, the texture of an ice changes abruptly at 32 degrees Fahrenheit, but it is no great feat to ignore texture in a tasting, and the flavor appea of ices and ice creams does definitely dro as temperature rises.) This happens be cause of the complex physical chemistr that affects our perception of volatil odors.

To begin with, most of what we think o as tasting is actually smelling. This is espe cially true of sensations affected by tem perature: heat increases the volatility o flavors. And that is why cold, which slow down their escape into our olfactory recep tors, reduces flavor intensity, in a genera way. But not all aromatic substances reac to temperature uniformly. Cold stifle some flavors more easily than others.

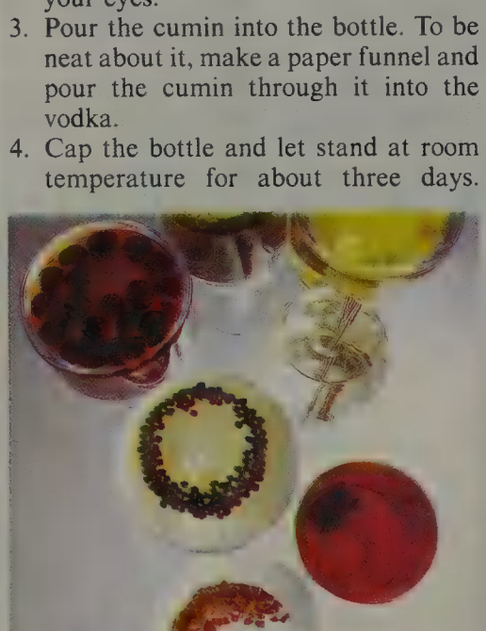
"There's a whole different profile of fla vor at different temperatures," says tast consultant Gail Vance Civille, "differen colors, different notes. Orange juice has different flavor if it's warm or cold."

The Russians who first started flavorin vodkas did not know anything about th olfactory "pictures" that are Civille stock in trade. But they did see that ce tain substances would withstand th damping force of cold and stand out dra matically when the usual elements of voc ka's basic taste were suppressed. They in stinctively chose flavorings of hig intensity, many of them chosen for th

Tex-Mex Vodka

1 quart 80-proof vodka
3 dried red chilies
1 tablespoon ground cumin

1. Open the bottle of vodka.
2. Crumble the chilies and carefully drop the debris, including the seeds, down the neck of the bottle. Now wash your hands. The chilies will have left a residue on your fingers that could burn your eyes.
3. Pour the cumin into the bottle. To be neat about it, make a paper funnel and pour the cumin through it into the vodka.
4. Cap the bottle and let stand at room temperature for about three days. Taste each day to test how well th maceration is proceeding. When tastes just hot enough, strain th vodka, then pour it back into the bo tle.
5. Tighten the cap and put the refille bottle in the freezer. As soon as the li uid is very cold and has turned so vi cous that it pours like a light syrup, it ready to drink. Always serve very col



Richard Jeffery

You can, of course, make a wide rang of drinks in this way. For instance, take vegetable peeler and cut the zest (the co ored surface layer) off one lemon or on orange. Macerate with 2 teaspoons sugar in a quart of vodka for 4 days. Or tr using a dozen berries from a mountain as or 2 tablespoons of caraway seeds, left develop flavor for a week.

Rose Brandy

(From *The Art of Russian Cuisine*, by Anne Volokh, Macmillan, 1983)

25–30 roses, fully opened
3 bottles (750 milliliters each) 8 proof vodka
4 cups sugar

1. Remove the rose petals and place in large jar. Add the vodka, seal the j tightly, and set in a warm place (76 80 degrees Fahrenheit) for 2 to

ne reason as spices or as flavorings in mitive medicines. These flavorings d to be rich in essential oils or acid, ich stand up to cold more fiercely than weaker elements present in vodka.

To test this idea, I cast about for a sub- nce rich in essential oils that had not, so as I knew, been used to flavor vodka. min came immediately to mind. min plants are umbellifers closely re- ed to caraway and fennel. I put cumin o vodka with three dried chilies and ded up with a powerfully interesting nk, the olfactory essence of the Mexi- n border (see recipe).

Lest you think that only taiga-bound ssians and drudges like me fiddle ound with cold-intensified flavor, here is example of peerless elegance in this e. I have it on good authority that the thschilds freeze Château d'Yquem, the eatest dessert wine on the planet, before ey drink it at their own Château Lafite. st before serving, they let the wine de- st to a pourable slush. The cold sup- esses the sweetness and leaves only the ulous bouquet.

weeks. When the liquid turns golden, strain it carefully through 4 layers of cheesecloth.

In a 4-quart enameled pot, make a syrup with the sugar and ½ cup water. Add the rose brandy and bring to a boil. Remove from heat and away from any open fire. Skim the surface. Cool. Pour into bottles, seal tightly, and keep in a cool place for 4 to 6 months.

Yield: Approximately 3 quarts

Sorbet of Apricots à la Moscovite

Based on a recipe from *The Book of Ices,* by A.B. Marshall, London, 1855. Reprinted in *Victorian Ices and Ice Cream,* edited by Barbara Ketcham Wheaton, Scribner's)

⅓ cup plus 1 teaspoon apricot jam
2 tablespoons maraschino liqueur
1 tablespoon rum or brandy
Diced preserved fruit or fresh fruit

Stir the jam together with 2½ cups cold water and push through a fine sieve or purée in a blender.

Stir in the maraschino liqueur and rum or brandy.

Freeze until firm in an ice cream freezer.

Serve with diced fruit.

Yield: About 1 quart

SHOW YOUR KIDS HOW A FOREST IS LOGGED.

Dress 'em up in old clothes and sturdy shoes, and we'll take you all "into the woods" on a comprehensive tour of one of our logging sites.

You'll discover how lumberjacks and foresters work with computer programmers and lab scientists to sustain our forests *and* their yields forever. Your kids will go "Wow!"

We offer you tours like this because we'd like you to understand that our mills and plants and logging sites serve your interests as well as ours.

And because we're proud of them.

For a list of tour locations, write Sharon Ramsey, Boise Cascade Corporation, One Jefferson Square, Boise, Idaho 83728.

Paper/Office Products/Packaging/Building Products/Forests

Summer Brights

by Thomas D. Nicholson

The bright planets are divided between the morning and evening skies this month, but with a little bias toward the morning. Venus and Jupiter are morning stars, Saturn and Mercury evening stars, and Mars goes from evening to morning. During the evenings, when the summertime constellations are up, Saturn is low in the south at sundown and sets in the southwest about an hour after midnight. It's in Libra, about midway between Virgo's Spica and Scorpius's Antares, and about as bright as these two stars. When its retrograde motion ends late in the month, Saturn begins edging toward Antares. Jupiter, on the other hand, is much brighter and more easily seen after it climbs high enough in the west, about three hours past sunset. Since it is still a morning star, Jupiter remains in the sky for the rest of the night. While Venus is well up in the east at dawn, Jupiter hovers in the west until twilight wipes it out. Mercury gives us a fair shot in the evening sky but not its best. If the sunset sky is exceptionally clear, you may see the planet in the west-southwest in late twilight from about March 10 to 20.

The following events are given in eastern standard time unless stated otherwise.

July 1: Tonight's moon might look full, but it isn't. It's half a day shy of being full, and there are two ways you can tell: it rises about half an hour *before* the sun sets, and one portion of it is a bit uneven. Binoculars show it easily. Tomorrow night (*after* full moon) the opposite part of the moon will look uneven.

July 2: Full moon is at 7:08 A.M., and the moon rises about thirty-five minutes *after* sunset.

July 3–4: The gibbous moon is in Capricornus, approaching Jupiter, the bright object to its left. It passes below the planet early in the evening of the 4th.

July 5: Earth is at aphelion (farthest from the sun), but our weather probably won't give you a clue. The slight change of the earth's distance from the sun over the course of the year has little effect on the weather.

July 6–7: The gibbous moon (rising after 10:00) is a good guide to the Square of Pegasus and the star Fomalhaut tonight.

The summer Sky Map identifies constellations and stars for the months of July, August, and September from latitude 40° N at the evening hours given below. To use the map, hold it vertically in front of you with south (S) at the bottom, and match the lower half of the map with the stars you see facing south. As you face in other directions, rotate the map to bring the corresponding compass direction to the bottom of the map.

The stars move west continuously during the night. By morning (before dawn), stars on the western half of the map will have set, those on the eastern half will have moved into the west, and new stars (those of the fall evenings) will have risen in the east. The map represents the sky at about 2:00 A.M. on July 1; 1:00 A.M. on July 15; midnight on July 31; 11:00 P.M. on August 15; 10:00 P.M. on August 31; 9:00 P.M. on September 15 and 8:00 P.M. on September 30. Add one hour for daylight time. The map can be used for an hour or more before and after the times given.

Helmut Wimmer

Look after midnight, when they have risen high enough. The two westerly (right-hand) stars of the Square are above the moon and Fomalhaut is below.

July 9: Last-quarter moon is at 7:39 P.M. It rises close to midnight in Pisces.

July 10–11: The waning crescent moon, now in Aries, rises shortly after midnight. It reaches apogee (farthest from earth) at 3:00 A.M. on the 11th.

July 13: Mercury is at its greatest distance to the sun's left (greatest easterly elongation) today, placing it in its best position as an evening star when the sun sets. But best isn't good enough this time. The planet may be seen low in the west during twilight for a week or so before and after the 13th, but it won't be easy.

July 13–14: The morning crescent moon joins Venus in the eastern sky. Both rise before dawn and are well up before twilight obscures them. The moon slowly approaches Venus on Saturday morning and passes north of the planet on Sunday morning.

July 15: Still near its prime as a morning star, Venus majestically drifts past Aldebaran, the bright ruddy star of Taurus. But even Aldebaran pales in Venus's brilliant glow. A glimpse at the rising crescent moon, below and to their left, may be the last before new moon.

July 17: New moon, at 6:56 P.M., is near Gemini's border with Cancer. Mars is finally in conjunction with the sun.

July 19: The young crescent moon shows up tonight in Leo, in front of the Lion's mouth. Regulus, the bright star at Leo's heart, to the moon's left, is easier to see. The conjunction of the moon with Mercury won't help much in finding the elusive planet, far south of the crescent.

July 20–23: Not much happening these days, except the crescent moon is fattening and slowly drifting east through Leo and Virgo. But it does wonders for a clear summer's evening to see that crescent up there from twilight into the dark of night. Try following the moon nightly as it drifts away from Leo and Regulus, in the west, toward Virgo's bright star Spica, high in the south.

July 23–24: The moon shifts from Spica's right to its left these nights. The cres-

Don't Buy a BIG TILLER...

For a Small Job!

Buy a Mantis!

Big tillers weigh almost 300 lbs. Mantis weighs just 20 lbs. (women and older gardeners love it)!

Simply turning a 300 lb. tiller in a backyard garden is a challenge. Mantis starts with a flick of the wrist . . . turns on a dime . . . and weeds between narrow rows and along fence lines.

The Mantis takes the work out of growing flowers and vegetables . . . so you can have more time to enjoy the results!

Most big tillers were designed to just till, Mantis was designed *from the beginning* for a variety of useful attachments. Tiller. Weeder. Furrower. Edger. Lawn Aerator. Lawn De-Thatcher. Hedge Trimmer.

Best of all, Mantis costs a *fraction* of what you'll pay for a big tiller.

3-Week In-Your-Garden Trial!

Mantis has a *Lifetime Warranty* on the tines (if they ever break, we'll replace them). A *Lifetime Replacement* agreement on the engine. And a *3-Week In-Your-Garden Trial* (if you don't like it, we'll take it back and give you a full refund).

I use my Mantis to weed a large flower garden that used to take four days to complete — with the Mantis it takes only one hour. Now I have time to enjoy my flowers.

cent becomes the first-quarter moon at 6:39 P.M. on the 24th.

July 25: The moon is at perigee in Libra, near Saturn. Early on Friday morning, the moon passes Saturn, but after the two have already set.

July 26: Saturn ends its retrograde (westerly) drift through Libra, signaling that its sojourn as an evening star is soon to end. Mercury, on the other hand, signals the end of its evening performance by beginning its retrograde motion today.

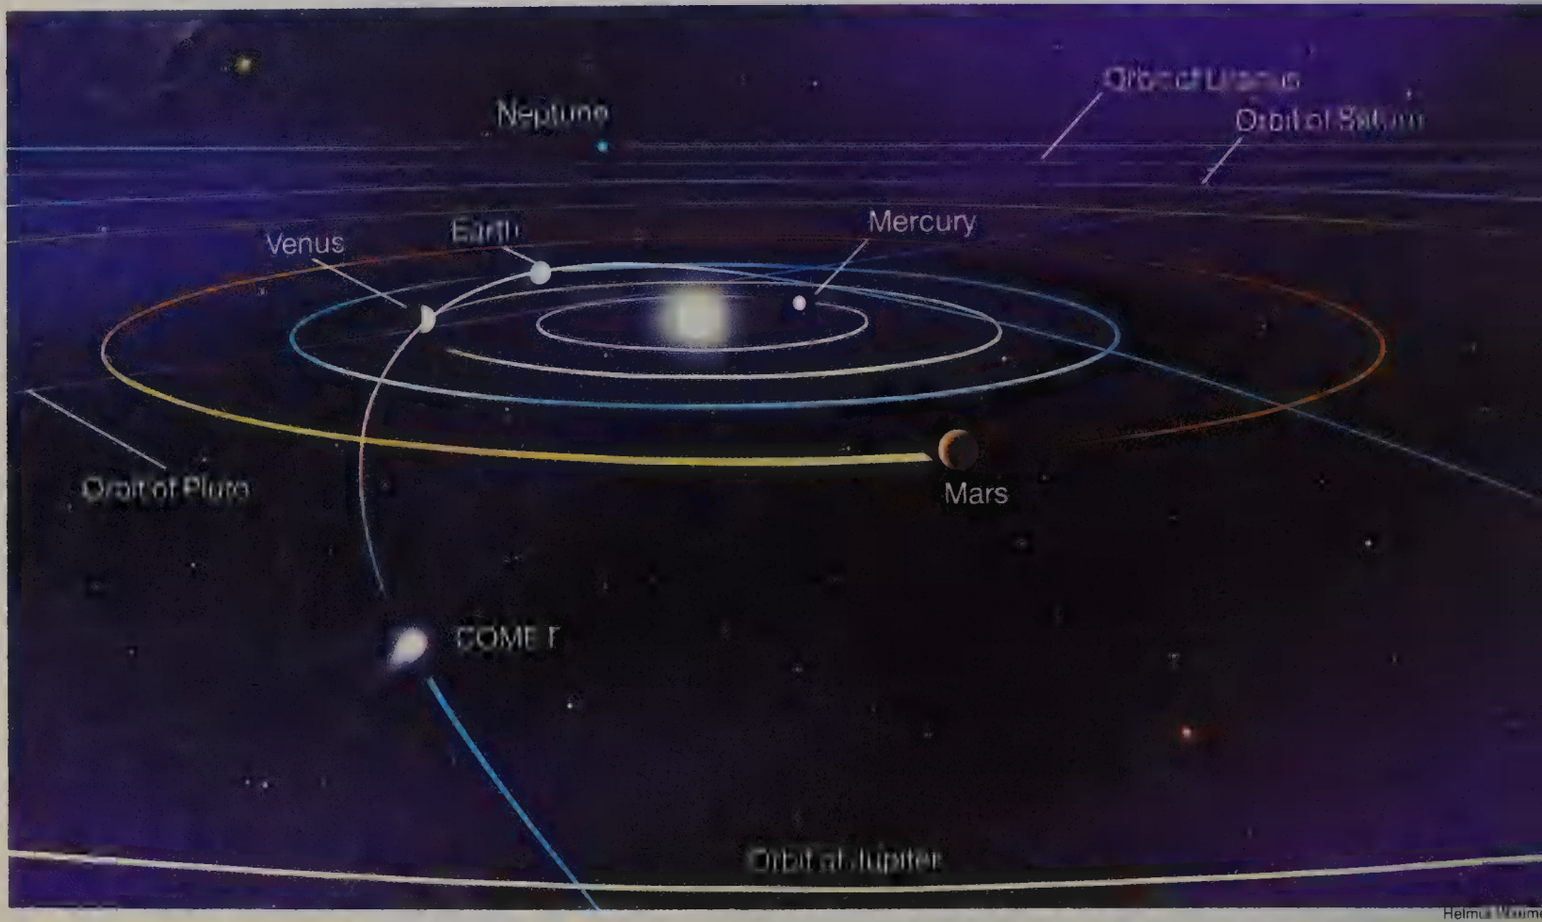
July 27: The reddish star to the moon's right is Antares, in Scorpius.

July 28: The southern Eta Aquarid meteor shower—broad, sparse, relatively slow, and dim—is at maximum today. Not too great a display, but with the moon setting about 1:00 A.M., dark skies should help see the shower.

July 29: The gibbous moon is in Sagittarius, but it is not yet bright enough to hide the stars of the Teapot, below and to its right.

July 31: The second full moon of the month is at 4:41 P.M., in Capricornus. Note that the earlier one was in Sagittarius, about one-twelfth way around the sky to the west. The bright object above the moon is the planet Jupiter.

Halley's Comeback



Halley's comet is now in Taurus, where the "heliacal rising" occurs each year in July. The term designates the rising of a star when it is first seen again after being invisible due to its nearness to the sun. The stars of Taurus rise in the east just before dawn. The sun, which passed through Taurus about a month earlier, rises about two hours after this star group during July.

Taurus, with its bright red star Aldebaran, is well known as a winter constellation. In winter, the sun is halfway around the sky away from the group; it rises in the early evening and is part of the sky scene all night long. Between now and then, Taurus, with Aldebaran as its "point star," rises earlier each day, remaining visible for longer in the morning sky before the brightness of twilight wipes it out.

If it didn't enter the sky so close to dawn, Zeta Tauri (the third-magnitude star at the tip of Taurus' left horn) would be an excellent marker to help searchers find Halley's comet with large telescopes. But star and comet rise too late and the comet is too faint to make trying worthwhile this month.

Late in July, the comet moves into Gemini, very near the summer solstice, the point in the sky where the sun is on June 21. It ends its retrograde motion in September and swings west again through Taurus, remaining within the boundaries of the constellation for several more months. The stars of Taurus move into better position for viewing in the months ahead, and so does Halley's comet. Beginning in August, amateur astronomers may have a good chance of spotting the comet.

The comet is still doggedly edging its way closer to the sun in July, cutting the distance by more than thirty million miles. Under the acceleration of gravity, its speed continues to build to more than 45,000 miles per hour. In this month's illustration, the comet is very nearly on the opposite side of the sun from Earth. But it is moving to the right around the sun, while Earth is moving to the left. The motions of the earth and the comet take them closer to one another, and that will continue until the close pass of November 27. This month, the distance between Earth and comet decreases by more than 55 million miles. At midmonth the comet is 389 million miles from the earth, 307 million miles from the sun.

Note that I referred to the easterly motion of Halley's comet during its retrograde loop. The retrograde motion of all the planets is westerly, of course. The diagram shows why. The comet's motion is opposite to the orbital motion of the planets. So the comet's direct motion is westerly, and when it retrogrades it appears to turn in an easterly direction.

EMBERS'
EW YORK
EEKEND

NEW YORK, NATURALLY!

(Designed exclusively for Members of the American Museum of Natural History)

Whether your first love is art or archaeology, elegance or evolution, Tiffany or Tyrannosaurus rex, the stars of the heavens or the stars of Broadway, you'll find it in our Members' New York Weekend. For three exciting days and two wonderful nights, a great city and a great Museum will be all yours.

- **Two nights in one of New York's finest hotels:** Stay at The Waldorf Astoria, The Parker Meridien, or The Plaza. Minutes away from New York's famed theater, shopping, and eating districts and only a short ride away from the Museum itself.
- **Two complimentary meals:** Enjoy a full breakfast at your hotel and a leisurely lunch in the Museum's charming greenhouse-style restaurant.
- **The Official Guide and a Highlights Tour:** As soon as you make your reservations, we will send you the Museum's Official Guide to introduce you to our fabulous treasures. And when you arrive at the Museum, take a Highlights Tour, which provides fascinating insights into the Museum's most popular halls. Or savor the Museum at your own pace. Journey through halls filled with gems, dinosaurs, myriad life forms, and peoples from all over the world. The Star of India sapphire, wolves hunting in the night, ancient totems of the Northwest Coast, and Mayan sculptures are just a few of the Museum's varied wonders. At the end of your visit, relax in our private Members' Lounge or take advantage of your Members' discounts at Museum gift shops.
- **Special Exhibitions:** The Museum presents an exciting schedule of special exhibitions throughout the year. Through July: *Maya: Treasures of An Ancient Civilization* and *John James Audubon: Science into Art.*
- **Free Planetarium and Naturemax Tickets:** Journey through the heavens in the Planetarium's famed sky theater and enjoy the film experience of a lifetime at Naturemax, with its movie screen sixty feet wide and over four stories high.
- **Personalized Service:** The Members' Service Desk will help customize your weekend to suit your needs and tastes. They'll be glad to arrange theater or concert tickets, reservations at New York's top restaurants, a carriage ride through Central Park, or tours of the town.
- **Discount air fares:** Special rates are available on American Airlines, the official airline of the Members' New York Weekend.

Tour Program Price: $92.50 per person, per night. Tax included. Based on two nights double occupancy. Rates also available for families and individuals.

LEARN FRENCH ON YOUR OWN!

Not just a phrase-guide approach, but a *real* language course, offering 15 to 40 hours of recorded material. From the very first minute you'll be learning French the same way you learned English – by listening and repeating. It's easy, and takes only 25 minutes a day. Your cassette player becomes your "teaching machine." You learn where and when you want to, and at your own pace.

You can count on the high quality of this course, since it was developed by the U.S. Foreign Service Institute to train State Department personnel. Available in two parts; order either, or save 10% by ordering both.

- ☐ **Basic French Part A:** 12 cassettes (15 hr.) and 194-p. text, $125.
- ☐ **Basic French Part B:** 18 cassettes (25 hr.) and 290-p. text, $149.

(Conn. residents add sales tax.)

Phone orders call toll-free: 1-800-243-1234

To order by mail, clip this ad and send with your name and address, and a check or money order – or charge to your credit card (VISA, MasterCard, AmEx, Diners) by enclosing card number, expiration date, and your signature.

Unconditionally guaranteed. Order today! We offer courses in 41 other languages; send for free catalog.

The Amagansett Whale

The American Museum of Natural History's collection of whale skeletons is stored in an echoing, cavernous space. This cement and brick building previously housed the huge generators that powered the Museum's complex of buildings. Today, instead of humming generators, the room is filled with enormous plastic-shrouded skeletons of whales. The ceiling is still a tangle of metal tracks and winches, once used for moving the powerhouse machines but now used for shifting the skeletons of the leviathans.

Although the Museum's collection of the larger whales contains only about a dozen specimens, it is one of the biggest in the world. (The entire collection also contains several dozen smaller whales and more than 400 other cetaceans.) Whales are the biggest animals that have ever lived—bigger even than the dinosaurs o mammoths—and they are a formidable challenge even for major museums.

The Museum's first important whale came from Amagansett, Long Island. I was obtained by two young men—Roy Chapman Andrews and James L. Clark—both of whom would later become well known as explorers.

Andrews got into whale collecting by accident. In 1906, when he began working at the Museum as a part-time floor washer, the institution possessed only a few miscellaneous whale bones. Nevertheless, Museum director Hermon C. Bumpus decided to create and exhibit a full-size replica of a great blue whale. He hired a whale expert to build the creature and pulled Andrews away from his janitorial duties to be the man's assistant. He also

Planetarium Events

Starting June 27, the Hayden Planetarium will feature two new sky shows. The first, *Hayden: The Golden Years,* celebrates the Planetarium's fiftieth anniversary. It looks back on five decades of astronomical history, examining how our perceptions of the universe have changed; then looks ahead to the next fifty years to what we may yet discover. The second show, *Halley's Comet: Once in a Lifetime,* tells where and when to look for Halley's comet. It will also explore the nature of comets and discuss how scientists will use Halley's return as an opportunity to study a comet in more detail than ever before. For more information and show times call (212) 873-8828.

Native American Month

July will be *Native American Month* at

signed Andrews's roommate and friend, mmy Clark, to the project.

The replica was a disaster. The model-aker tried to construct it by covering a ood-and-iron framework with paper. But e paper sagged and buckled between the os, giving the animal an emaciated ap-earance. After weeks of watching the an try to prop up the pathetic-looking hale, Bumpus finally lost his patience. ccording to Andrews's book, *Ends of the arth,* the director called Andrews and lark into his office and said, "This whale getting on my nerves. It is beyond all en-urance. What shall we do?" The two oung men immediately recommended at Bumpus fire the whale expert and re them to finish the job, using papier âché instead of paper. Bumpus agreed.

In 1907, while Andrews and Clark were

e People Center. Each weekend, dance nd theater performances, lectures, dem-nstrations of crafts and examples of Na-ve American music will be featured om 1:00 to 4:30 P.M. The programs are ee and visitors may drop in at any time.

rt of the Cameroon

On July 15, a new exhibition, *Art of the Cameroon,* will open in Gallery 1. Most of he one hundred and fifty pieces on dis-lay date from the turn of the century and re from the traditional royal courts of Cameroon's savanna region. Among hem are sculptures, baskets, figures, and ewelry. Many of the items have been bor-owed from private and public collections n America and Europe, as well as from he private collections of the *fons* (kings) f the Cameroons. Highlights of the show nclude a feather cape and a number of ood sculptures intricately decorated ith colorful beads. The exhibition, which being circulated by the Smithsonian In-titution Traveling Exhibition Service, is upported by a grant from the Mobil Cor-oration. It will remain open until Octo-er 15.

Fitness Master LT-35

TOTAL SYSTEM FOR CARDIOVASCULAR FITNESS.

Simulates cross-country skiing, regarded by fitness authorities as the top cardiovascular exercise. Rated higher than jogging, swimming, biking or rowing.

- Fluid motion — no jarring impact on bones and joints. Avoids running related injuries.
- Excellent for weight control and body tone.
- Stable, unit rests flat on floor. Lightweight for portability. Weighs only 35 lbs.
- Easily stored. Folds to 5 inch height. Slips under bed or stands upright in closet.
- 30 day home trial. 2 year warranty.
- Can be used by men and women regardless of size or weight. Height and resistance adjustable.

building the whale (it would hang in the Museum for half a century before being replaced with a bigger model), a record-size Atlantic right whale was killed off Long Island. Bumpus decided he wanted to preserve the complete skeleton with its baleen (the long, fringed, platelike sheets of horny, elastic material that some whales use to filter plankton from the water while feeding) for the Museum. He dispatched Andrews and Clark to Amagansett, where the whale had been brought ashore.

When they arrived at the town, they sought out Josh Edwards, the 76-year-old retired sea captain who had harpooned the whale from a shore-launched boat, and Andrews negotiated to buy the whale's remains. In those days, baleen, an essential component of women's corsets, was extremely valuable. Therefore the sum of $3,200—very high in turn-of-the-century dollars—was finally settled upon as a just price for the baleen; Edwards threw in the rest of the skeleton "for free."

Andrews and Clark found the whale lying near the low-tide mark, partly awash in the surf. Since fishermen had already stripped off its blubber and flukes, the whale was a grotesque-looking pile of meat, and it took several minutes to distinguish the head from the tail. The fifty-four-foot skeleton was still buried in about fifty tons of flesh. Waves washing over the carcass had left it glazed with ice.

To help them carve the meat off the skeleton, Andrews and Clark hired a half-dozen local fishermen. The men set to work on the carcass with long knives, slicing off giant sections of meat so heavy they had to be dragged from the body with a horse, grappling hooks, and rope.

On the the third day, a storm beat down from the east. "We saw it coming," Andrews wrote,

and anchored our whale as best we could, working waist deep in the icy water. For three days the shore was a smother of white surf. Anxiously we waited . . . . The fourth day was dead calm but very cold; twelve degrees above zero at noon. When we got to the beach, a smooth expanse of sand, innocent of whale, met our eyes. The bones had disappeared.

After a moment of horror, Andrews and Clark realized that their anchor ropes were still in place but buried in the smooth sand. They began digging into the beach, and soon the carcass came to light. "As soon as we dug out a shovelful of sand to get at a bone," Andrews wrote,

the depression filled with water. We had to grope blindly with small knives, our arms i the freezing water up to the elbows, to di articulate each vertebra. None of the fish ermen would work at any price. It seeme hopeless and I don't mind saying that never have suffered more in any experienc of my life than I did then. But the directo told us to get every bone and we simpl couldn't give up.

At last some of the fishermen decided t help when they saw us two kids strugglin hopelessly in that icy water . . . . At the en of a week a huge pile of bones lay well u along the beach.

Andrews and Clark made an inventor of their find, checking each bone against drawing of a right whale skeleton owne by the Smithsonian Institution. Much t their disappointment, several cruci bones were missing—including the tw slender vestigial pelvic bones (evolutio ary remnants of the hip bones of th whales' land-dwelling ancestors). "Searc as we could," Andrews wrote, "Jimm and I could not find those wretche bones." Suddenly, it occurred to Andrew that the bones could have come off wit the blubber and might be found at the tr works (a brick furnace where blubber rendered). They arrived there just after load of blubber had been dumped into a

y Chapman Andrews and the Amagansett whale

n vat, and Andrews fished around in the
bbling fat with a net. Soon, he had
gged not only the two pelvic bones but
o several smaller bones known as the
horal rudiments. Rarely preserved in
seum specimens, these were important
evolutionary studies.
The Amagansett whale was a female,
d after she was killed the fishermen no-
ed a calf swimming aimlessly along the
ore. A short time later the calf was har-
pooned near Wainscott, Long Island, and Andrews purchased its skeleton as well. It was later traded to the British Museum (Natural History) for the skeleton of a dodo bird, now on display in the Biology of Birds Hall.

Both whale skeletons—partly disarticulated—were hauled to the railroad station by horse-drawn cart and shipped to New York via the Long Island Rail Road. Once at the Museum, the bones were further cleaned, boiled in maceration vats, and degreased with benzene. Finally they were neatly numbered and installed in the Museum's storerooms.

Because Andrews had secured the whales for the Museum, Bumpus rewarded him with a scientific plum: Andrews was allowed to be the first to study the rare specimen. Later, he led several expeditions to Japan, China, and other areas in the Far East to collect more specimens from whaling operations. While in China, Andrews conceived the Museum's Central Asiatic Expedition, one of the most important in the history of natural science (see "A Nest of Dinosaurs," *Natural History,* March 1985).

The bones of the Amagansett whale rested in the Museum's storeroom for many years before they were dusted off and mounted for exhibition. Finally, in 1934, the grand skeleton was hung in the Museum's Hall of Ocean Life. It remained on display until the 1960s, when the Museum's ninety-four-foot model of the great blue whale was set up. Today the bones are stored in the old powerhouse, together with the rest of the whale collection, an important resource for scientists all over the world.

Liftoff

Bee-eaters "come [across] as alert and vivacious birds," wrote Scottish ornithologist Hilary Fry, and that may be a mild way to describe birds that routinely blast out of their nests like rockets. Most of the twenty-four species are extremely active, foraging for honeybees and social wasps during most of the daylight hours. Carmine bee-eaters, according to Fry, often don't even bother to perch when they're foraging. Like swallows, they stay aloft, "sailing around leisurely and . . . with a few quick beats, effortlessly twisting after an insect."

The rainbow bee-eater, shown here, is native to Australia. It's a gregarious bird that nests colonially in sandy plains, earthworks, gravel heaps, and roadside and river banks. The nest tunnels are often dug into flat ground and occasionally into sand cliffs. Both sexes do the digging but have a habit of making false starts, repeatedly abandoning one effort to begin another. "These false starts seem to be a pointless waste of effort and a study of the problem is needed," Fry wrote in his book *The Bee-Eaters,* published last year.

When finished, the tunnel is usually more than three feet long, and when it is built in flat ground it generally slopes down to a depth of about sixteen inches. The egg chamber at the end of the tunnel is about sixteen inches long, eight wide, and three high. A female rainbow bee-eater usually lays four or five eggs. She, her mate, and often, male helpers take turns incubating them.

In some parts of Australia, people consider the arrival of big flocks of rainbow bee-eaters the official beginning of spring. Bert Wells and his wife, Babs, celebrated the new season recently by setting up camera equipment and a high-speed flash outside a nest tunnel near their home in Western Australia and taking, as he says, "one of our best shots ever."

Additional Reading

Floral Scents (p. 28)

Coevolution of Animals and Plants, edited by Laurence E. Gilbert and Peter H. Raven (Austin: University of Texas Press, 1980, paperback), includes a pertinent review of the biochemical coevolution of plants and herbivores. It discusses ant–plant interactions, as well as the scent of orchid flowers and its effect on the bees that visit the plants. Ann H. Zwinger and Beatrice E. Willard's *Land Above the Trees* (New York: Harper and Row, 1972) is a gracefully written introduction to the natural history of alpine Colorado. *Flower Pollination in the Phlox Family*, by Karen A. Grant and Verne Grant (New York: Columbia University Press, 1965), surveys the various pollinators of phlox flowers and analyzes the natural history and adaptations of the flowers. Peter G. Kevan and Herbert G. Baker's "Insects as Flower Visitors and Pollinators" (*Annual Review of Entomology,* vol. 28, pp. 407–53) explores the different kinds of insects that visit flowers, focusing on pollinators.

Maori (p. 36)

Michael King's *Maori: A Photographic and Social History* (Auckland: Heinemann Publishers, 1983), a comprehensive history of the Maori people, has a wide range of pictures that illustrate almost every aspect of Maori life since the advent of photography. The greater part of the book records how Maori life changed in response to the arrival of Europeans in New Zealand and how Maori culture managed to remain intact. *Natural History*'s last article on the first New Zealanders, "Maori Power" (September 1984, pp. 54–59), with photographs by Athol McCredie, announced the national tour of "Te Maori," an exhibition that marked the first time the Maori had allowed their traditional artworks to travel abroad. *Te Maori: Maori Art from New Zealand Collections* was the accompanying catalog (New York: Harry N. Abrams, 1984). In *The Maori: Heirs of Tane* (London: Orbis Publishing, 1982), David Lewis tells the story of the Maoris' arrival in New Zealand some time after A.D. 750, and traces their history as hunters and fishers and, later, in the twelfth and thirteenth centuries, as farmers. Lewis investigates this new agricultural system, which led to a way of life structured around extended family clans and governed by gods, and follows Maori history to the nineteenth century, when the Europeans arrived in New Zealand.

El Chichón (p. 46)

The December 1984 *Journal of Volcanology and Geothermal Research*, edited by J.F. Luhr and J.C. Varekamp (published by the Elsevier Scientific Publishing Co., 52 Vanderbilt Avenue, New York, New York 10017, 212-916-1250), devoted to the eruptions of El Chichón. It contains eight articles by specialists in volcanology, geochemistry, and atmospheric science on such subjects as the relationship between explosive volcanism and the earth's climate; the stratigraphy of pyroclastic deposits; the character of the eruptions, ash fall deposits, and gas phase; and the nature of the stratospheric cloud. *Geofísica Internacional,* a Mexican scientific journal, also published a special issue (vol. 23) on El Chichón, with fourteen articles (in English) on the effects of the eruptions. Write to the Universidad Nacional Autónoma de México, Instituto de Geofísica, Circuito Exterior, Mexico 20, D.F., Mexico, for more information. Although the eruptions of El Chichón were relatively small, they injected a volcanic cloud into the stratosphere denser than any since the eruption of Krakatau in 1883. Michael R. Rampino and Stephen Self consider the climatic implications of the eruptions in "The Atmospheric Effects of El Chichón" (*Scientific American,* January 1984, pp. 47–57). In November 1982, *National Geographic* ran two articles on El Chichón: Bonfil Weintraub's "The Disaster of El Chichón" (pp. 653–71), which considers the economic as well as the atmospheric impact on people, and Robert I. Tilling's "Volcanic Cloud May Alter Earth's Weather," (pp. 672–75). Both are illustrated superbly.

Hummingbirds (p. 56)

Alexander F. Skutch has studied hummingbirds in their native homes in tropical America for more than forty years, and his book *The Life of the Hummingbird* (New York: Vineyard Books, 1973) is one of the better introductions to these birds. The book is nicely illustrated by Arthur B. Singer. Skutch's *Naturalist on a Tropical Farm* (Berkeley: University of California Press, 1980) describes his life on a farm in southern Cost

ca. Although nearly all the surrounding odland has been destroyed by agricul-e, he has managed to preserve a large ct of tropical rain forest. Paul A. nsgard's *The Hummingbirds of North nerica* (Washington: Smithsonian Insti-ion Press, 1983) is one of the more thor-gh works on these birds. It summarizes ir comparative biology (including evo-ion, anatomy, ecology, behavior, and productive biology) and their natural tories. *Hummingbirds: Their Life and havior* (New York: Crown Publishers, 85) includes 235 full-color photographs Robert A. Tyrrell, including never-be-e photographed sequences of nesting, lting, preening, and territorial aggres-n, as well as a portfolio of hum-ngbirds feeding from wildflowers. The t, by Esther Quesada Tyrrell, admira-presents up-to-date information on the al statistics of each of the North Ameri-n species, but it is the photographs that ke this book stand out. Larry L. Wolf d F. Reed Hainsworth compiled and edited articles from a symposium on the ecology and behavior of nectar-feeding birds; you can find these in the *American Zoologist*, vol. 18, pp. 618–819. One of the best books on mites to start off with is Asher E. Treat's *Mites of Moths and Butterflies* (Ithaca: Comstock, 1975). Treat, a New England naturalist, is known in the mite field for his discovery that mites of the species *Myrmonyssus phalaenodectes* infest the "ears" of the army worm moth, destroying their tympanic membranes. Interestingly, the mites confine their damage to only one ear. The book's first chapter is particularly recommended; it is one of the better introductions to mites around. Robert K. Colwell's "Competition and Coexistence in a Simple Tropical Community" (*American Naturalist*, vol. 107, pp. 737–60) is a readable description of interactions between mites and hummingbirds. Colwell will contribute "Community Biology and Sexual Selection: Lessons from Hummingbird Flower Mites," a more technical version of his article in this issue, to a book due out at the end of this year; titled *Ecological Communities*, it is being edited by Ted Case and Jared M. Diamond. David S. Dobkin conducted an interesting experiment on how mites react to the microclimate inside flowers. After inserting tiny wires, called thermocouples, that accurately indicate temperature, inside the flowers, Dobkin then manipulated the temperatures and recorded the mites' reactions. He explains his research in "Heterogeneity of Tropical Floral Microclimate and the Response of Hummingbird Flower Mites" (*Ecology*, vol. 66, pp. 536–43). Among the many books on pollination, we recommend the following: *The Sex Life of Flowers*, by Bastiaan Meeuse and Sean Morris (New York: Facts on File, 1984); *Pollination Biology*, edited by Leslie Real (New York: Academic Press, 1983); and *Handbook of Pollination Ecology*, by C. Eugene Jones and R. John Little (New York: Van Nostrand Reinhold, 1983).

Nearly seven years ago, **Candace G len** (page 28) realized that the sky pil one of central Colorado's most acc sible and abundant tundra plants, w more than "just another pretty face" the region's crowd of alpine wildflowe Why, she wondered, did some of t plant's flowers smell sweet and oth skunky? Galen's work on the plant led a Ph.D. from the University of Texas Austin. Now a postdoctoral fellow at t University of Toronto, Galen is condu ing field and laboratory studies of the namics of bumblebee–plant relati ships in eastern Ontario. In Septemb she will begin duties as an assistant p fessor at Bowling Green University Ohio. Galen's diversions include mou taineering, rock climbing, fishing, wr ing poetry, playing clawhammer ban and juggling.

Michael King (page 36), a New Z land historian, has been writing abo the Maori for more than a decade. 1983, he published his most recent a controversial book, *Maori: A Pho graphic and Social History.* "The c troversy was not about the writing or t history," notes King, "but over whet non-Maori should still be writing Ma history in light of the current drive ward cultural self-determination. In

mosphere that now prevails, non-aori writers on Maori topics are aded toward obsolescence." King, no has a doctorate from the University Waikato in New Zealand, has worked rd at taking New Zealand history out the universities and back into the com-unity. He has won awards for earlier ojects in history and journalism, as ell as for his work in television docu-entaries.

HEAVY DUTY INFLATABLE BOATS

2 MAN $38
3 MAN $50
4 MAN $65

Before Midnight
For The Next 30 Days

As part of an advertising test, *Dunlap Boat Mfg.* will send any of above size boats to anyone who reads and responds to this test before the next 30 days. Each Boat Lot No. (Z-26 PVC) is constructed of tough high density fabric (resistant to abrasions, sunlight, salt & oil), electronically welded embossed seams, nylon safety line grommeted all around, heavy duty oar locks, 3 separate air chambers for extra safety (4 air chambers in 4-man), self-locking safety valves, bow lifting & towing handle and are recommended for marine, ocean and fresh water recreation, camping, fishing or a family fun boat. Each boat will be accompanied with a **LIFE-TIME** guarantee that it must perform 100% or it will be replaced free. Add $7 handling & crating for each boat requested. *Dunlap Boat Mfg.* pays all shipping. If your order is received within the next ten days you will receive FREE a combined hand/foot inflator/deflator bellows style pump for each boat requested. Should you wish to return your boat you may do so for a full refund. Any letter postmarked after 30 days will be returned. LIMIT three (3) boats per address, no exceptions. Send appropriate sum together with your name and address to: Boat Dept. #285B, *Dunlap Boat Mfg.*, 2940 W. Pico Blvd., Los Angeles, CA 90006. Or for fastest service from any part of the country call 1-800-824-9988 for Boat Dept. #285B (Calif. residents call collect 213-735-9363), before midnight seven days a week. Have credit card ready.

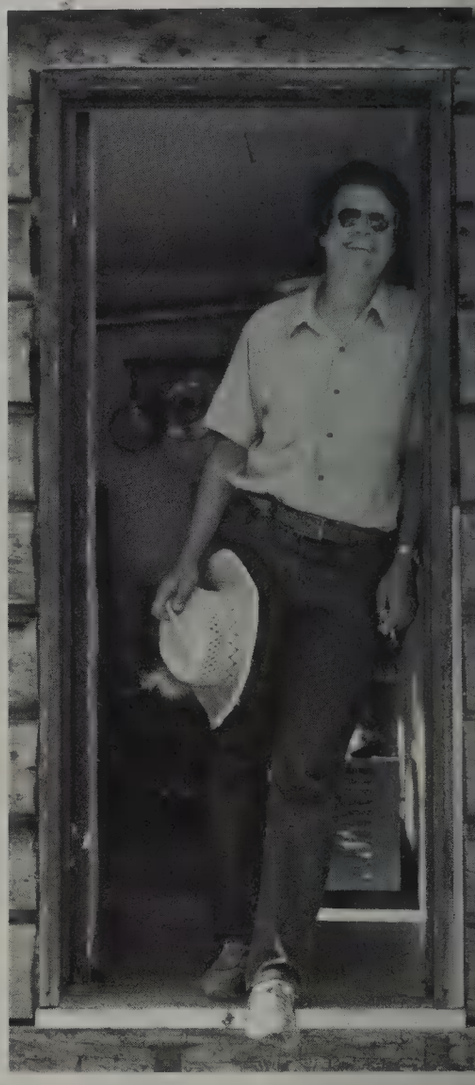
The last time *Natural History* readers heard from volcanologist **Haraldur Sigurdsson** (page 46) was in March 1982, when his article "In the Volcano" appeared. At the same time, a newly active volcano in Mexico hit the headlines—El Chichón. In this issue, Sigurdsson reports on the scientific expeditions that followed once things had quieted down. The photo shows him (center) with coauthor **David Gardella** (right) and another member of the research team, Steven Carey. They are breakfasting at their ash-covered headquarters, five miles from El Chichón's crater. Born in Iceland, Sigurdsson is a professor at the University of Rhode Island's Graduate School of Oceanography, where he combines teaching with research on the mineralogy and geochemistry of volcanic rocks. He has investigated numerous volcanoes, on land and in the ocean basins. David Gardella, who participated in the expedition to El Chichón, works in Massachusetts as a writer and sales manager. He first met Sigurdsson when they were graduate students at the University of Durham in England.



Most people live all their lives without giving a thought to hummingbirds' nostrils, much less to the fauna therein. They haven't met **Robert K. Colwell** (page 56), who presents the "other world" of hummingbird flower mites with you-are-there freshness in this issue. Now a professor of zoology at the University of California at Berkeley, Colwell has been a visiting professor at universities as far afield as Texas, Sweden, and Chile and has carried out field studies in Latin America and the Caribbean. His present interest in the evolution and ecology of biological communities, particularly the relationship of arthropods, such as mites, to plants and vertebrates, grew out of his work in Costa Rica, a home of his namesake, the mite *Rhinoseius colwelli*. Curiosity and love of nature run in the family. In Kenya, at the age of four, Colwell's daughter, Emily, "collected" an aloe flower for him; inside they found the first Kenyan sunbird flower mite known to science.

Bert Wells (page 82) became a naturalist-photographer in 1970, mainly to escape a boring job in the city. He quickly gained numerous international awards, including the Award of Excellence from the International Federation of Photographic Art in Switzerland, and a listing in *Who's Who in Photography,* published by the Photographic Society of America. His wife, Babs, is a field ornithologist, and Wells relies on her to point him in the right direction when they're out in the bush of Western Australia. Their most recent work was *The Wild Pilbara,* a photographic study of Western Australia's rugged northwest region. Wells's shot of a rainbow bee-eater blasting out of a nest tunnel, in this month's "The Natural Moment," was taken with a high-speed flash (1/10,000 of a second) and a 35-millimeter lens.

The last time she saw England.

The newlyweds were off to live in America. She had put off ying good-bye until the very last moment.

As always, he had something for her: an antique cameo rooch. "It was your mother's," he said. "I know she'd want you have it." Then she tried to put her feelings into words.

But how do you begin to tell the person who single-andedly raised you how much you love him?

Call England. Ten minutes can average just 76¢ a minute.*

Saying good-bye is never easy—but saying hello is, with AT&T. ten-minute phone call to England can average as little as 76¢ a minute.

Just dial the call yourself any night from 6 pm until 7 am.

If you don't have International Dialing in your area, you'll still get ne same low rate as long as special operator assistance is not required.

AT&T International Long Distance Service.

yers and Slappers

I don't know anything about Mormon cones" ("A Matter of Taste," June 985), but I do know about American In- an fry bread. Mr. Sokolov hit the nail on e head when he related it to the French *eignet*. The one true original Indian fry ead began among the Indians of the reat Lakes, who were educated in cook- g and theology by the French missionar- s. Wheat was unknown to the Algonkian nd Siouan tribes of the Lakes area. So as frying. Combined, as in the *beignet*, ey were irresistible, and Indian women ught on quickly. Fry bread spread east- ard to the Atlantic and southward down e Mississippi drainage. It is even possi- e to classify Indian women as fryers and appers. Slappers adopted the Mexican ethod of slapping unraised corn dough etween the palms, thus producing torti- as. Fryers need little explanation, beyond dding that they use raised dough.

The Navajo slap out tortillas and cook em on flat stones, preferably soapstone abs. Since World War II, when Navajo rvicemen met up with servicemen from ther tribes, women have made fry read—not "fried bread," Mr. Sokolov— r festive occasions.

exual Stereotypes

"Superheroes in the Doll Corner," by ivian Gussin Paley (March 1985), pre- nts what I think is a false picture of "sex- al self-stereotyping." Ms. Paley presents e behavior of kindergarten boys and irls as if it arose naturally with no influ- nce from the environment; as if the chil- ren created the sex roles themselves, ather than picking them up from the ex- mples set for them from birth.

Her article tacitly presumes this is na- ure taking its course. I propose an alter- ate explanation: at this age children be- in to identify themselves with the stereo- ypes they have been presented with since irth. Sexual stereotyping is so insidious in his society that we don't even notice it ost of the time, but a close examination f television commercials and children's rogramming (adult programming, too, r that matter), storybooks, even science ooks shows males as active, females as se- ate; men as saviors, women as victims. here is no other paradigm available to he developing child.

RENNY CHRISTOPHER
Gilroy, California

Vivian Gussin Paley replies:

Renny Christopher blames the biases of adult society. Others find explanations for the differences between boys and girls in biological fact or psychosexual theory. Without rejecting any of these approaches, I offer still another piece of the truth: group consciousness.

Boys and Girls follows a class of kindergarten children as they respond to the newest, most exciting phenomenon in their lives, the emerging separate-sex peer group, which they define primarily in terms of its fantasy play. My purpose is to describe this remarkably different play and to suggest that, in the classroom, boy–girl differences are not as important as the adult's attitude toward those differences.

Rhesus Recovery

Dr. Siddiqi and I wish to go on record as having several objections to the editorial treatment accorded our article on rhesus monkeys (February 1985). The title, "The Rhesus Monkey's Fall from Grace," is inappropriate because the rhesus monkey is a sacred species and therefore cannot "fall from grace." People of all religions may modify their behavior under economic pressure; but for many Hindus the rhesus remains a sacred species. The title selected by *Natural History*'s editors confuses religious values with economic pressures and agricultural expansion. The subtitle, "There is little place left in modern India for a sacred species," gives the wrong impression. We have maintained for years that India *does* have a place for a sacred species and we have written and spoken often of the extensive areas where the rhesus can thrive without excessive economic problems. In addition, we have proposed ways to reduce agricultural conflicts.

Two of the captions are misleading: We have not documented extensive decline of the rhesus in Nepal and have, in fact, noted the stability of the rhesus there; and we would never refer to the rhesus as being "ubiquitous" in the cities of India, nor would we compare them with "pigeons in New York."

In our opinion, the selection of photographs misrepresents our research and the article's intent. Our studies concentrated on agricultural environments, not temples or cities, as shown on the cover and in five out of six photographs in the article. We do not want to perpetuate the myth that most rhesus in India are associated with

WILD AMERICA IS OUR CAMPUS

Career programs leading to AA, B.S. and M.S. degrees

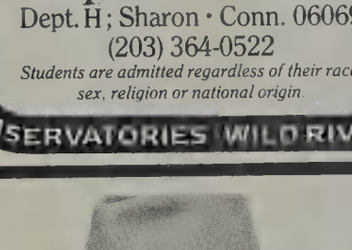
You can't fully learn about the environment by sitting in a classroom. Our expeditions are small groups of inquiring college, high school, graduate students and faculty who travel across America as a learning community. As we camp out September-May or summers—hiking, canoeing and skiing—we visit people and places to encounter deep ecological problems, society and self. Our 4-week to 4-year cross-cultural studies —Newfoundland to California—lead to naturalist, outdoor and educational livelihoods.

The Expedition Education Advantage. ❑ incorporates all previous undergraduate coursework, ❑ offers accredited career internships, independent study, life experience credit and transferable coursework, ❑ awards financial aid and career startup funding.

Send for complete information packet or inquire:

National Audubon Society Expedition Institute
Dept. H; Sharon · Conn. 06069
(203) 364-0522

Students are admitted regardless of their race, sex, religion or national origin.



SNOWY RIVER by AKUBRA®

The hat from the Australian Outback, pre-shaped in Akubra's Imperial Quality pure fur felt. 3¼" brim, color grey or fawn. Shown with hand braided leather band.

No. 1611 SNOWY RIVER, Ribbon Band **$60.00**
For 10 plait braided band add $13.50
State size 6¾ through 7⅞, and color

Check, Mastercard or Visa. Add $2.00 for shipping. Satisfaction Guaranteed. Send for our unique catalog. Visit our Seattle store at 1525 N.W. Ballard Way.

temples. Finally, the names of two of our respected colleagues in India—Dr. K.K. Tiwari and Dr. R.P. Mukherjee—were misspelled.

We would also like to add that although declining primate populations were of concern to the government of India, the key factor precipitating the export ban on primates was the demonstration by the International Primate Protection League that rhesus monkeys were being used in the United States for inhumane laboratory experiments. The failure to include this was our omission.

After twenty-six years of work in India, we are distressed by these misleading impressions and hope that this letter will clarify our position.

Jacobson's Organs

In "A Bite to Remember" (April 1985), Robert K. Colwell refers to the heat-sensing pits of *Bothrops asper* as Jacobson's organs. This is not so.

The Jacobson's organs are two pits located in the roof of the mouth. The tongue picks up external material particles and transfers them to the Jacobson's organ, which then transmits the resultant sensations to the brain. The Jacobson's organ should, therefore, be considered as an organ of taste; it has nothing to do with temperature perception.

It should also be noted that heat-sensitive pits are found in pit vipers, while the Jacobson's organs are found in all snakes and lizards.

JOHN O. HOLLISTER
San Antonio, Texas

Robert K. Colwell replies:

Mr. Hollister is correct. An early draft of the article pointed out that vipers use *both* the heat-sensing loreal "pits" *and* the chemosensory Jacobson's organs to detect prey, but the two were somehow confounded during the process of revision and I failed to catch the error.

In Defense of Coconuts

As a consultant to the Philippine coconut industry since 1962, mostly unpaid or underpaid, I have kept abreast on current developments in microbiology and nutrition regarding the coconut and its products. In this connection I have read, with considerable consternation, "The Perilous Seed," by Raymond Sokolov.

In most instances the intake of coconut meat, either fresh or desiccated, or of unmodified coconut oil as part of a normal diet containing adequate levels of the essential fatty acids has no evident disadvantage. Thus, it should not be compared to diets rich in cholesterol and coconut oils solidified by chemical hydrogenation. Finland, where the population consumes the fattiest diet in the world, principally of animal origin, exhibits the highest incidence of coronary heart disease and stroke. By contrast, the Philippines, Indonesia, and Thailand, where coconut is the major dietary fat, exhibit a significantly lower incidence of heart disease and stroke than many other countries.

CARL P. SCHAFFNER
Professor of Biochemistry-Microbiology
Rutgers University

More Clock of Evolution

In "A Clock of Evolution" (April 1985), Stephen Jay Gould describes studies of bird phylogeny based on DNA-DNA hybridization. Gould claims that through such work "the problem of phylogeny has been solved" and that he "does not fully understand why we are not proclaiming the message from the housetops." The explanation is simple: any such proclamation would be at best premature and at worst fallacious. Gould states that "the decoding of phylogeny requires no more than a method for recognizing homology and eliminating analogy." More is, in fact, required: primitive homologous similarities must be distinguished from recent ones. Doing this for distance data (like the bird DNA annealing values) is problematical. For example, the phylogenetic trees constructed from such data attempt to account for the observed "distances" between species; the greater the distance, supposedly, the more ancient the common ancestry. But the phylogenetic trees that best fit observed data sometimes require species to be separated by negative, rather than positive, distance values. This result is farcical (common ancestors don't really live in the future) but itself provides evidence that DNA annealing distances are not clocklike. Such anomalous results could be attributed to sampling or measurement error, but if the data are subject to such error, they are not a reliable guide to phylogeny, much less the panacea Gould envisions.

Phylogenetic analyses of actual DNA amino acid or nucleotide sequences are much better than brute force distance approaches like DNA hybridization and immunology. Unfortunately, obtaining actual sequences is a slow and costly procedure.

NORMAN I. PLATNICK
American Museum of Natural History

World Wildlife Fund announces an original work of art in hand-painted porcelain.

Hi There!

Newest work in the distinguished series of baby animal sculptures in porcelain from the World Wildlife Fund.

Art of fascination and charm at the attractive price of $45.

The World Wildlife Fund has undertaken the creation of a delightful collection of porcelain sculptures of baby animals.

Hi There! portraying a charming little panda, has just been completed for this collection. It is crafted in fine porcelain—entirely hand-painted—and is being issued at the modest price of $45, which itself is payable in convenient monthly installments of $15 each.

This new and original work of art has been designed *exclusively* for the World Wildlife Fund by Eva Dalberg, one of the world's most gifted portraitists of animals. Dalberg was chosen for this commission because of her very special ability to capture in art the charm and affectionate quality of baby animals.

Here, the little panda is portrayed in an amusing situation—eyeing a tiny caterpillar as it moves defiantly toward him along a bamboo branch, wondering how it ever had the colossal nerve to get *this* close!

This intriguing new sculpture will be crafted in fine porcelain and completely painted by hand. So every color and detail will be clear, crisp and exact. The caterpillar's slinky green body and upturned head. The panda's black-rimmed eyes, perky ears, chubby feet—and that curious expression of puzzlement on his face!

Hi There! will be crafted for the World Wildlife Fund, under the supervision of Franklin Porcelain. Each imported sculpture will be backmarked with the official "WWF" symbol.

You will enjoy displaying this charming little panda in your home and showing it to your friends. And you'll have the satisfaction of knowing it is created in a long-established tradition. For of all porcelain pieces collectors prize, figures of baby animals are among the most popular.

To reserve your sculpture, send the application at right to the World Wildlife Fund, c/o Franklin Porcelain, Franklin Center, PA 19091, by August 31, 1985.

Heaven's Alarm to the World

Halley calculated its return, but others read the comet of 1682 as a warning from on high

by William E. Phipps

Late in the summer of 1682, Edmund Halley of Oxford and Increase Mather of Boston observed and interpreted the movements of the same comet. Halley's cometary theory made him the most famous of English astronomers, while Mather's cometary prognostication helped him become the foremost American-born Puritan. The two views reveal a fundamental dichotomy, the difference between a naturalistic and a supernaturalistic explanation of physical events.

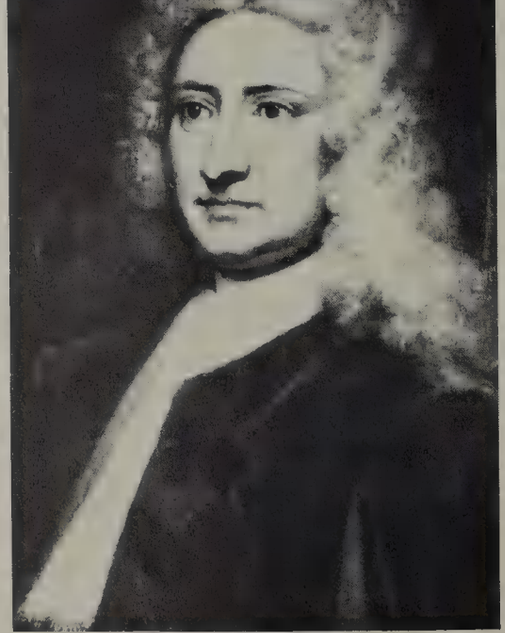
Although Mather defined a comet as "a company of small stars growing into one body" and acknowledged that a comet, like an eclipse, "happens according to the course of nature," he imbued both comet and eclipse with dire meaning, seeing them as "signs of divine anger." This almighty wrath was directed at mankind, specifically toward Mather's parishioners and others in the New England colonies. Had not Harvard University president Chauncy and two local governors died within a year of the 1677 solar eclipse?

From his North Church pulpit, Mather, prompted by the comet of 1680, preached a sermon entitled "Heaven's Alarm to the World." He delivered another address on comets on August 31, 1682, to the congregation he would serve for fifty-nine years. An expanded version of these discourses, which effectively provoked more dread, was published in 1683 with the Greek title *Kometographia*. It was the first book about comets issued in the Western Hemisphere. Mather's rigor on this and other themes—such as "damnable witches" inspired by Satan—secured his prominence in Massachusetts. Accordingly, he was chosen president of Harvard and retained that position for the remainder of the seventeenth century.

A graduate of Harvard, Mather had also studied in Europe. He brought home a traditional Old World explanation of celestial events. For millennia, he claimed, comets had virtually always been seen as "messengers of evil tidings." To defend this harbinger-of-doom theory, Mather cataloged portentous comet appearances "from the beginning of the world unto this present year." The calamities he listed include cultural conflicts and natural catastrophes that chanced to coincide with comet sightings: In 2292 B.C. (exactly 1,656 years after the world was created), a comet announced the Noachian deluge. In A.D. 66 a "blazing star was attended with a terrible persecution in which the apostles Paul and Peter were put to death." A comet augured ill about A.D. 620, when "Mohomet began to diffuse his pestiferous doctrine." The fiery 1066 comet presaged the death of King Harold II and William of Normandy's ascension to the English throne, while another in 1456 was followed by a destructive earthquake in Italy, a great plague, and Turkish military victories over Christians.

When Mather differed with one contemporary astrologer's interpretation of a 1652 comet, he was quick to scorn his rival and set the record straight. He referred to his opponent as "a blind but insolent buzzard" who "undertook to predict strange things from the appearance of this blazing star that never came to pass." The comet actually foretold, Mather disclosed, the "infection" of Quaker ideas in the world.

Greenwich Observatory



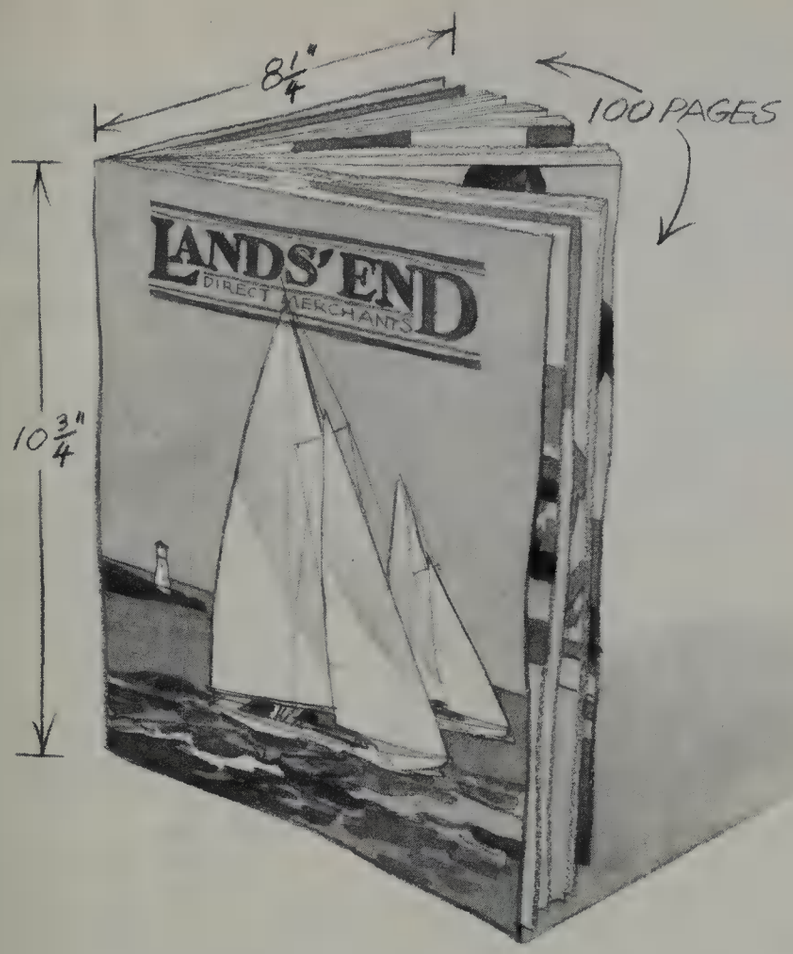
Edmund Halley, 1656–1742

After the 1682 comet, Mather assured his congregation that they could expect "a cold and tedious winter, much snow and consequently great floods; malignant and epidemical diseases."

For Puritans, comets truly signaled "mischiefs and miseries hastening to follow and fall down on the heads of senseless and secure sinners," and they termed this belief "special Providence." By giving comets theological weight and import, American Puritans strengthened the authority of an already powerful clergy. A comet's meaning could be validated only by certified spokesmen of the established Massachusetts religion, not by other astrologers, laymen, or scientists.

Halley was just twenty-five when he seized the only opportunity during his lifetime to observe the comet that now bears his name. He then painstakingly collected all the records made by other comet watchers and was dismayed that most records had been kept by astrologers eager to forecast doom to particular groups of people. Johann Kepler, however, had carefully described nearly identical movements of a 1607 comet, and after unearthing the record of a similar sighting in 1531, Halley wrote his friend Isaac Newton: "I am more and more confirmed that we have seen that comett now three times since ye year 1531." After calculating an elliptical orbit of about seventy-six years in his *Synoptics of Cometary Astronomy*, Halley asserted: "I may venture to foretel that it will return again in the year 1758." When his prediction was fulfilled, Halley was fittingly given the posthumous honor of being a cometary namesake.

Halley and Newton were mutually indebted. Halley recognized Newton's reticence as well as his genius and pressed him to communicate publicly the ideas that Newton had conveyed to him privately. Halley even financed the publication of Newton's *Principia* in 1686. The preface of that landmark book of astrophysics cites "the most acute and universally learned Mr. Edmund Halley"; he was the only person to whom Newton expressed appreciation. By applying the uni-



The Store We Mind

Our store is 10¾ inches tall, 8¼ inches wide, and 100 pages deep.** It has no crowded parking lots, clogged elevators, or hidden rest rooms.

It displays over 450 pieces of merchandise. And by the time you count colors and sizes and shapes and variations, you are up to 7,700 items you can shop from—assembled under one "roof" from the four corners of the earth, wherever quality calls.

Most of these items are shown on or with models so much like you they could live in your neighborhood. Every item is unconditionally guaranteed by the world's shortest guarantee. In two words: GUARANTEED. PERIOD.

We mind our store 24 hours a day, 7 days a week. You can buy from us in the comfort of your own home. But first, remember, we're only a phone call away—wherever you live. The toll-free telephone number: 800-356-4444. Or send in the coupon at right for a free look at our "store".

Oh, yes—we accept AX, MC, or VISA. And we deliver by United Parcel Service or U.S. Mail. You name it.

versal gravitation theory contained in *Principia* and Kepler's laws pertaining to the path and speed of bodies in the solar system, Halley deduced the periodicity of comets. The comet's return in 1758 not only proved Halley correct but also physically confirmed the laws of Kepler and Newton.

Thus Halley's empiricism heralded a modern world of rational inquiry, while Mather's rigidity harkened back to a medieval realm of divine threat and retribution. The cleric "read" Halley's comet of 1456 just as Pope Callistus had in the fifteenth century. The pontiff had appointed a time of prayer and fasting to redirect the divine judgment, so that it would conveniently smite the Turkish Muslims.

Although the popular appeal of astrology is undeniable even today—a Gallup survey discloses that 29 percent of Americans still believe in it—Mather's view was becoming obsolete among men of learning even in his own time. When he claimed competence in divining meanings of celestial phenomena, Mather set himself apart not only from Kepler, Newton, and Halley, who were also religiously oriented men, but also from the mainstream of his professed religion. Disdain for astrology was one important way in which biblical religions diverged from other ancient religions. The dominant religions of Western culture regard astral fatalism as incompatible with moral freedom. Although Mather thought of himself as a staunch Calvinist, a century earlier, John Calvin himself had rejected fatalism and advised theologians not to seek answers to astronomical questions in religious texts.

As surely as his predecessors believed the earth to be the core of the universe, Mather espoused a largely human-centered view of natural phenomena. Comets and eclipses were created, he believed, primarily to impact earthlings. Celestial sights were not wondrous visions granted to God's people on earth but threats, signs of paternal anger, and tools for enforcing authority. Halley saw comets as manifestations of gaseous elements, indifferent to stargazers, astronomers and astrologers alike, but subject to laws discernible by humans. His outlook stands in bold relief to astrology, which perennially finds human prejudices reflected in the heavens and human futures fated by their configuration. Halley viewed the A.D. 66, 1066 and 1456 comet apparitions, to which Mather referred, as unportentous earlier orbits of the same comet.

William E. Phipps is professor of religion and philosophy at Davis and Elkins College, Elkins, West Virginia.

Do a friend a favor. Do yourself a favor...

The card below could win you a free Hawaiian vacation

in Natural History's "View the World" Sweepstakes!

Grand Prize: A week long vacation for 2 in beautiful Hawaii* ...fly on a wide-bodied American Airlines jet to Hawaii and relax in your own condominium suite. We provide an Avis rent-a-car with unlimited free mileage so you can see all the sights. No contests or quizzes. All we ask is that you help us (if possible) to win new friends for *Natural History*.

1st Prize: The Nikon FG Camera (with zoom lens and flash) is really 4 superb cameras in 1...providing the photographer with programmed, manual, automatic and TTL (through the lens) flash modes for maximum flexibility and creativity. **2nd Prize:** Leitz Trinovid® 10 x 25 BCA Binoculars have a slim prism design. All metal construction with rubber covering provides noise suppression and shock absorbtion. Compact (4.3 inches) and light (8.4 ounces), you can take them anywhere. **3rd Prizes: (5)** The versatile Halleyscope® features an 8-32x zoom, 2 viewing modes, and all glass optics. Comes complete with camera adaptor, tripod, instruction manual and lifetime warranty. *Plus over 200 additional prizes.*

Here's an exciting opportunity for you to do a big favor for some chosen friends...and possibly do a very big favor for yourself as well.

It's *Natural History's* "View the World" Sweepstakes – and you could end up the winner of a dream vacation for two in exotic Hawaii, or any of the other fabulous prizes.

Hawaii's endless beaches and booming surf...Mauna Loa and other volcanoes...historic Pearl Harbor – these and all of the Islands' other attractions could be yours to enjoy.

And the Sweepstakes is easy to enter. Just return the postpaid reply card accompanying this announcement, printing your name and address in the space provided. At the same time, we ask that you help "spread the word" about *Natural History* and about the Museum in 2 different ways...

1) Give a one-year gift subscription to *Natural History* – including Associate Membership in the Museum – to one or more friends. Your first gift (or your own new or renewal subscription) is $20; all additional gifts are just $14 each.
2) Give us the names of some friends who share your interest in natural history, so we can send them individual invitations to Membership. There is no obligation, whatsoever, if they decide not to join.

When we get your card, we'll enter it in the grand prize drawing. And we'll immediately notify you if you win.

But remember – the card can't make you a winner if you don't send it in. So don't pass up the chance at a dream vacation in Hawaii or any of the other fabulous prizes. Mail the card today.

OFFICIAL SWEEPSTAKES RULES

No purchase required. Winners will be selected in random drawings under the supervision of VENTURA ASSOCIATES, INC., an independent judging organization whose decisions are final. All entries must be received by November 31, 1985. All prizes are guaranteed to be awarded. Odds of winning are determined by the total number of eligible entries received.

Sweepstakes open to residents of the United States, 18 years of age or older except employees and their families of the American Museum of Natural History, their advertising and production agencies, and VENTURA ASSOCIATES, INC. Early Bird prizes will be awarded from all entries received by the date shown elsewhere in this offer. Winners will be notified by mail. Major winners will be required to sign an affidavit of eligibility/publicity release which must be returned within 21 days of date on notification. This sweepstakes may be offered in different creative presentations along with various methods of entry. Travel subject to space and departure availablity and must be completed by May 31, 1986. Taxes are the responsibility of winners. No substitution for prizes except as may be necessary due to availability. Void where prohibited or restricted by law. All federal, state and local regulations apply.

For a list of major prize winners, send a stamped self-addressed envelope to: View the World Winners List, P.O. Box 766, Lowell, IN 46399

*Vacation must be taken before May 1986 and not during peak travel times.

To Be a Platypus

Although it com'st in such a questionable shape, this animal, above all, is true to itself

by Stephen Jay Gould

Long ago, garrulous old Polonius exalted brevity as the soul of wit, but later technology, rather than sweet reason, won his day and established verbal condensation as a form of art in itself. The telegram, sent for cash on the line and by the word, made brevity both elegant and economical—and the word *telegraphic* entered our language for a style that conveys bare essentials and nothing else.

The prize for transmitting most meaning with least verbosity must surely go to the British officer who subdued the Indian province of Sind and announced his triumph, via telegram to his superiors in London, with the minimal but fully adequate "*Peccavi.*" (This tale, in its own telegraphic way, speaks volumes about the social order and education of imperial Britain. In an age when all gentlemen studied Latin, and could scarcely rise in government service without a boost from the old boys of similar background in appropriate public schools, the officer never doubted that his superiors would remember the first person past tense of the verb *peccare*—and would properly translate his message and pun: I have sinned.)

The most famous telegram from my profession did not quite reach this admirable minimum, but it must receive honorable mention for conveying a great deal in few words. In 1884 (I meant to write this column last year to catch the centenary), W.H. Caldwell, a young Cambridge biologist, sent his celebrated telegram from Australia to a triumphant reading at the Annual Meeting of the British Association in Montreal. Caldwell wired: "Monotremes oviparous, ovum meroblastic."

This message may lack the ring of *peccavi* and might be viewed by the uninitiated as pure mumbo jumbo. But all professional biologists could make the translation and recognize that Caldwell had solved a particularly stubborn and vexatious problem of natural history. In essence, his telegram said: the duckbilled platypus (and its relative, the spiny echidna) lays eggs.

(Each word of Caldwell's telegram needs some explication. Oviparous animals lay eggs, while viviparous creatures give birth to live young; ovoviviparous organisms form eggs within their bodies, and young hatch inside their mothers. Sorry for the jargon so early in the column, but these distinctions become important later on. Monotremes are that most enigmatic group of mammals from the Australian region—including the spiny echidna, actually two separate genera of anteaters, and the duckbilled platypus, an inhabitant of streams and creeks. An ovum is an egg cell, and meroblastic refers to a mode of cleavage, or initial division into embryonic cells, after fertilization. Yolk, the egg's food supply, accumulates at one end of the ovum, called the vegetal pole. Cleavage begins at the other end, called the animal pole. If the egg is very yolky, the cleavage plane cannot penetrate and divide the vegetal end. Such an egg shows incomplete, or meroblastic, cleavage—division into discrete cells at the animal pole but little or no separation at the yolky end. Egg-laying land vertebrates, reptiles and birds, tend to produce yolky ova with meroblastic cleavage, while most mammals show complete, or holoblastic, cleavage. Therefore, in adding "ovum meroblastic" to "monotremes oviparous," Caldwell emphasized the reptilian character of these paradoxical mammals—not only do they lay eggs but the eggs are typically reptilian in their yolkiness.)

The platypus surely wins first prize in anybody's contest to identify the most curious mammal. Harry Burrell, author of the classic volume on this paradox (*The Platypus: Its Discovery, Position, Form and Characteristics, Habits and Life History,* Sydney, Angus and Robertson, 1927) wrote: "Every writer upon the platypus begins with an expression of wonder. Never was there such a disconcerting animal!" (I guess I just broke tradition by starting with the sublime *Hamlet.*)

The platypus sports an unbeatable combination for strangeness: first, an odd habitat with curiously adapted form to match; second, the real reason for its special place in zoological history—its enigmatic mélange of reptilian (or birdlike), with obvious mammalian, characters. Ironically, the feature that first suggested premammalian affinity—the "duckbill" itself—supports no such meaning. The platypus's muzzle (the main theme of this column) is a purely mammalian adaptation to feeding in fresh waters, not a throwback to ancestral form—although the duckbill's formal name embodies this false interpretation: *Ornithorhynchus anatinus* (or the ducklike bird snout).

Chinese taxidermists had long fooled (and defrauded) European mariners with the heads and trunks of monkeys stitched to the hind parts of fish—one prominent source for the persistence of mermaid legends. In this context, one can scarcely blame George Shaw for his caution in first describing the platypus (1799):

> Of all the Mammalia yet known it seems the most extraordinary in its conformation, exhibiting the perfect resemblance of the beak of a Duck engrafted on the head of a quadruped. So accurate is the similitude, that, at first view, it naturally excites the idea of some deceptive preparation.

But Shaw could find no stitches, and the skeleton was surely discrete and of one functional piece (the premaxillary bones of the upper jaw extend into the bill and

rovide its major support—no one had rafted a duck onto a beaver). Shaw concluded:

)n a subject so extraordinary as the resent, a degree of scepticism is not only ardonable but laudable; and I ought perhaps to acknowledge that I almost doubt ne testimony of my own eyes with respect o the structure of this animal's beak; yet nust confess that I can perceive no appearnce of any deceptive preparation . . . nor an the most accurate examination of exert anatomists discover any deception.

But if the bill had been a come-on, the ear end provided numerous, and legitiate, reasons for amazement. The platyus sported only one opening, the cloaca, or all excretory and reproductive busiess (as in reptiles, but not most mamals, with their multiplicity of orifices for irth and various forms of excretion. Monotremata, or one-holed, the technical ame for the platypus and allied echidna, onors this unmammalian feature).

Internally, the puzzle only increased. The oviducts did not unite into a uterus, ut extended separately into the cloacal ube. Moreover, as in birds, the right vary had become rudimentary, and all gg cells formed in the left ovary. This onfiguration obviously led to a most troubling hypothesis for biologists committed, s most were in these pre-Darwinian days, o the division of nature into unambiguus, static categories: no uterus, no interal space to form a placenta, a reproductive tract reptilian in form. All this uggested the unthinkable for a mamnal—birth from eggs. The neighboring narsupials, with their pouches and tiny joys, had already compromised the noble ame of mammal. Would Australia also ield the ultimate embarrassment of fur rom eggs?

As anatomists studied this creature

Fitness Master LT-35

TOTAL SYSTEM FOR CARDIOVASCULAR FITNESS.

Simulates cross-country skiing, regarded by fitness authorities as the top cardiovascular exercise. Rated higher than jogging, swimming, biking or rowing.

- Fluid motion — no jarring impact on bones and joints. Avoids running related injuries.
- Excellent for weight control and body tone.
- Stable, unit rests flat on floor. Lightweight for portability. Weighs only 35 lbs.
- Easily stored. Folds to 5 inch height. Slips under a bed or stands upright in closet.
- 30 day home trial. 2 year warranty.
- Can be used by men and women regardless of size or weight. Height and resistance adjustable.

early in the nineteenth century, the mystery only deepened. The platypus looked like a perfectly good mammal in all "standard" nonreproductive traits. It sported a full coat of hair and the defining anatomical signature of mammals—one bone, the dentary, in its lower jaw and three, the hammer, anvil, and stirrup, in its middle ear. (Reptiles have several jawbones and only one ear bone. Two reptilian jawbones became the hammer and anvil of the mammalian ear.) But its premammalian characters extended beyond the reproductive system. In particular, the platypus grew an interclavicle bone in its shoulder girdle—a feature of reptiles but shared by no placental mammal.

What could this curious mélange be, beyond a divine test of faith and patience? Debate centered on modes of reproduction, for eggs had not yet been found and Caldwell's telegram lay half a century in the future. All three possibilities boasted their vociferous and celebrated defenders—for no great biologist could avoid such a fascinating creature and all leaders of natural history entered the fray. Meckel, the great German anatomist, and his French colleague Blainville predicted viviparity, argued that eggs would never be found, and accommodated the monotremes among ordinary mammals. E. Home, who first described the platypus in detail (1802), and the renowned English anatomist Richard Owen chose the middle pathway of ovoviviparity and argued that failure to find eggs indicated their dissolution within the female's body. But the early French evolutionists, Lamarck and Etienne Geoffroy Saint-Hilaire, insisted that anatomy could not lie and that the platypus must be oviparous. Eggs, they argued, would eventually be found.

Geoffroy, by the way, coined the name *monotreme* in an interesting publication that reveals as much about French social history as *peccavi* indicated for imperial Britain. This issue of the *Bulletin des sciences* is labeled *Thermidor, an 11 de la République*. With revolutionary fervor at its height, France broke all ties with the old order and started counting again from year one (1793). They also redivided the year into twelve equal months, with a few days left over for annual rejoicing, and renamed the months to honor the weather rather than old gods and emperors. Thus, Geoffroy named the monotremes in a summer month (Thermidor) during the eleventh year (1803) of the Republic.

Just one incident in the pre-Caldwell wars will indicate the intensity of nineteenth-century debate about platypuses and the relief at Caldwell's resolution. When the great naturalists delineated their positions and defined the battleground, mammary glands had not been found in the female platypus—an apparent argument for those, like Geoffroy, who were trying to distance monotremes as far as possible from mammals. Then, in 1824, Meckel discovered mammary glands. But since platypuses never do anything by the book, these glands were peculiar enough to spur more debate rather than conciliation. The glands were enormous, extending nearly from the forelegs to the hind limbs—and they led to no common opening, for no nipples could be found. (We now know that the female excretes milk through numerous pores onto a portion of her ventral surface, where the baby platypus laps it up.) Geoffroy, committed to oviparity and unwilling to admit anything like a mammalian upbringing, counterattacked. Meckel's glands, he argued, were not mammary but homologs of the odiferous flank glands of shrews, secreting substances for attraction of mates. When Meckel then expressed a milky substance from the mammary gland, Geoffroy admitted that the secretion must be food of some sort, but not milk. The glands, he now argued, are not mammary but a special feature of monotremes, used to secrete thin strands of mucus that thicken in water to provide food for young hatched from the undiscovered eggs.

Owen then counterattacked to support Meckel for three reasons: the glands are largest shortly after the inferred time of birth (though Geoffroy expected the same for mucus used in feeding); the female echidna, living in sand and unable to thicken mucus in water, possesses glands of the same form. Finally, Owen suspended the secretion in alcohol and obtained globules, like milk, not angular fragments, like mucus (an interesting commentary upon the rudimentary state of chemical analysis during the 1830s).

Geoffroy held firm—both to oviparity (correctly) and to the special status of feeding glands (incorrectly, for they are indeed mammary). In 1822, Geoffroy formally established the Monotremata as a fifth class of vertebrates, ranking equally with fishes, reptiles (then including amphibians), birds, and mammals. We may view Geoffroy as stubborn and we certainly now regard the monotremes as mammals, however peculiar—but he presents a cogent and perceptive argument well worth our attention. Don't shoehorn monotremes into the class Mammalia to make everything neat and foreclose discussion, he pleads. Taxonomies are guides to action, not passive devices for ordering. Leave monotremes separate and in uncomfortable limbo—"which suggests the necessity of further examination [and] is far better than an assimilation to normality, founded on strained and mistaken relations, which invites indolence to believe and slumber" (letter to the Zoological Society of London, 1833).

Geoffroy also kept the flame of oviparity alive, arguing that the cloaca and reproductive tract bore no other interpretation: "Such as the organ is, such must be its function; the sexual apparatus of an oviparous animal can produce nothing but an egg." So Caldwell arrived in Australia in September 1883—and finally resolved the great debate, eighty years after its inception.

Caldwell, though barely a graduate, proceeded in the grand imperial style (he soon disappeared from biological view and became a successful businessman in Scotland). He employed 150 aboriginals and collected nearly 1,400 echidnas—quite a hecatomb for monotreme biology. On the subject of social insights, this time quite uncomfortable, Caldwell described his colonial style of collecting:

> The blacks were paid half-a-crown for every female, but the price of flour, tea, and sugar, which I sold to them, rose with the supply of Echidna. The half-crowns were therefore, always just sufficient to buy food enough to keep the lazy blacks hungry.

It was, of course, often done—but rarely said so boldly and without apology. In any case, Caldwell eventually found the eggs of the platypus (usually laid two at a time and easily overlooked at their small size of less than an inch in length).

Caldwell solved a specific mystery that had plagued zoology for nearly a century but he only intensified the general problem. He had proved irrevocably that the platypus is a mélange, not available for unambiguous placement into any major group of vertebrates. Geoffroy had been right about the eggs; Meckel about the mammary glands.

The platypus has always suffered from false expectations based on human fables. (This column discusses the two stages of this false hoping, and then tries to rescue the poor platypus in its own terms.) During the half-century between its discovery and Darwin's *Origin of Species*, the platypus endured endless attempts to deny or mitigate its true melange of characters associated with different groups of vertebrates. Nature needed clean categories established by divine wisdom. An animal could not both lay eggs and feed its young with milk from mammary glands. So Geoffroy insisted upon eggs and no milk; Meckel upon milk and live birth.

Caldwell's discovery coincided with the enty-fifth anniversary of Darwin's *Ori- n.* By this time, evolution had made the ea of intermediacy (and mélanges of iaracters) acceptable, if not positively in- iguing. Yet, freed of one burden, the atypus assumed another—this time im- osed by evolution, the very idea that had st liberated this poor creature from un- ongenial shoving into rigid categories. he platypus, in short, shouldered (with s interclavicle bone) the burden of prim- iveness. It would be a mammal, to be ire—but an amoeba among the gods; a wdry, pitiable little fellow weighted own with the reptilian mark of Cain.

Caldwell dispatched his epitome a cen- ıry ago, but the platypus has never es- aped. I have spent the last week as a early full-time reader of platypusology. Vith a few welcome exceptions (mostly mong Australian biologists who know the reature intimately), nearly every article lentifies something central about the latypus as undeveloped or inefficient rel- tive to placental mammals—as if the un- oubted presence of premammalian char- cters condemns each feature of the platy- us to an unfinished, blundering state.

Before I refute the myth of primitive- ess for the platypus in particular, I hould discuss the general fallacy that quates early with inefficient and still un- erlies so much of our failure to under- tand evolution properly. The theme has irculated through these columns for ears—ladders and bushes. But I try to rovide a new twist here—the basic dis- nction between *early branching* and *un- eveloped,* or *inefficient, structure.*

If evolution were a ladder toward rogress, with reptiles on a rung below ammals, then I suppose that eggs and an nterclavicle would identify platypuses as ntrinsically wanting. But the Old Testa- ent author of Proverbs, though speaking f wisdom rather than evolution, provided he proper metaphor, *etz chayim:* she is a *ree of life* to them who take hold upon er. Evolution proceeds by branching, and ot (usually) by wholesale transformation nd replacement. Although a lineage of eptiles did evolve into mammals, reptiles emain with us in all their glorious abun- ance of snakes, lizards, turtles, and croc- diles. Reptiles are doing just fine in their wn way.

The presence of premammalian charac- ers in platypuses does not brand them as nferior or inefficient. But these charac- ers do convey a different and interesting nessage. They do signify an early branch- ng of monotreme ancestors from the ineage leading to placental mammals. This lineage did not lose its reptilian char-

Collect Authentic Dinosaur Models from the British Museum of Natural History

THE COMPLETE SET **$14.95** BY MAIL ONLY

These are not toys.

You are looking at four authentic dinosaur models designed by the curators of the British Museum of Natural History. Each was sculptured to scale (1:45) by the craftsmen of the Museum duplicating the original down to the skin texture! They have been beautifully reproduced in solid, unbreakable, self-colored plastic in sizes as large as 19½ inches! Thousands of these fascinating and educational, life-like models have been sold by Museums throughout the world. We are proud to offer them to collectors for the very first time through this advertisement.

Set includes Diplodocus, 19½"; Tyrannosaurus, 10"; Triceratops, 6"; Stegosaurus, 5". Only $14.95 for all four, including detailed description and history of each. Sold with an unconditional 30 day moneyback guarantee.

acters all at once, but in the halting and piecemeal fashion so characteristic of evolutionary trends. A branch that split from this central lineage after the defining features of mammals had evolved (hair and an earful of previous jawbones, for example) might retain other premammalian characters (birth from eggs and an interclavicle) as a sign of early derivation, not a mark of backwardness.

The premammalian characters of the platypuses only identify the antiquity of their lineage as a separate branch of the mammalian tree. If anything, this very antiquity might give the platypus more scope (that is, more time) to become what it really is, in opposition to the myth of primitivity: a superbly well-designed creature for a particular, and unusual, mode of life. The platypus is an elegant solution for mammalian life in streams—not a primitive relic of a bygone world. Old does not mean hidebound in a Darwinian world.

Once we shuck the false expectation of primitiveness, we can view the platypus more fruitfully as a bundle of adaptations. Within this appropriate theme of *good* design, we must make one further distinction between shared adaptations of all mammals and particular inventions of platypuses. The first category includes a coat of fur well adapted for protecting platypuses in the (often) cold water of their streams (the waterproof hair even traps a layer of air next to the skin, thus providing additional insulation). As further protection in cold water and on the same theme of inherited features, platypuses can regulate their body temperatures as well as most "higher" mammals, although the assumption of primitivity stalled the discovery of this capacity until 1973—before that, most biologists had argued that platypus temperatures plummeted in cold waters, requiring frequent returns to the burrow for warming up. (My information on the ecology of modern platypuses comes primarily from Tom Grant's excellent book, *The Platypus,* New South Wales University Press, 1984, and from conversations with Frank Carrick in Brisbane. Grant and Carrick are Australia's leading professional students of platypuses, and I thank them for their time and care.)

These features, shared by passive inheritance with most other animals, certainly benefit the platypus, but they provide no argument for my theme of direct adaptation—the replacement of putative primitivity by a view of the platypus as actively evolving in its own interest. Many other features, however, including nearly everything that makes the platypus so distinctive, fall within the second category of special invention.

Platypuses are relatively small mammals (the largest known weighed just over five pounds and barely exceeded two feet from tip to tail). They construct burrows in the banks of creeks and rivers: long (up to sixty feet) for nesting; shorter for daily use. They spend most of their life in the water, searching for food (primarily insect larvae and other small invertebrates) by probing into bottom sediments with their bills.

The special adaptations of platypuses have fitted them in a subtle and intricate way for aquatic life. The streamlined body moves easily through water. The large, webbed forefeet propel the animal forward by alternate kicks, while the tail and partially webbed rear feet act as rudders and steering devices (in digging a burrow, the platypus anchors with its rear feet and excavates with its forelimbs). The bill works as a feeding structure par excellence, as I shall describe in a moment. Other features undoubtedly serve in the great Darwinian game of courtship, reproduction, and rearing—but we know rather little about this vital aspect of platypus life. As an example, males bear a sharp, hollow spur on their ankles, attached by a duct to a poison gland in their thighs. These spurs, presumably used in combat with competing males, grow large during the breeding season. In captivity, males have killed others with poison from their spurs, and many platypuses, both male and female, sport distinctive punctures when captured in the wild.

Yet even this long and impressive list of special adaptations has been commonly misrepresented as yet another aspect (or spinoff) of pervasive primitiveness. Burrell, in his classic volume (1927), actually argued that platypuses develop such complex adaptations because simple creatures can't rely upon the flexibility of intelligence and must develop special structures for each required action. Burrell wrote:

> Man . . . has escaped the need for specialization because his evolution has been projected outside himself into an evolution of tools and weapons. Other animals in need of tools and weapons must evolve them from their own bodily parts; we therefore frequently find a specialized adaptation to environmental needs grafted on to primitive simplicity of structure.

You can't win in such a world. You are either primitive prima facie or specialized as a result of lurking and implicit simplicity! From such a Catch-22, platypuses can only be rescued by new concepts, not additional observations.

As a supreme irony, and ultimate defense of adaptation versus ineptitude, the structure that built the myth of primitivity—the misnamed duckbill itself—represents the platypus's finest special invention. The platypus bill is not a homolog of any feature in birds. It is a novel structure uniquely evolved by monotremes (the echidna carries a different version as its long and pointed snout). The bill is not simply a hard, inert horny structure. Soft skin covers the firm substrate, and this skin houses a remarkable array of sensory organs. In fact, and strange to tell, the platypus, when under water, shuts down all its other sensory systems and relies entirely upon its bill to locate obstacles and food. A flap of skin covers the tiny eyes and nonpinnate ears when a platypus dives, while a pair of valves closes off the nostrils under water.

E. Home, in the first monograph on platypus anatomy (1802), made an astute observation that correctly identified the bill as a complex and vital sensory organ. He dissected the cranial nerves and found almost rudimentary olfactory and optic members but a remarkably developed trigeminal, carrying information from the face to the brain. With great insight Home compared the platypus bill to a human hand in function and subtlety (Home never saw a live platypus and worked only by inference from anatomy). He wrote:

> The olfactory nerves are small and so are the optic nerves; but the fifth pair which supplies the muscles of the face are uncommonly large. We should be led from this circumstance to believe, that the sensibility of the different parts of the bill is very great, and therefore it answers to the purpose of a hand, and is capable of nice discrimination in its feeling.

Then, in the same year as Caldwell discovered eggs, the English biologist E.E. Poulton found the primary sensory organ of the bill. He located numerous columns of epithelial cells, each underlain by a complex of neural transmitters. He called them "push rods," arguing by analogy with electrical bells that a sensory stimulus (a current of water or an object in bottom sediments) would depress the column and ignite the neural spark.

A set of elegant experiments in modern neurophysiology by R.C. Bohringer and M.J. Rowe (*Journal of Comparative Neurology,* vol. 177, 1977, and *Australian Mammalogy,* vol. 4, 1981) can only increase our appreciation for the finely tuned adaptation of the platypus bill. They found Poulton's rods over the bill's entire surface, but four to six times more densely packed at the anterior border of the upper bill, where platypuses must first encounter obstacles and food items. They noted different kinds of nerve recepto

nder the rods, suggesting that platypuses
n distinguish varying kinds of signals
erhaps static versus moving components
· live versus dead food). Although indi-
dual rods may not provide sufficient in-
rmation for tracing the direction of a
imulus, each rod maps to a definite loca-
on on the brain, strongly implying that
ie sequence of activation among an array
f rods permits the platypus to identify the
ze and location of objects.

Neurophysiologists can locate areas of
ie brain responsible for activating defi-
ite parts of the body and draw a "map" of
ie body upon the brain itself. (These ex-
eriments proceed from either direction.
)ne either stimulates a body part and
ecords the pattern of activity in a set of
lectrodes implanted into the brain or one
ulses a spot on the brain and determines
ie resulting motion of body parts.) We
ave no finer demonstrations of evolution-
ry adaptation than numerous brain maps
hat record the importance of specially de-
eloped organs by their unusually en-
arged areas of representation upon the
ortex. Thus, a raccoon's brain map dis-
lays an enormous domain for its fore-
aws, a pig's for its snout, a spider mon-
ey's for its tail. Bohringer and Rowe have
dded the platypus to this informative ar-
ay. A map of the platypus's brain is
nostly bill.

We have come a long way from the first
rominent evolutionary interpretation
ver presented for the platypus bill. In
844, in the major pre-Darwinian defense
f evolution written in English, Robert
Chambers tried to derive a mammal from
bird in two great leaps, via the interme-
liate link of a duckbilled platypus. One
tep, Chambers wrote,

vould suffice in a goose to give its progeny
he body of a rat, and produce the orni-
horhynchus, or might give the progeny of
n ornithorhynchus the mouth and feet of a
rue rodent, and thus complete at two
tages the passage from the aves to the
nammalia.

The platypus, having suffered such
lings and arrows of outrageous fortune in
mposed degradation by human hands,
as cast its arms (and its bill) against a sea
f troubles and vindicated itself. The
vhips and scorns of time shall heal. The
ppressor's wrong, the proud man's con-
umely have been reversed by modern
tudies—enterprises of great pith and mo-
nent. The platypus is one honey of an ad-
ptation.

Where's the Gas?

Recent observations on elliptical galaxies contradict previous basic beliefs

by Stephen P. Maran

Elliptical galaxies include the largest star systems yet discovered, as well as many small ones. They are one of the four principal types of galaxies—the so-called island universes of billions or perhaps trillions of stars. (The other three types are spirals, spheroidals, and irregulars.)

Unlike our Milky Way and the Andromeda, which are spiral galaxies, ellipticals have no spiral arms and few or no bright nebulae (interstellar clouds of hot gas and dust) or bright young blue stars. Because ellipticals seemed to contain little, if any, interstellar gas and dust—the basic materials from which stars are born—astronomers dismissed them as dead galaxies in which star formation ended billions of years ago. Also unlike the spiral galaxies, the ellipticals do not have a disk—a flat system of stars and nebulae. On photographic maps they are shaped like ellipses and their brightness decreases smoothly from the center to the outskirts. "The star distribution in an elliptical galaxy is uncannily smooth," remarked British cosmologist Fred Hoyle.

Elliptical galaxies seem to have an enormous range of sizes. Some, like M32, a dwarf companion of the great Andromeda spiral, are tiny, with diameters of 10,000 light-years or less; others, like M87 in Virgo, are giants, some exceeding 150,000 light-years in size. (A light-year is the distance traversed at the speed of light in a vacuum over an interval of one year. One light-year equals about 5.8 trillion miles.) You can see M32 in most astronomy books, as a minor object in photographs of Andromeda; M87 is pictured about as often, usually to show the spectacular blue jet that emanates from its center.

Other than the contrast in form, the most pronounced difference between elliptical and spiral galaxies is the general lack of gas, dust, and hot young stars in ellipticals. At least, that's what astronomers believed until recently. For example, observations made in February 1974 with the 140-foot radio telescope at the National Radio Astronomy Observatory in Green Bank, West Virginia, showed that neutral hydrogen, a gas in which each atom consists of one proton and one electron, makes up no more than one-tenth of one percent of the mass of elliptical galaxies, although it is a principal constituent of the interstellar matter in the Milky Way. The survey scientists, John S. Gallagher, Sandra M. Faber, and Bruce Balick, concluded that the severe deficiency of neutral hydrogen in elliptical galaxies "is consistent with other observed features," including the lack of dust lanes (the dark streaks that cross the disks of spiral galaxies) and bright nebulae, all indicating "that little interstellar matter is present." In spiral galaxies, on the other hand, clouds of gas and dust and groups of hot young stars dot the spiral arms and make them readily apparent. Since new stars form in the interstellar clouds of the Milky Way, astronomers concluded that elliptical galaxies were no longer forming stars.

In 1976, Faber and Gallagher again explored the issue of the missing interstellar gas. They wanted to see if the gas was somehow hidden from view or if it had been removed from the galaxies. On balance, they concluded, the gas had been removed, probably by a galactic wind, a phenomenon whose existence was proposed in 1971 by two California astrophysicists, William G. Mathews and James C. Baker.

Earlier investigators believed that the gas and dust in elliptical galaxies had been used up in the formation of stars. However, as we study the stars in the Milky Way, we find that they tend to shed gas in the form of winds or puffs from explo sions; gas is also shed during the expulsion of the stars' outer layers, producing so called planetary nebulae, such as the Ring nebula in the constellation Lyra. Our own sun produces the solar wind, a constant outpouring of electrified gas; and red gi ant stars have much stronger winds, which blow huge amounts of gas out into space Dust particles also seem to form in the cooling gases expelled from red giant stars. Thus, in the Milky Way, gas and dust beget stars that shed more gas and dust, which beget more stars.

According to Mathews and Baker, the total amount of gas released into interstellar space in a large elliptical galaxy through winds from red giant stars, the formation of planetary nebulae, and other causes, must amount to between one-tenth the mass of our sun to a full solar mass per year. At that rate, a billion or more solar masses of interstellar gas should have collected in the large elliptical galaxies since the formation of all galaxies early in the history of the universe. However, even in 1971, before the Gallagher survey, scientists knew that large amounts of gas were not present in elliptical galaxies. Mathews and Baker explained this discrepancy by proposing that "gas ejected from stars in elliptical galaxies is heated by supernova explosions and produces outward-flowing galactic winds."

In past years, whenever a study revealed the presence of some gas or dust or even evidence for young stars in an elliptical galaxy, the galaxy in question was dismissed as an oddball, an exception that proved the rule that ellipticals have no new stars because they lack the raw materials needed to make them. Thus, the jet ejection in M87, though gaseous, was re

HOW TO READ IN THE SUN WITHOUT GETTING BURNED

Join QPB this summer and you'll stop getting burned by hardcover prices.

Because QPB books cost up to 65% less than their hardcover counterparts. QPB books are softcover editions in hardcover sizes. They're durably bound and printed on fine paper.

And to start, you can choose any three books on this page for just a dollar each. Choose from fiction, nonfiction, science, history, art and more. And you're under no obligation to buy another book. Ever.

So join QPB and you'll have it made in the shade.

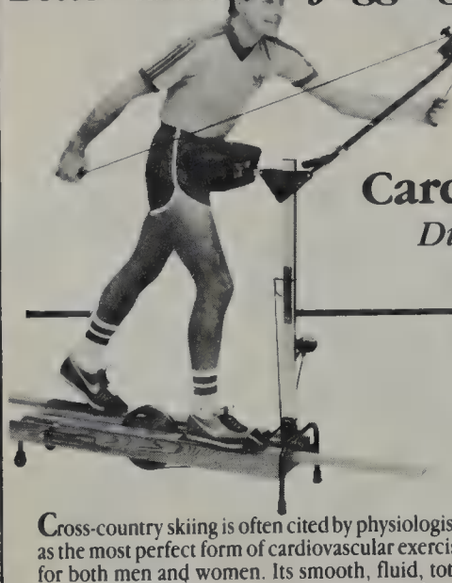
The first book club for smart people who aren't rich.

Better than Jogging, Swimming, or Cycling...



NordicTrack

Jarless Total Body

Cardiovascular Exerciser

Duplicates X-C Skiing for the Best Motion in Fitness

Cross-country skiing is often cited by physiologists as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles so higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the pleasant X-C skiing motion and provides the same cardiovascular endurance-building benefits–right in the convenience of your home, year 'round. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

More Complete Than Running

NordicTrack gives you a more complete work out–conditions both upper body and lower body muscles at the same time. Fluid, jarless motion does not cause joint or back problems.

More Effective Than Exercise Bikes

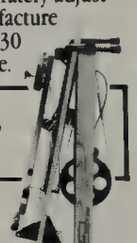
NordicTrack's stand-up skiing motion more uniformly exercises the large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass.

Even Better Than Swimming

NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. When swimming, the body is supported by the water, thus preventing these muscles from being effectively exercised. The stand up exercising position on the NordicTrack much more effectively exercises these muscles.

A Proven, High Quality Durable Product

NordicTrack is in its 7th year of production. NordicTrack is quiet, motorless and has separately adjustable arm and leg resistances. We manufacture and sell direct. Two year warrantee, 30 day trial period with return privilege.



Folds and stands on end to require only 15" x 17" storage space.

garded as a symptom of a rare phenomenon at the center of the galaxy, perhaps involving a giant black hole.

Recently, new evidence has shown that these old ideas are wrong. Dust lanes, for example, are caused by dust clouds that cut off light from the stars beyond. Even though a few dust lanes were detected in elliptical galaxies years ago, they were thought to be extreme rarities. Last year, however, two astronomers from Munich reported at a French conference on galaxies that dust lanes are actually common in nearby elliptical galaxies. Recent photographs from a Schmidt telescope in Chile, they found, show traces of dust lanes in these galaxies. Since it is impossible to detect dust lanes on current telescopic photographs of more distant ellipticals, we don't know whether they are present in these galaxies. But once NASA's Hubble Space Telescope is launched in 1986, we will know more. The telescope's photographs will be at least ten times sharper than those taken by today's ground-based telescopes.

The observations that, above all others, have led to a new understanding of elliptical galaxies were made with Einstein, a satellite observatory launched in 1978 that provided the first fairly sharp X-ray images of galaxies. At first, astronomers who studied the Einstein images concentrated on the properties of X-ray emission from large clusters of galaxies. They found that those emissions often contain an intracluster medium of very hot gas (about 180 million degrees Fahrenheit) which pervades the space between member galaxies of a cluster (see "Clusters of Galaxies," *Natural History*, February 1983). In some cases, the intracluster medium seems to be concentrated toward the center of a cluster, suggesting that the gas is cooling and settling there, a phenomenon known as a cooling flow. In other clusters, elliptical galaxies were found to glow from hot gas of their own, which shines in X-rays because, although it is very thin, it is also very hot. The Einstein-detected gas is so hot that it is fully ionized; in other words, its constituent atoms have each lost at least one electron. Most of the gas is hydrogen, and since hydrogen atoms have only one electron to begin with, which they lose upon ionization, the gas is not neutral. This hydrogen was not detectable by the radio observations employed in the 1974 Gallagher survey; that survey only detected radio emission from *neutral* hydrogen.

The discovery that elliptical galaxies in some clusters contain very hot, ionized hydrogen had unclear implications for another question: whether elliptical galaxies

general contain much gas. The presence f hot gas in the cluster members might, or example, be related to the properties of ie cluster, including its intracluster me- ium.

Last year, three astrophysicists from Cambridge University published a con- incing study of Einstein observations of olated elliptical galaxies (those not lo- ated in clusters). They found that iso- ted ellipticals glow in X-rays just as ome elliptical galaxies in clusters glow. The gas, at a temperature of perhaps 90 illion degrees Fahrenheit, is fully ion- zed, just like the even hotter intracluster edium mentioned above.

Could the hot gas observed in X-rays by he British investigators be the galactic vind postulated by Mathews and Baker? Gas heated by supernova explosions night well be very hot. However, if the ob- erved gas were the putative galactic vind, continuously escaping from the par- nt elliptical galaxy, then it would have to e replenished by the release of about ten olar masses of gas per year from red gi- nts and other stars in the galaxy. And this quantity is at least ten times larger than what the star population of a large ellipti- al galaxy can provide. In other words, the X-ray emission requires much more gas than can remain in an elliptical galaxy constantly subject to an outflowing galactic wind.

If the hot gas in isolated elliptical galaxies observed by the Einstein satellite is not escaping as a wind, then it must be cooling as it remains around the galaxy. In that case, some of the gas is probably sinking toward the center of its parent galaxy and becoming denser as it cools. As it thickens, the gas should condense to form new stars. That would explain why observations with visible light and radio telescopes show very little cool gas. Hot gas is observed in X-rays; cool gas, we think, is used up in making stars.

If new stars are forming in elliptical galaxies, why don't we find groups of bright, hot young stars in them, as we do in the Milky Way and other spiral and irregular galaxies? Although the hot young stars are very massive compared to the sun, they are rare. Most stars, in fact, are less massive than the sun. The more massive a normal star is, the brighter it shines as a result of nuclear reactions in its interior. In most galaxies in which star formation has been studied, we cannot pick out less conspicuous individuals—the medium- and low-mass stars comparable in size to our sun. If we could pick them out, we would find it difficult to say whether they were very young, since stars like the sun are changing very slowly, whereas massive stars run through their lives in only a few million years. Newly formed stars in elliptical galaxies cannot be massive, since they would be observed but are not. Instead, they may be the size of the sun or even smaller.

The Einstein evidence demonstrates that elliptical galaxies contain hot gas, readily detectable only with X-ray telescopes. As the gas cools, it is probably consumed in the formation of new stars. Under the circumstances in which gas cools and condenses in ellipticals, however, the kind of massive, young stars that we could actually hope to detect apparently form rarely, if ever.

New stars of modest mass may well be forming in elliptical galaxies, but at present no known technique can detect and identify them. Accordingly, elliptical galaxies may be evolving star systems after all—not mere fossil remnants of an ancient epoch of star birth.

EXPLORE NEW WORLDS

Astronomy is the only science that goes from spectator science to participation in as little as five minutes. It's fun to read about astronomical explorations. It's more fun to pick up your telescope, carry it outside and explore for yourself. You'll see nebulae, galaxies, star clusters, the rings of Saturn, the jewel-like moons of Jupiter, the vivid lunar landscape.

Celestron — world's leading manufacturer of modern telescopes — offers a line of superb refractors from 60mm to 102mm. Our popular C80 is shown above. Each Celestron refractor offers high contrast views, precision optics, an excellent equatorial mount, slow motion controls (optional computer control) and Celestron's lifetime limited warranty.

Find out how easy and exciting astronomy can be. Call or contact Celestron today. New worlds are waiting.

PRECISION OPTICS

When Three Equals Four

by Thomas D. Nicholson

Here's a puzzle: How can three planets give us two bright objects in the evening and two bright objects in the morning? Easy—when one of them is Jupiter and it's just past opposition. In August, we see it both after sunset and before sunrise. While Saturn is in the southwest in the early evening, Jupiter is in the southeast. Saturn sets about three and a half hours after the sun, but Jupiter rises higher, appearing at its highest in the south about midnight. Continuing across the sky in the morning hours, it eventually fades into the twilight of the west before setting shortly before sunrise. Meantime, Venus rises several hours after midnight and appears high and bright in the southeast before the sun comes up.

Jupiter and Venus are easy to recognize as they far outshine any star in the night sky. Jupiter will be the brightest "star" that you will see on August nights until Venus rises in the early morning. Venus, the third brightest celestial object, is more than two and a half times more brilliant than Jupiter and will dominate the southeastern sky for several hours before sunup. Saturn, although not as prominent as Jupiter or Venus, can be easily sighted if you can recognize Scorpius with its hooked tail and the bright reddish star Antares marking the position of its heart. Saturn is in front (to the west) of the Scorpion, nestled between two dimmer stars that were once the Scorpion's claws but are now part of Libra. On the 22d, the moon will pass just below (to the south of) Saturn, making the planet easy to locate. If you have a small telescope with at least 40 power, you will be able to glimpse Saturn's beautiful ring system. At the beginning of August, Mercury will be lost in the sun's glare, but by month's end it may be viewed low in the east just before sunrise.

The following events are given in eastern standard time unless otherwise indicated.

August 1: The moon is one day past full, riding the border between Capricornus and Aquarius across the sky. The bright object within its glow is Jupiter, to its west.

August 2–7: The waning gibbous moon works its way east through the autumn stars, rising with them in the late evening and continually growing thinner and dimmer. Look for the four stars in the Square of Pegasus above the moon this weekend.

August 4: Jupiter has been slowly edging away from the morning and into the evening, and today it makes the jump. Opposite the sun at about 7:00 A.M., it rises slightly before sundown, making it an evening star. But it still has a healthy presence in the dawn.

August 7: Apogee moon (farthest from the earth) is in Aries, marked by the constellation's two well-known stars, Hamal and Sheratan, above it. The moon left the First Point of Aries (the vernal equinox) behind several nights ago.

August 8: Last-quarter moon, still in Aries, is at 1:29 P.M.

August 9–11: The morning moon, a shrinking crescent, moves through Taurus, a constellation we will see in the evening this winter.

August 10: Mercury is at inferior conjunction (between the earth and sun), entering the morning sky.

August 11–13: These are the best mornings for the old faithful of the meteor showers, the Perseids. Expect thirty to fifty meteors per hour (maximum in the postmidnight hours on the night of the 11th into the morning of the 12th, many very bright). Best time to look is from 1:00 to 3:00 A.M.; pick a place where you can comfortably see as much of the sky as possible. The dim light of the waning crescent moon should be no bother.

August 13: Watch the crescent moon crawl away from Venus in the dawn sky. It slipped past the planet about moonrise.

August 16: New moon occurs in Leo at 5:06 A.M.

August 18: You should see the young crescent moon in the southwest after sundown, just above the summer solstice.

August 19: Tonight's crescent moon, near Spica in Virgo, is at perigee (nearest the earth).

August 20: Mercury ends its retrograde slide between the earth and sun. It resumes direct (easterly) motion today.

August 22: The moon is about to pass into Scorpius when it reaches first-quarter phase at 11:26 P.M. The star to its right is Saturn, in Libra.

August 23: The reddish star near tonight's moon is Antares, in the Scorpion. You should easily be able to trace the curved tail of Scorpius below and to the left of the moon.

August 25: The gibbous moon shouldn't be too bright for finding the teapot-shaped group of stars that marks Sagittarius. The peak of the teapot "lid" is just above the moon, the spout is to the right, and the handle to the left.

August 27–28: As it slips east through Capricornus, the gibbous moon passes below Jupiter. The planet is to the moon's left on the 27th, to its right on the 28th.

August 28: Mercury may be viewed in the morning sky of late August, low in the east before sunrise. It's at greatest westerly (to the sun's right) elongation today.

August 30–31: Full moon is on the 30th at 4:27 A.M. The moon spends both days in Aquarius, then slips into Pisces the night of the 31st.

Editor's Note: The Sky Map in the July issue shows the constellations and stars for this month and gives the times for use.

Fill out this coupon and save the children

Complete this simple questionnaire, and befriend a needy child through Save the Children. For only fifty-two cents a day, your money, combined with that of other sponsors, can breathe new life into an impoverished village. . .help hardworking people in their fight for dignity. . .turn despair into hope for a child who has known only disaster. Fifty-two cents may not buy much where you live. But for the poorest of the poor where the need is so desperate, it can work miracles.

My Name Is _____
(please print)

Address _____

City _____ State _____ Zip _____

Tell us how you want to help, by answering these questions:

1. What kind of child would you like to sponsor?

☐ Boy ☐ Girl ☐ Either

2. What geographical area are you interested in?

Urgent need exists in all areas listed below. If you have a strong preference for a particular location, check the area of your choice. If not, won't you please let us assign a child where the need is greatest?

☐ **Certainly. Choose a child for me in an area of greatest need.**

I strongly prefer:

☐ Africa
☐ American Indian
☐ Appalachia (U.S.)
☐ Bangladesh
☐ Colombia
☐ Dominican Republic
☐ Gaza Strip
☐ Honduras
☐ Indonesia
☐ Inner Cities (U.S.)
☐ Israel
☐ Lebanon
☐ Mexico
☐ Nepal
☐ Philippines
☐ Southern States (U.S.)
☐ Southwest Hispanic (U.S.)
☐ Sri Lanka
☐ Thailand

3. Would you like a picture of your sponsored child?

Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.

☐ Yes ☐ No

4. Would you like to exchange correspondence?

If desired, correspondence can help build a meaningful one-to-one relationship. Translations, where necessary, are supplied by Save the Children.

☐ Yes ☐ No

5. Would you like information about the child's community?

Because 50 years of experience has taught us that direct handouts are the least effective way of helping children, your sponsorship contributions are not distributed in this way. Instead they are used to help children in the most effective way possible—by helping the entire community with projects and services, such as health care, education, food production and nutrition. Several times a year you can receive detailed reports on these community activities which provide permanent improvements to the child's environment. Would you like to receive such information?

☐ Yes ☐ No

6. How do you wish to send your sponsorship contribution?

Enclosed is my check for $ _____.

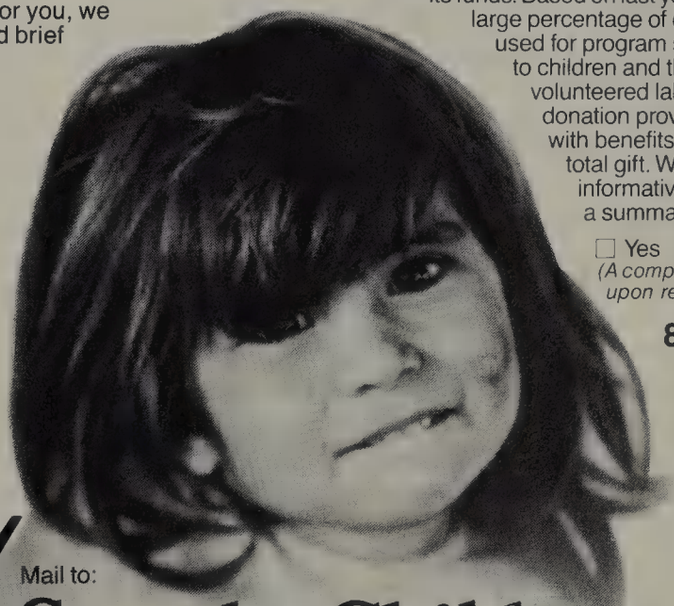
☐ Monthly, $16
☐ Quarterly, $48
☐ Semi-annually, $96
☐ Annually, $192

7. Do you wish verification of Save the Children credentials?

Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?

☐ Yes ☐ No

(A complete audit statement is available upon request.)



8. Would you rather make a contribution than become a sponsor at this time?

☐ Yes, enclosed is my contribution of $ _____.

☐ Check here for general information about our unique programs for aiding impoverished children.

Halley's Comeback

It is still too early to see Comet Halley. That time begins in early December of this year and continues until mid-April 1986, occurring at various intervals during that period. Right now, in August, Halley's comet is still racing toward the sun and is somewhere between Jupiter and Mars, still south of the planetary planes. This month's diagram shows the comet about 273,000,000 miles from the sun, speeding toward it at 47,000 miles per hour, and 322,000,000 miles from the earth and closing with it (because the earth is moving toward the comet as well) at 103,000 miles per hour. It still has three months to go before moving inside the orbit of Mars. While its brightness is now more than doubling from month to month, it is still quite dim and without evidence of form, visible only with well-placed telescopes of sufficiently large aperture. But the time has come to plan how you may be able to see the comet when the time is right and to decide whether you want to see it badly enough to make some effort to improve your chances.

All the evidence confirms that this will not be the bright spectacular comet that history has described for us. There are some clues that the view may be better than first predicted, but not significantly so. The comet may become bright enough to be seen with the naked eye *if* conditions are favorable. But that's a big *if!* . . . if the sky is clear and free of haze and pollution, if the comet is high enough above the horizon, if the moon is down, if the sky in unobstructed by buildings or trees, and if there are no city lights or glare to obscure faint objects.

At the best time for seeing the comet (when it will be brightest in our sky next March and April), it will be deep in the southern sky, well south of the equatorial plane. That means it will be very low in the sky at mid-northern latitudes, which will seriously limit the chance of seeing it. This explains the interest in traveling south. The farther south you go, the higher the comet will be in the sky, until you get to about latitude 20° south. After that, farther travel south won't make much difference.

Even if you plan on going to a more favorable location, don't expect too much of the comet. It will not be any brighter, though it will be higher, easier to see in darker skies, visible for more hours during the night, and—if you choose your trip wisely—you may get professional help from astronomers in finding it. But with or without assistance, the best period for seeing the comet will still be from mid-March to mid-April; the very best time will be after April 3 when there will be the least moonlight.

Another advantage in traveling south in late March or April will be the opportunity to enjoy the riches of the southern sky in late summer and fall (don't forget, seasons are reversed south of the equator). The brightness of the southern Milky Way, the Southern Cross, and nearby Coal Sack, the Clouds of Magellan, and the extension of our bright winter stars down past Canopus will delight you, especially if an experienced stargazer is along to point out the significance of these deep-sky wonders that we never see from up north. If Halley's comet doesn't thrill you by its appearance, the rest of the southern sky should.

A Lasting Tribute to America's Vanishing Breeds...

Presenting a fine, limited-edition porcelain figurine, created by famed American sculptor Roger Brown, and inspired by one of the most intriguing of all wild animals: the blue-eyed, Eastern cougar.

Throughout history, the forces of nature have threatened the survival of some of the world's most interesting and unusual breeds. To focus attention on these endangered species, famed sculptor Roger Brown and River Shore, have produced their first-ever limited-edition collection of animal figurines inspired by ***Babies of Endangered Species.***

After months of research, Brown chose "Sidney" the Eastern cougar to premiere this collection because of his handsome looks and playful manner. This tawny-buff and brown cougar's blue eyes dance as he rolls on his back and toys with a twig. His expressive tail wags between his legs.

It has been three years since Roger Brown has offered a baby animal figurine, and thus the "birth" of "Sidney" is causing a stir among collectors who know that many Brown works – especially his first-issue "Akiku" seal figurine from 1978 – have appreciated significantly in value in the market place.

"Sidney" is the first of eight Roger Brown original sculptures in the ***Babies of Endangered Species*** Figurine Collection – including a baby grizzly bear, a sea otter and five other charming, hand-painted porcelain pieces. As a series subscriber, you will be issued subsequent pieces at intervals of every two months at the guaranteed issue price of $45.00 for each figurine, payable in two convenient installments.

There is no risk to you in ordering now under The Hamilton Collection 100% Buy-Back Guarantee. You may return "Sidney" or any succeeding figurine at any time within 30 days of receipt for a full refund. Each issue will be accompanied by a Certificate of Authenticity, attesting to its status as part of the limited edition of 15,000.

Because the edition is so small compared to the number of Brown and River Shore collectors, and because of the charm and appeal of "Sidney" and the widespread reputation of sculptor Roger Brown, a *prompt sellout is anticipated.* Be sure to return your reservation by the final postmark date to guarantee its consideration. To be safe, order today! The Hamilton Collection, 9550 Regency Square Blvd., P.O. Box 2567, Jacksonville, FL 32232.

FINAL POSTMARK DATE: **August 30, 1985**

Please accept my subscription to the *Babies of Endangered Species* Figurine Collection. Each of the eight figurines is limited to an edition of 15,000, as documented by an accompanying Certificate of Authenticity. The original issue price for each is $45.00 (plus $2.14 postage and handling), payable in two equal installments, with the first installment due prior to shipment. Figurines will be issued approximately every two months.

I prefer to pay the initial installment for my first figurine as follows:

☐ **With this order.** I enclose my initial payment of $23.57*.

☐ **By credit card.** Charge $23.57* to my credit card as follows (check one only):

A Blind Eye on India

Recent media depictions of the raj ignore the sexual exploitation of lower-caste women

by Pauline Kolenda

Last winter's screening season was dominated by sagas of the British in India, with *A Passage to India* at the movies and *The Jewel in the Crown* on television. Both were taken from famous novels, and both stressed a prime taboo of any caste system, the prohibition against lower-caste men—in these cases, Indians—having sexual relations with higher-caste women—in these cases, women of the British rule, the raj. The British horror of any infraction of this prohibition is expressed by accusations of rape in both *Passage* and *Jewel*. Even the possibility of friendliness between an Indian man and a British woman is shown to make members of the two opposing castes uneasy. Adela Quested's friendliness in E.M. Forster's *A Passage to India* (written and set in the 1920s) is confusing to an Indian Moslem man, Nawab Bahadur:

> "How do you do?" said Adela . . . . She held out her hand. The old gentleman judged from so wanton a gesture that she was new to his country, but he paid little heed. Women who exposed their face became by that one act so mysterious to him that he took them at the valuation of their men folk rather than at his own. Perhaps they were not immoral, and anyhow they were not his affair.

And the falsely accused hero-victim of *Jewel*, Hari Kumar, addresses this issue during a prison interrogation set in 1942 (Paul Scott, *The Day of the Scorpion*, published in 1968):

> Miss Manners was a white girl. Her friendliness towards me was of a kind that embarrassed people to watch . . . . Even someone like Lady Chatterjee was incapable of accepting immediately that a white girl could treat an Indian like a man. I found it difficult to accept it myself. For a time I thought she was making fun of me. She talked so readily. Without any kind of artificiality—or so it seemed. Just as if we'd been back home [in England]. Lady Chatterjee very naturally treated me with caution after that . . . .She probably thought I might take advantage of Miss Manners. That's the popular assumption, isn't it? That an Indian will always take advantage of an English person who is friendly.

There is, however, the other side to caste and sexuality in India. As the social psychologist John Dollard pointed out long ago, one of the features of a caste system anywhere is the access upper-caste males have to lower-caste females. While Paul Scott managed to write four lengthy volumes on the British raj with only rare hints at the other side, Rudyard Kipling was less inhibited in discussing it. In his story "Without Benefit of Clergy," he portrays a relationship between a young British official and his beloved Indian consort, and in his famous poem about the road to Mandalay, a Burmese maiden awaits her British soldier-lover.

The British historian Kenneth Ballhatchet, in *Race, Sex and Class under the Raj: Imperial Attitudes and Policies and Their Critics, 1793–1905*, mentions other facts of raj life. British military officers and higher officials were not allowed, or at least not expected, to marry until in their thirties, and marriages with Indian women were officially discouraged. British enlisted men, in contrast, because they were not expected to be able to sublimate their sexual urges as consistently as their officers, were regularly supplied with Indian prostitutes by the authorities (much of Ballhatchet's book describes the attempts to control venereal disease among the prostitutes).

In India, sexual strain between castes was not limited to that between the British as the ruling caste and the Indians as the ruled. Intercaste sexual relationships of all kinds have been a highly charged fact of Indian society, because castes, by definition, are closed communities. Indian castes are hereditary groups that are, above all, endogamous, that is, a person must marry within the caste of his or her birth to remain a fully accepted member. This feature was observed by the Portuguese, who were among the first European colonists of South Asia. The English word *caste* comes from the Portuguese *casta;* the Latin root means pure, or chaste, originally, cut off, or separated (*chaste* derives from the same root).

Marriages in India are virtually all arranged by the elders of the bride's and groom's extended families and caste communities. It is considered sinful for a Hindu father to fail to arrange a marriage for his daughter. In traditional Indian society, both rural and urban, there is widespread segregation of the sexes; in the days of nearly universal female illiteracy (up to 1900), there was almost no possibility for a high-caste marriageable girl to meet males who might be potential sexual partners. Once girls began going to school, that possibility arose, and some parents still are afraid to send their teen-age daughters on to middle school or high school, where they might meet male students, teachers, or passers-by. A small scandal erupted in one provincial town in south India, where I lived in the 1970s, when the girls attending an all-girls' high school at a local Catholic convent were discovered writing love letters to the driver of the bus they rode to and from school.

In the traditional situation, where women of higher caste were carefully secluded and guarded from lower-caste men, women of lower caste who had to leave their homes to do their work were often considered to be fair game for upper-caste men. This sexual expression of the power of high caste over low operated even in the non-British reaches of the caste system and continues to operate today in village India, where the vast majority of the population still lives.

In one village in northern India, where I lived in the mid-1950s and to which I returned in 1984, the dominant caste is called Rajput (literally, "sons of kings"). Rajputs control most land and its cultivation, and hence the distribution of food. The other village castes consist of various kinds of artisans or service specialists—

A new and exciting American masterpiece in the rich tradition of classic bronze

"Fighting Stallions"

by Anthony Jones

A brilliant original sculpture by the 1984 Sculptor of the Year.

- *Limited Edition of only 9,500 individually serially numbered sculptures.*
- *Hand-finished and hand-rubbed to the lustrous patina of classic bronze.*
- *Hallmarked, signed by the sculptor and accompanied by a Certificate of Registration.*

Actual Size of Sculpture 10½" Across

In the rich history of bronze sculpture, few have captured wildlife with the intense drama and stunning naturalism of Anthony Jones. The powerful works of this gifted American sculptor are collected by many of the world's greatest museums. In 1984, Anthony Jones earned even further recognition when named "Sculptor of the Year."

And now, for the first time ever, the New England Collectors Society, a subsidiary of Reed & Barton Silversmiths, is honored to invite you to acquire an important, new, original work of art by Anthony Jones, "Fighting Stallions." Issued in a Limited Edition of only 9,500 individually serially numbered sculptures, "Fighting Stallions" is a masterfully sculpted work of exceptional realism.

Two sleek and powerfully muscled stallions are brilliantly captured in a dramatic struggle for dominance. The incredible intensity of the moment is portrayed in rich, lifelike detail — and with rare beauty. It is an extraordinary work of art which will be treasured in your family for generations.

Hallmarked, serially numbered, registered and signed by the artist, each "Fighting Stallions" will be individually created of cold-cast bronze, the sculptor's blend of powdered bronze and resins which holds even finer detail than hot-casting. Each sculpture will then be meticulously hand-finished and hand-rubbed to the lustrous patina of classic bronze. A Certificate of Registration will accompany each sculpture.

To acquire this magnificent original work of art by Anthony Jones, simply return the reservation application.

The New England Collectors Society is a subsidiary of Reed & Barton Silversmiths, makers of fine products since 1824.

weavers, carpenters, shoemakers, laundrymen, sweepers, barbers, and water carriers. The heart of the village caste system as an economic system is a series of exchanges between the dominant caste and the specialist castes.

Under British rule, and still in the 1950s, the Rajputs depended heavily on the Chamar caste to till their fields. The Chamars acted as agricultural servants, receiving pay in return. (Since the 1950s, land shortages due to population pressure and increased mechanization of farming have made this arrangement less common.) Because they are historically identified as leather workers, Chamars are among the lowest castes in the hierarchy—untouchables, as they are known in English. In Indian languages such groups are referred to by a term that usually translates as "unclean" (Hindus regard working with leather as unclean).

The village is considered to belong to the Rajput caste, and Rajputs do own most of the cultivable land. Members of other castes, even though their ancestors may have settled in the village hundreds of years ago, are considered to be guests, there at the invitation of the Rajputs and remaining there by their grace. Rajputs have resorted to violence to insure their village rule, and that violence is sometimes expressed in rape and sexual exploitation of lower-caste women.

Ram, a Chamar elder whom I interviewed in the mid-1950s, told me of various such incidents. He described an event that probably took place in the 1920s:

> The Rajputs try to laugh down honest people. There was a young potter bride. Rajput men tried to force her into adultery, but she did not agree. She tried to avoid that path. They offered her money, ten or fifteen rupees. Even then, she did not agree. Three Rajputs got her by force. She had just had her final marriage rite, and she was very beautiful. When she did not agree, they trapped her in a house by force and raped her there. When they finished their bad work, they put the rupees on her body and slapped them, and said, "Don't you need this money?"

Ram reported that a Rajput man might push an untouchable woman's husband out of his own house, the Rajput raping the wife with full knowledge of the helpless husband.

Early in the twentieth century, lower-caste villagers did own small parcels of land, but it became more difficult for them to retain ownership as population pressure increased. Ram told me of a Chamar who owned about twenty-five acres. In the early 1940s he quarreled with some Rajputs whose land he had to cross to reach his own. The upshot was that these Rajputs refused to let him cross their land. They also tapped so much water from the common irrigation canal that his land was left dry. They let their cattle go into his fields, and they cut his partly grown sugar cane. A group of them even attacked the Chamar and some of his relatives. The pressure mounted so that the Chamar eventually sold his land. Still, there was resentment on the part of some of his Rajput enemies because he had not sold some of the land to them. Soon thereafter (by now about ten years after the initial quarrel), the Chamar's grandson brought his bride home from their final wedding rite. As they came from the railroad station in the nearby town, they met two enemy Rajputs, coming from the sugar mill. The Rajputs beat the husband senseless, and they took the bride into the sugar cane fields and raped her.

Ram, who spoke of these incidents, believed that in times gone by, the Rajputs had been protectors, rather than exploiters, of the lower castes:

> The Rajputs used to be good. They would see our mothers and daughters with good hearts. Now they don't. Therefore, they are less powerful. They saw the poor and gave things. Now they don't. They were more powerful then. It used to be that if anyone who was more powerful than we troubled us, the Rajputs used to protect us. They would face the powerful ones troubling us. Now, they themselves suppress us.

The loss of noblesse oblige that Ram perceived may reflect a change in Rajput attitudes that occurred when their dominant position was challenged by Gandhian, Congress Party, and other reformers who, from the 1920s to 1950s, worked to elevate the lot of untouchables. Ram was suggesting the reverse interpretation, however. A traditional Hindu idea is that when people do not follow their dharma, or religiously given duty—which includes the protection of those dependent upon them—their physical and social conditions are greatly weakened.

Not all intercaste sexual relations in the village were forced upon the lower-caste women, of course. Some women established long-standing affairs with higher-caste men. A relationship could begin when a Chamar women was cutting fodder or cane in the fields or as she went about selling bundles of fodder to the higher-caste men at their cattlesheds. Such an eventuality was strongly disapproved of by the members of the woman's family. Ram told of a Chamar woman who used to go to her Rajput lover. When her husband's younger brother went to the Rajput's cattle yard to take her back, he was beaten by four or five of the men in the Rajput household. He finally had to flee the village.

Then there was the case of an untouchable sweeper woman who began a love affair with a Rajput back in the 1930s. The young couple became notorious when their relationship was exposed by an older sweeper woman who discovered them making love in a cattleshed. The two, their faces covered with lampblack, were paraded about the village on donkeys as a rite of humiliation. Then both were driven out of the village. But eventually they returned and were accepted back by their respective caste communities. When I was there in the 1950s, the woman was a widow in her forties. Gossip had it that the affair continued and that whenever the woman was involved in a dispute with other sweepers, she would call on the protection of her Rajput lover.

While probably neither the British nor Indians were consistently strict about illicit intracaste connections, both generally felt dishonored when sexual relations crossed caste lines. But the morality of the caste system is only partially portrayed in *A Passage to India* and *The Jewel in the Crown,* which ignore the sexual exploitation of lower-caste women. The bitter irony of the caste system is caught in a remark that Ram made to me: "The Rajputs are ever ready to have contact with our women, but with us men, they don't even let us touch their clothes."

The motives for exploiting lower-caste women were not the same for the Rajputs and the British, however. Among the Rajputs, women of lower castes were substitutes for prostitutes of whom there were none in the village. And rape of these women was an act of dominance indicating that the lower castes were defeated communities, with no right even to the belief in the chastity of their women. The British, instead, endured their enlisted men's sexual exploits with Indian prostitutes because they preferred to keep these men single. That way the soldiers would be unencumbered with family responsibilities as they risked their lives in battle; in addition, the military service budget would be relieved of the costs of the families' upkeep. Marriage between the British and Indians was specifically discouraged because, as Ballhatchet concludes, "rulers should be aloof from the people and so trusted as beyond corruption and feared as remote from the common ways of common men."

Pauline Kolenda is a professor of anthropology at the University of Houston, University Park.

EMBERS'
EW YORK
EEKEND

NEW YORK, NATURALLY!

(Designed exclusively for Members of the American Museum of Natural History)

Whether your first love is art or archaeology, elegance or evolution, Tiffany or Tyrannosaurus rex, the stars of the heavens or the stars of Broadway, you'll find it in our Members' New York Weekend. For three exciting days and two wonderful nights, a great city and a great Museum will be all yours.

- **Two nights in one of New York's finest hotels:** Stay at The Waldorf Astoria, The Parker Meridien, or The Plaza. Minutes away from New York's famed theater, shopping, and eating districts and only a short ride away from the Museum itself.
- **Two complimentary meals:** Enjoy a full breakfast at your hotel and a leisurely lunch in the Museum's charming greenhouse-style restaurant.
- **The Official Guide and a Highlights Tour:** As soon as you make your reservations, we will send you the Museum's Official Guide to introduce you to our fabulous treasures. And when you arrive at the Museum, take a Highlights Tour, which provides fascinating insights into the Museum's most popular halls. Or savor the Museum at your own pace. Journey through halls filled with gems, dinosaurs, myriad life forms, and peoples from all over the world. The Star of India sapphire, wolves hunting in the night, ancient totems of the Northwest Coast, and Mayan sculptures are just a few of the Museum's varied wonders. At the end of your visit, relax in our private Members' Lounge or take advantage of your Members' discounts at Museum gift shops.
- **Special Exhibitions:** The Museum presents an exciting schedule of special exhibitions throughout the year. Through July: *Maya: Treasures of An Ancient Civilization* and *John James Audubon: Science into Art.*
- **Free Planetarium and Naturemax Tickets:** Journey through the heavens in the Planetarium's famed sky theater and enjoy the film experience of a lifetime at Naturemax, with its movie screen sixty feet wide and over four stories high.
- **Personalized Service:** The Members' Service Desk will help customize your weekend to suit your needs and tastes. They'll be glad to arrange theater or concert tickets, reservations at New York's top restaurants, a carriage ride through Central Park, or tours of the town.
- **Discount air fares:** Special rates are available on American Airlines, the official airline of the Members' New York Weekend.

Tour Program Price: $92.50 per person, per night. Tax included. Based on two nights double occupancy. Rates also available for families and individuals.

Call or write today for reservations, brochures and more information.

Cranberry Glades, West Virginia

by Robert H. Mohlenbrock

Some of West Virginia's Monongahela Forest is so dense that summer sunlight doesn't reach the forest floor. At higher elevations, where the climate is cool, rainfall abundant, and fog common, the tree cover is provided by red spruces, yellow birches, and balsam firs. Sugar maples, beeches, basswoods, and white pines dominate the mountain ravines. There are even a few virgin stands of red spruce, where trees three to four hundred years old have been spared from lumbering. With so much unbroken forest, one vast opening, where only the occasional tree rises above a sea of low-growing vegetation, provides a startling inconsistency. This is Cranberry Glades, a bowl-shaped, boggy area at the foot of three mountains—Cranberry, Black, and Kennison.

The basin containing Cranberry Glades is about three miles long and up to one mile wide and about 3,400 feet above sea level. Penetrating the heart of the glade are Cranberry River and its tributaries, Charles Creek and Yew Creek. Cranberry River, which originates from springs halfway up Cranberry Mountain, never spreads more than twelve feet across. Four treeless bogs, ranging in size from eight to sixty acres, are scattered through the basin. The rest of Cranberry Glades consists of dense thickets of shrubs or bog forests.

The four bogs have a layer of peat that may reach a depth of eleven feet. Peat (dead sphagnum moss that has sunk beneath a mat of living sedges and heaths) builds up where there is insufficient oxygen to promote the complete decay of vegetable matter into soil. Beneath the peat in Cranberry Glades is usually a layer of algal ooze that may be another two feet thick. This is a dark, jellylike material, the decomposed remains of algae that lived tens of thousands of years ago. During spring, the water table may come within an inch of the peaty surface, while in autumn, it drops nearly one foot.

Bogs often form in lakes where poor drainage allows organic detritus to accumulate, principally from sphagnum moss that grows along the water's edge. Early explorers in the glades thought that the wet basin was once a natural mountain lake, probably one that resulted when a landslide created a dam. The evidence, however, casts doubt on their theory. Since the downstream end of the glade is nearly fifty feet lower than the upper end, and is five hundred feet wide, the area could not have been flooded unless a landslide built a dam fifty feet high and five hundred feet wide. There are no remnants of any such dam. In addition, the deepest peat is at the upper end of the basin. If lake waters once covered the entire area, the thickest layers of peat would be at the lower end, where the water would have been deepest. Finally, some parts of the glade do not have peat deposits, an unlikely occurrence if the bog had developed in a lake.

H.D. Darlington, a biologist who studied the Cranberry Glades extensively, noted that the peat varied in thickness throughout the glade and was absent under the streams. If the basin had been covered by a lake, there would be peat under the streams today. Darlington theorized that sediments formed levees along the streams; whenever the streams then overflowed, water was trapped in low-lying areas outside the stream banks. Thick accumulations of peat developed in these basins. Darlington also proposed that some peat may have been deposited in stream beds abandoned when drainage patterns shifted. Even in recent times, there is evidence that the Cranberry River has been straightening its course, eliminating some of its old meanderings.

Peat is so acidic that most of the plants that flourish in the adjacent mountain forests are unable to grow in the bogs. Plant life in the open bogs is dominated by two species of cranberries, which are trailing evergreens whose rosy summer flowers develop into tart red cranberries by September. (The species producing the larger berries is the same as that harvested commercially.) Both of these bog-inhabiting plants of the heath family are more common in the northern states and Canada. Another heath that grows in the open bogs is the bog rosemary; its presence marks the southernmost place in the world where it grows naturally. Fungi living on and in the roots of the heaths and other bog-inhabiting plants help them survive by making available nutrients that, in acidic conditions, are not generally found in usable form. Biologists call this mutually beneficial relationship *mycorrhiza.*

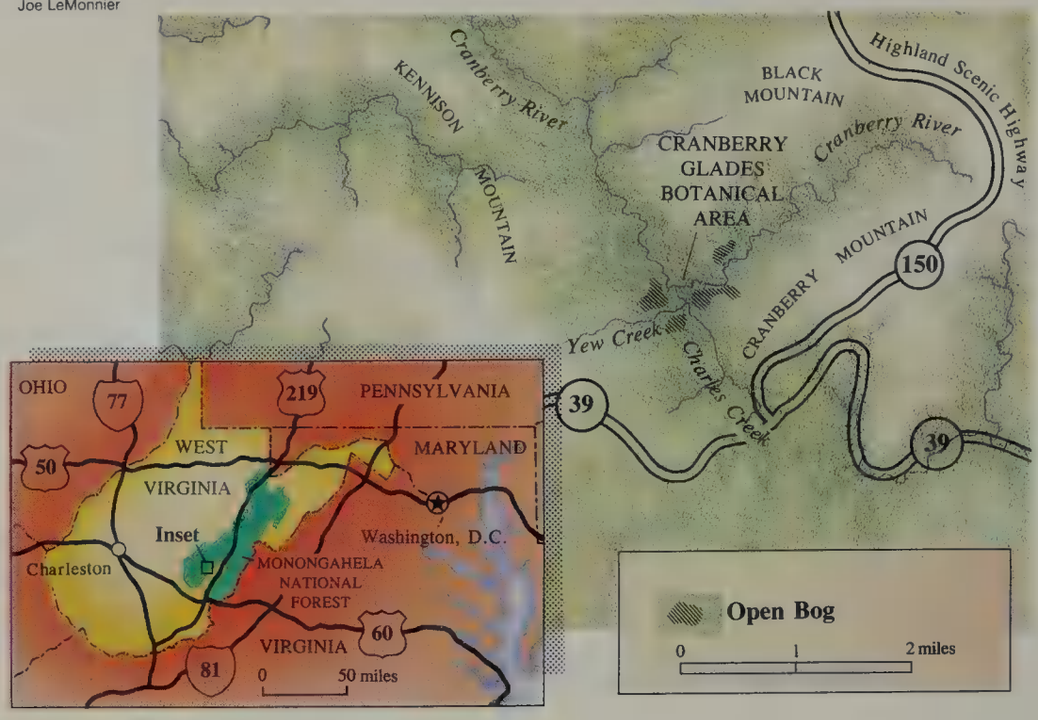
During spring and summer, the open bogs are green, punctuated by occasional flashes of yellow from the showy flowers of the swamp candle and pink from two kinds of wild orchids. In autumn, however, white dominates the vegetation, appearing like a blanket of light snow. Flowers of the white-top aster blend with the smaller milk-white flower clusters of the beaked rush, and the seed heads of cotton grass are entangled in masses of hairs.

Nonflowering plants, such as mosses and lichens, hug the surface of the peat. The mosses are so abundant in places that they form small mounds known as hummocks. The mosses and lichens are in constant competition. During extended periods of rain, the fast-growing gray lichens spread over the green mosses, forming an intricate parquet. But in dry weather, the lichens crumble into powder, and the mosses surge over their desiccated tissues.

Surrounding part of the open bogs are almost four hundred acres of a nearly impenetrable thicket of slender-branched shrubs. There are twelve different kinds of shrubs, including the swamp rose and the speckled alder, whose stems are covered by conspicuous white-blotched pores that assist the plant in the exchange of gases. In summer, great masses of white woolly aphids cover the alders, giving the thickets a stark and eerie appearance. Beneath the shrubs grow a diversity of wildflowers that provide a year-round display, from the

David Muench

Joe LeMonnier



skunk cabbage, which forms its fetid flowers while snow still covers the ground in February, to the aster, turtlehead, and monk's-hood, which flower in the fall.

Sometimes lying between the wet alder thickets and the rich hardwood forests of the surrounding mountains is a bog forest where red spruce, Canadian hemlock, yellow birch, and black ash grow above a soggy forest floor covered by wood sorrel and mosses. From the branches of the bog forest trees hang long festoons of the *Usnea* lichen, reminiscent of the totally unrelated Spanish moss.

The encroachment of woody plants from the surrounding shrub and forest communities is a major threat to the open bogs. Shrubby Saint Johnswort is particularly aggressive, but chokeberry and winterberry are invading at a rapid rate. Most trees cannot establish themselves in the bogs because they can't find firm anchorage, but a few have reached maturity where conditions are favorable. Some West Virginia botanists speculate that in just a few hundred years woody plants will transform the entire basin into a bog forest.

Until a few years ago, Cranberry Glades was several miles from the nearest public road and virtually inaccessible, except to the ardent hiker. Today, however, the Highland Scenic Highway passes near the Glades, a modern visitors' center has been erected nearby, and a short boardwalk has been provided. The boardwalk passes through a bog forest and an alder thicket before cutting across the corners of two of the open bogs. It not only protects the sensitive ecosystem from indiscriminate trampling but also keeps visitors from miring-in up to their waists.

David Muench

Most trees cannot grow in Cranberry Glades' boggy soil, but woody plants may eventually transform the entire basin into a bog forest.

Relive the "Wild West Adventure"...

The Historic Old West Wall Treasury

of genuine U.S. Gov't coins, stamps and Frederic Remington prints.

Four rarely seen and out-of-issue collections of U.S. Gov't coins and stamps up to 76 years old — featuring authentic turn of the century reprints of the fabled Old West master painter — Frederic Remington. Mounted on antiqued panels, and framed in solid wood, ready for display.

Bring a wall setting to life with dramatic American history! Vivid historic prints and authentic old coins and stamps recapture the romance of the Frontier. A beautiful addition to any room — a thoughtful gift for special friends.

The Complete Historic Old West "Wall Treasury" makes a perfect gift for friends, family, and collectors.

The American Indian

- Features a reprint of Remington's "The Mystery of Thunder" painting published by Harper's Monthly in 1897.
- Includes eight genuine U.S. Gov't Indian Head pennies and nickels up to 76 years old.
- Displays out-of-issue U.S. mint postage stamps dating as far back as 1948.
- Antiqued background panel reproduced from hand-carved leather.
- Solid wood frame measures 10½" × 12½": rich walnut finish, gold tone inner piping, unbreakable transparent cover, built-in hanger for instant display.

For Fast Delivery, Call Toll-Free
1-800-451-4463
7 days a week including Sundays!

The Forty Niners

Features a reprint of Remington's famous 1887 painting "Panning for Gold". Includes six genuine U.S. Gov't Liberty Head "V" nickels dating from 1883-1913, three out-of-issue U.S. postage stamps dating back to 1948, plus a capsule of genuine silver granules.

The Trailblazers

Features Remington's "Bell Mare" — originally published by Collier's Magazine in 1904. Includes U.S. Lincoln "Wheatback" pennies (even scarce 1943 steel shell-case cents), an obsolete silver Mercury dime, and four U.S. stamps up to 37 years old.

The Pioneers

Features the Remington engraving "Water!" which appeared in a 1890 issue of Century Magazine. Includes ten genuine U.S. Gov't Indian Head and Buffalo nickels minted from 1913-1938, and five U.S. postage stamps dating back to 1946.

An adult rusty crayfish
All photographs by Doug Stamm/PROPHOTO

Lake-Bottom Tyrant

Aggressive and prolific, the rusty crayfish has clawed its way to the top of the food chain in northern Wisconsin lakes

by David M. Lodge, Annamarie L. Beckel, and John J. Magnuson

At their summer camp on Long Lake, Wisconsin, the Girl Scouts had to retreat from the water; they could no longer swim without being constantly pinched by crayfish. That was in the mid-1960s. While certain crayfish had always lived in the lake, local residents recognized the current nuisance as a newcomer. Plant life was also under attack. Dense beds of aquatic vegetation, such as the rich patches of musky weed that had always attracted fish and fishermen, simply disappeared. The crayfish ate their way northward from the far end of the lake, leaving a few tough-stemmed waterlilies and an otherwise barren lake bed in their wake. The culprit was *Orconectes rusticus,* the rusty crayfish.

A few years later and 120 miles to the northeast, property owners and fishermen witnessed the decline of Lake Metonga, known throughout Wisconsin as a hot spot for walleye and perch. The lake teemed with crayfish, and vegetation dwindled every year. By the late 1970s, walleye no longer successfully reproduced. Soon all the weed beds in the lake were gone. By 1983, the Wisconsin Department of Natural Resources (WDNR) had spent $17,000 to stock the lake with walleye and lend support to a citizens' group that was trying to bring back aquatic plants. The rusty crayfish had struck again.

The rusty is one of three, originally southern species of crayfish that are relatively recent immigrants to Wisconsin lakes. Fifty years ago, the fantail (*O. virilis*) was the only species present, probably having reached this region through natural migration up tributaries of the Mississippi. Then the blue crayfish (*O. propinquus*) appeared and flourished. But only within the last thirty years has the rusty crayfish left its southern home and invaded the lakes of northern Wisconsin.

The rusty probably got a free ride from Illinois and Ohio fishermen vacationing in the Wisconsin lake district. Live crayfish were a favorite bait until their use was outlawed in 1983. Fishermen hardly foresaw ecological disruption when they dumped their extra bait, including rusties, into the lake at the end of the day. When commercial trappers, who had long sought and sold "crabs" within the state for bait and human consumption, discovered the prolific rusty crayfish, they gave the migrant a helping hand, broadcasting the rusty into some isolated lakes the crustacean might not otherwise have easily reached. Such practices accelerated the rusties' advance, and the crayfish proceeded to thrive beyond anyone's expectations.

While its predecessors, the fantail and blue, appear to be benign members of the ecological community, the rusty crayfish has become notorious in northern Wisconsin, thriving at the expense of native crayfish, plants, and fish. What physical and biological constraints prevent the fantail and blue from dominating their surroundings, and what traits enable the rusty to establish a lake-bottom dynasty?

A team of biologists from the University of Wisconsin at Madison Center for Limnology has undertaken a long-term ecological study of lakes subject to rusty crayfish depredation. As part of that team, we have used the lakes as a natural laboratory for the past ten years to investigate the habits and interactions of the fantail, blue, and rusty crayfish.

These three kinds of crayfish are similar in appearance, behavior, and habitat preference. Northern Wisconsin lake habitat is like that of the streams occupied by *Orconectes* species farther south. The well-oxygenated water has adequate calcium, enabling crayfish to maintain their calcium carbonate exoskeleton. All three species favor shallow areas of fist-sized rocks, called cobble, where each individual selects and defends a lake-bed shelter. Typically, a crayfish excavates a cave under the edge of a rock or sunken log, leaving a small mound of sand and gravel at the opening. The crayfish then backs into its home, leaving only its eyes and massive pincers (or chelae) visible, and warily watches its lacustrine world. Most crayfish remain in hiding during the day and emerge to forage only at night.

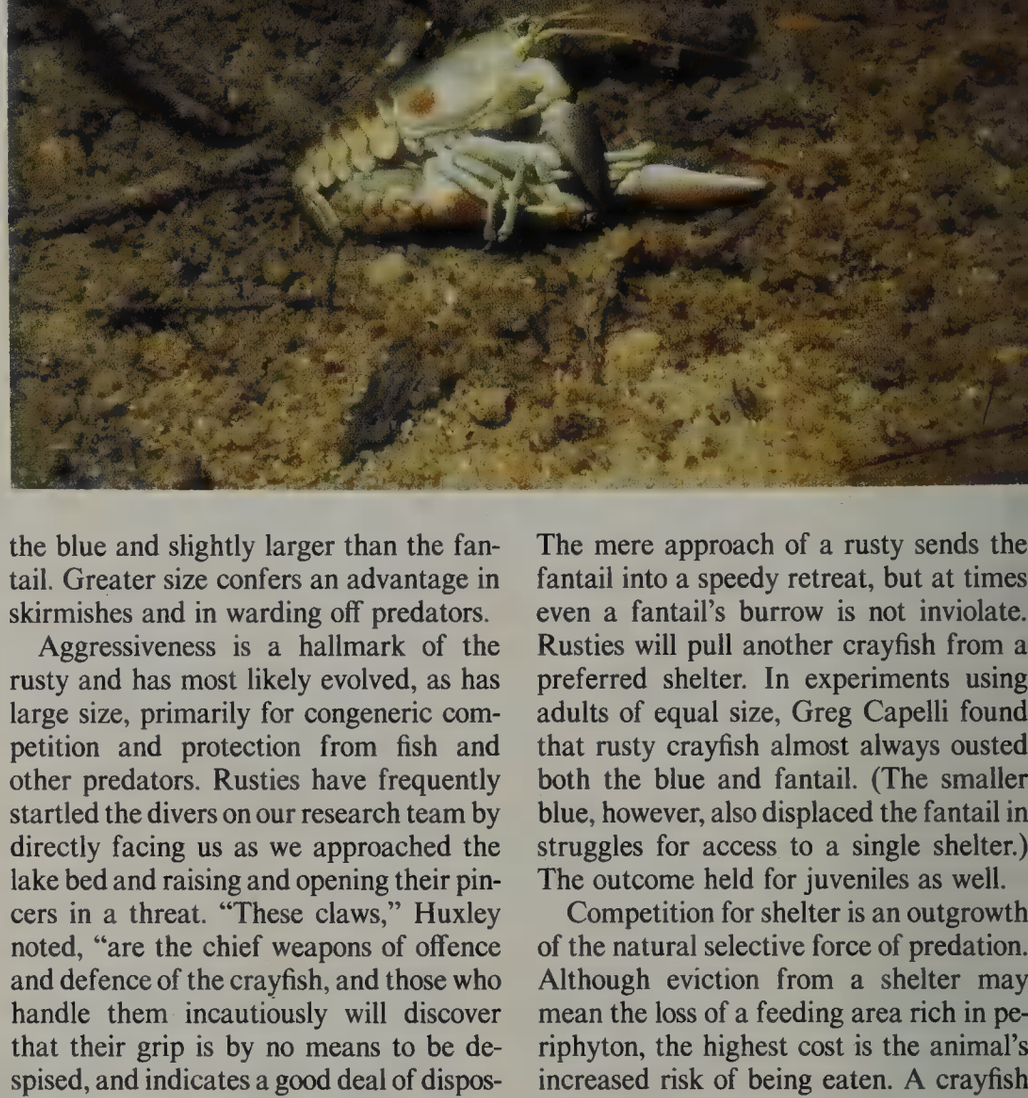
In an 1880 monograph, Thomas H. Huxley described crayfish as opportunistic and enthusiastic feeders:

> Larvae of insects, water-snails, tadpoles, or frogs, which come within reach, are suddenly seized and devoured, and it is averred that the water-rat is liable to the same fate. Passing too near the fatal den, possibly in search of a stray crayfish, whose flavour he highly appreciates, the vole is himself seized and held till he is suffocated, when his captor easily reverses the conditions of the anticipated meal.

Huxley may have overstated the case in regard to live small mammals on the crustacean's menu; but crayfish do vigorously attack vulnerable animals. Large prey, typically fish, are usually sick or dying when attacked. Stories abound of rusty crayfish reducing fish to bones in an hour. Crayfish use their chelae and the small pincers on their first two pairs of walking legs to reduce large pieces of food to a whirling cloud of small particles.

Yet crayfish are omnivores. Although they seek out high-protein animal food, such as fish eggs, carrion, and insect lar-

Crayfish in Wisconsin lakes may mate at any time from late summer to early spring. The female stores sperm in an abdominal pocket until she is ready to lay up to 200 eggs in April or May. The offspring of rusty crayfish typically hatch earlier and grow faster than blue and fantail young. Below: Adopting a mating posture atop a female, a male rusty crayfish holds down her powerful pincers with his own.



vae, much of their diet consists of generally more abundant but less nutritious plant food. At night, they scrape periphyton, or "scum flora," a complex green or brown film of organic detritus, bacteria, and algae, from the surface of rocks. As Huxley points out, "Few things in the way of food are amiss to the crayfish; living or dead, fresh or carrion, animal or vegetable, it is all one."

These three *Orconectes* species have a similar life cycle. Like other crustaceans, crayfish periodically molt, shedding and re-forming their hard exoskeleton to allow for growth. Adult male *Orconectes* molt at least twice a year: into nonbreeding form in early summer and reproductive form in late summer. Mating may take place at any time from late summer through early spring, but the female stores sperm in a pocket in her abdomen until April or May. She then lays as many as 200 eggs and fertilizes them externally. They remain attached to her abdomen until they hatch into bulbous-headed, thin-tailed pink juveniles. The young remain close to the female for about two weeks, molting several times and gradually taking on the appearance of miniature adults.

In 1980, Greg Capelli, of the University of Wisconsin, surveyed eight area lakes that in 1975 had low populations of rusty crayfish and relatively high populations of fantails, blues, or both. During the five-year interval, the number of rusty crayfish had increased in seven of the eight lakes, and fantails and blues had declined proportionally. In lakes subject to a population explosion of rusties, fantails and blue crayfish were virtually nonexistent.

From the start, the rusty crayfish has an advantage over its other *Orconectes* lake mates. Its eggs hatch earlier in the spring than blue and fantail eggs and its young grow faster. During dives under the ice in April, Jim Lorman, of the University of Wisconsin, observed many rusties already carrying eggs. Quicker growth means that rusty offspring are bigger than immature blues and fantails of the same age. Rusty males have large chelae, and at maximum adult proportions (four inches from head to tail, plus about half that length in chelae) the rusty is considerably larger than the blue and slightly larger than the fantail. Greater size confers an advantage in skirmishes and in warding off predators.

Aggressiveness is a hallmark of the rusty and has most likely evolved, as has large size, primarily for congeneric competition and protection from fish and other predators. Rusties have frequently startled the divers on our research team by directly facing us as we approached the lake bed and raising and opening their pincers in a threat. "These claws," Huxley noted, "are the chief weapons of offence and defence of the crayfish, and those who handle them incautiously will discover that their grip is by no means to be despised, and indicates a good deal of disposable energy." Like the bathers at Long Lake, we have been pinched, with blood drawn, by defiant rusties standing their ground and resisting capture.

Trout Lake, site of a small but expanding rusty crayfish population and the largest of the lakes in the Northern Lakes Long-Term Ecological Research Project, is now the focus of a time-course study. Experimental results from our laboratory at the lake help explain how behavior, as well as physical attributes, enables the rusty to literally dislodge competitors. The bullying rusty is more than a match for the relatively docile, easily handled fantail. The mere approach of a rusty sends the fantail into a speedy retreat, but at times even a fantail's burrow is not inviolate. Rusties will pull another crayfish from a preferred shelter. In experiments using adults of equal size, Greg Capelli found that rusty crayfish almost always ousted both the blue and fantail. (The smaller blue, however, also displaced the fantail in struggles for access to a single shelter.) The outcome held for juveniles as well.

Competition for shelter is an outgrowth of the natural selective force of predation. Although eviction from a shelter may mean the loss of a feeding area rich in periphyton, the highest cost is the animal's increased risk of being eaten. A crayfish exposed on the lake bottom is much more likely to become a meal than one hidden under a rock, and during molting and one to two days afterward, the "soft shell" crayfish without a shelter is completely defenseless. Although many birds and mammals eat crayfish, fish are the most common predators. As a crayfish grows larger, little fish, other crayfish, and dragonfly larvae no longer pose a threat. Only large fish, particularly mature smallmouth bass, hunt adult crayfish. By dominating available shelters, the rusty more easily escapes predation. Fish predators also determine to a degree the behavior of

A rusty crayfish feeds at night on a stand of long-stemmed water plants. In some Wisconsin lakes, grazing by rusties has nearly eliminated vegetation and plant-dependent invertebrates, such as snails.

heir smaller crayfish prey and may hereby indirectly affect the growth of periphyton and water plants. In studies by ecologist Roy Stein, now of Ohio State University, smaller crayfish, such as the adult blue, responded to the presence of fish predators by remaining in shelters and curtailing feeding. Under the pressure of predation, the fantail, blue, and to a lesser extent, the rusty crayfish are less active and eat fewer plants. Sizable crayfish, however, especially rusty males, can often feed with impunity on open, sandy lake bottoms, even in daylight. Few fish are large enough to tackle the biggest rusties; those that try are often easily dissuaded by the defensive display of pincers. Like Huxley, we on the study team have seen the tables turned on would-be predators; if a smallmouth bass fails to launch its attack from the rear, the bass may end up trying to shake off a persistent crayfish that has clamped onto its lips.

The rusty crayfish, then, can evade capture and drive competitors into the mouths of predatory fish by expropriating available shelters. But a more subtle mechanism of species replacement may also be at work. In some lakes, many crayfish show characteristics intermediate between the rusty and the blue crayfish. Whether these individuals are fertile and whether they rank high in competitive ability remain to be seen, but their existence is strong evidence for ongoing hybridization.

Crayfish recognize members of their species and opposite sex partly through pheromones, the signal-sending chemicals also used by many insects. Male rusty crayfish more often misidentify others of their kind than do blue and fantail crayfish, a mistake that works to the rusty's advantage. Greg Capelli discovered that rusty males frequently mate with blue and fantail females. If these unions leave a sperm plug in the female's sperm storage pocket, she may be prevented from mating later with a male of her own species. Blue and fantail males, however, do not make the same mistake with rusty females, which are therefore inseminated only by rusty males. So with little damage to their own reproductive success, rusty crayfish undermine the reproduction of competing species.

Some rusty populations have attained densities of thirteen adults per square yard. Populations of the similar-sized fantail never reach such a level; those of the smaller blue, however, sometimes do. But the rusty crayfish's size gives it a total living biomass that far exceeds those of its two competitors. Larger size, longer feeding periods, and greater use of different substrate types, such as open, sandy lake beds and soft sediment bottoms, account for the rusty's more obvious effects on its plant and animal foods.

To compare the effects of fantail and rusty crayfish on large aquatic plants, or macrophytes, we enclosed separate populations (of equal number and biomass) of both species in a rich plant community on the bottom of Sparkling Lake. In the summer of 1983, we regularly counted the plants remaining within each of twelve crayfish corrals; four enclosures had populations of fantails, four had rusties, and four contained no crayfish. Both species ate macrophytes, favoring some plants over others, and both ate a similar amount of vegetation. Therefore, the heavy impact of the rusty crayfish is probably not due to rapacity, but to its decreased predation risk and increased densities.

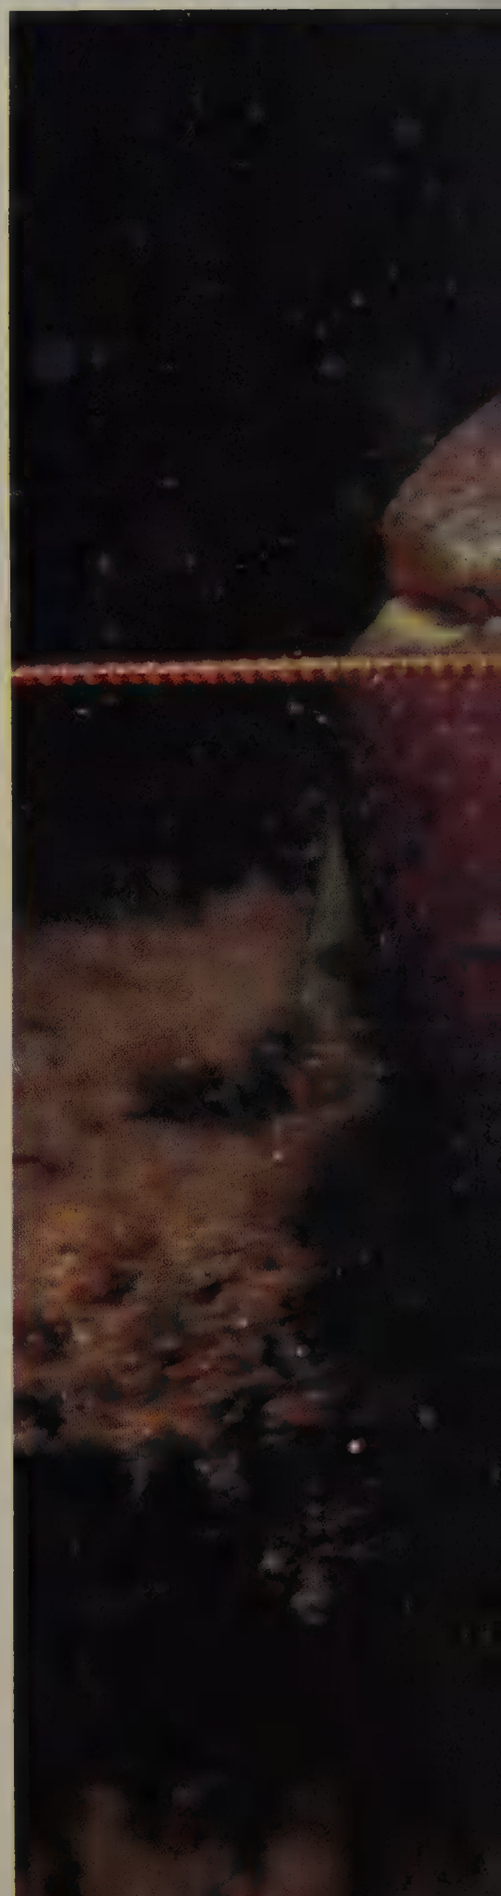
Using similar experimental methods, we compared the growth of plants in crayfish-free enclosures to that of plants subjected to grazing by ten rusty crayfish per square yard. By the end of summer, only water celery remained in the enclosure with crayfish. A dense mixture of four to five macrophyte species persisted in the nongrazed corrals. Not only did the rusty crayfish consume all plants except water celery, they also devastated the invertebrate animals that live on plants. For example, a snail commonly associated with aquatic plants was abundant in the ungrazed enclosures but absent from corrals with crayfish. Such elimination resulted largely from a combination of direct predation on snails and plant destruction.

Can even low densities of rusty crayfish make serious inroads on growth of food plants? To find out, we placed crayfish cages in an area of Trout Lake with thick stands of macrophytes. At population densities of one crayfish per square yard—a density commonly exceeded in nature—the biomass of aquatic plants was reduced by 40 percent. At a density of ten crayfish per square yard, not a single plant stem remained after twelve weeks. The data gathered allow us to make relatively precise and disturbing predictions about the alteration of ecological communities in Trout Lake as the rusty crayfish advances.

Abundance and diversity of aquatic plants and invertebrates diminish as a direct result of crayfish grazing and predation. In the past, macrophyte and periphyton primary production has fueled the secondary production of insects that fed small prey fish that in turn were eaten by large sport fish. This food chain is now being short-circuited at two levels. Crayfish now consume the plants, replacing other invertebrates as the top grazers. Snails and insects that use the remaining plant habitat are also liable to be eaten by crayfish, rather than by small fish, as they were in the past. Through the consumption of those invertebrates and of fish eggs, as well as destruction of habitat, crayfish are replacing small fish, and ultimately bass, walleye, and muskellunge as the top predators.

A horde of blue and fantail crayfish, feasting by night on a dead fish, will rapidly reduce it to bone. In lakes invaded by rusty crayfish, blue and fantail populations have declined.

by permission, University of Wisconsin Press



The shorter the food chain, as vegetarians point out, the greater its overall efficiency. But the end product of the new food chain in northern Wisconsin lakes—the rusty crayfish—is not as popular as walleye and musky. If adult rusties were more easily caught and readily consumed by these and other sport fish, such as lake trout and smallmouth bass, northern lakes might sustain more such desirable fish. As fish food, the rusty is a high-protein packet, but an evasive one, which is sheathed in a heavy, indigestible covering. Consequently, crayfish, especially adults, may not be a preferred or optimal diet for fish, but the harvesting that is a growing part of Wisconsin's economy is providing an increasingly popular item for humans.

Harvesting crayfish may provide a novel food and jobs, but it is unlikely to significantly reduce the crayfish population. Current trapping methods catch mostly males, but leave enough to fertilize the females, which in turn have less competition from males for food and shelter. The result is a continued crayfish boom. Underwater fences are expensive and at best only temporarily effective. Poisons developed to exterminate crayfish would most likely also destroy many other animals, especially zooplankton, tiny crustaceans that are an important food source for small fish. The most effective and harmless way to reduce crayfish populations would probably be to protect populations of predatory fish. Unfortunately, the very goal of crayfish control is to allow a continued take of sport fish. Perhaps the best solution is to wait for other natural interactions to rein in the rusties, and in the meantime, to encourage commercial exploitation of crayfish.

In ecological and social terms, the consequences of the rusty crayfish influx will be greater than those of the two pioneer *Orconectes* crayfish in northern Wisconsin and rusty-ridden parts of Minnesota, Michigan, and Ontario. Our perceptions may change, however, as societies both in and outside the lakes adjust to the new member of the food chain. The fantail and blue crayfish became integral parts of the ecological communities they joined, but perhaps only after local predators and parasites had learned to exploit them and local prey plants and animals had responded to the selection pressures they exerted. The natural course in the case of the rusty remains to be seen. This animal invasion has provided insights into the roles of competition, predation, and herbivory in lake communities, but it may be quite a while before humans and crayfish in northern Wisconsin come to terms. □

A rusty crayfish scrapes "scum flora," or periphyton, a complex film of organic detritus, bacteria, and algae, from the surface of a submerged log. Although crayfish are quickly attracted to carrion and live insects, most of their diet consists of less nourishing but abundant periphyton.

The World of Robert Bateman

When I think of Robert Bateman, three images come to mind. The first and dominant one is of the artist in his studio. On the easel is a large painting of a tiger. In the early afternoon the great cat had loomed dramatically from the painting; within an hour or so it had retreated behind a screen of reeds. On the artist's lap is a smaller painting of a hawk. As he talks, he works on both paintings, moving casually from one to the other—the same brush painting the same color on little sections of each, although they are totally different in subject, scale, and tone. Beside him, to his right, is a little trolley with his paints and brushes and sponges and water. As he works, he wipes his brush off on the underarm of his old sweater. He wears a visor against the studio's fluorescent lights, which are gradually taking over from the fading afternoon light coming through the large windows.

The second image is of the artist in the field. In a gentle, misty rain, Robert Bateman is stumbling up a slippery mountain creek bed. Encumbered with a camera on a tripod, a sketchbook, and an umbrella, and wearing an Irish tweed hat, a slicker, and bright yellow rain pants, he is a pleasantly bizarre figure, reminiscent of the eccentric nineteenth-century field naturalists. He looks at everything: the lush vegetation, the texture and colors of lichens on the rock, the quality of the light.

The third image is of Bateman the public figure. Genial and dapper, with only a slight aura of the studio and the out-of-doors, he is lecturing to a large audience at one of the openings of the hugely popular exhibition of his paintings that has been touring Canada and the United States for the past three years.

On occasions such as these, he is likely to tell the story of his career as an artist. He does this in an easy, self-deprecating manner, showing slides of his paintings, starting with some of his childhood works. This talk traces the various stages of his career as an artist and is also an easy lesson in how to look at a Bateman painting.

Bateman was born in 1930 and grew up in Toronto when the countryside was closer to the city than it is now and the ravines beside his family home were filled with small wildlife and migrating birds. He became obsessed with both art and nature at an early age and spent most of his youth drawing, painting, and learning about the local bird and mammal life. His paintings from these years clearly relate to his mature work: the animal subjects are not confronting or responding to a human viewer, and there is a careful and knowledgeable presentation of the surrounding habitat.

At that time, Toronto's Royal Ontario Museum was beginning its fine program for budding artists and naturalists, and all of Bateman's early training came from its accessible and able staff. By the time he was seventeen he had an excellent general knowledge of North American bird, mammal, and plant

life. This was augmented by summer jobs with wildlife research teams in Algonquin Park in northern Ontario and later, during his university and post-graduate years, on biological and geological field parties in Newfoundland, Ungava in northern Quebec, and on Hudson Bay. Travel, generally focused on wildlife biology, became important to him. His first journeys took him around North America, then to Europe, and ultimately, when he was in his late twenties, around the world on a year-long journey in a Land-Rover.

By the late 1970s, Bateman was recognized as one of the world's outstanding artists in the field of animal art. Since then, his paintings have become enormously popular and he has achieved a degree of public celebrity. He is an insatiably curious naturalist, a willing teacher, and a dedicated conservationist, but he remains an artist first and foremost.

Ramsay Derry

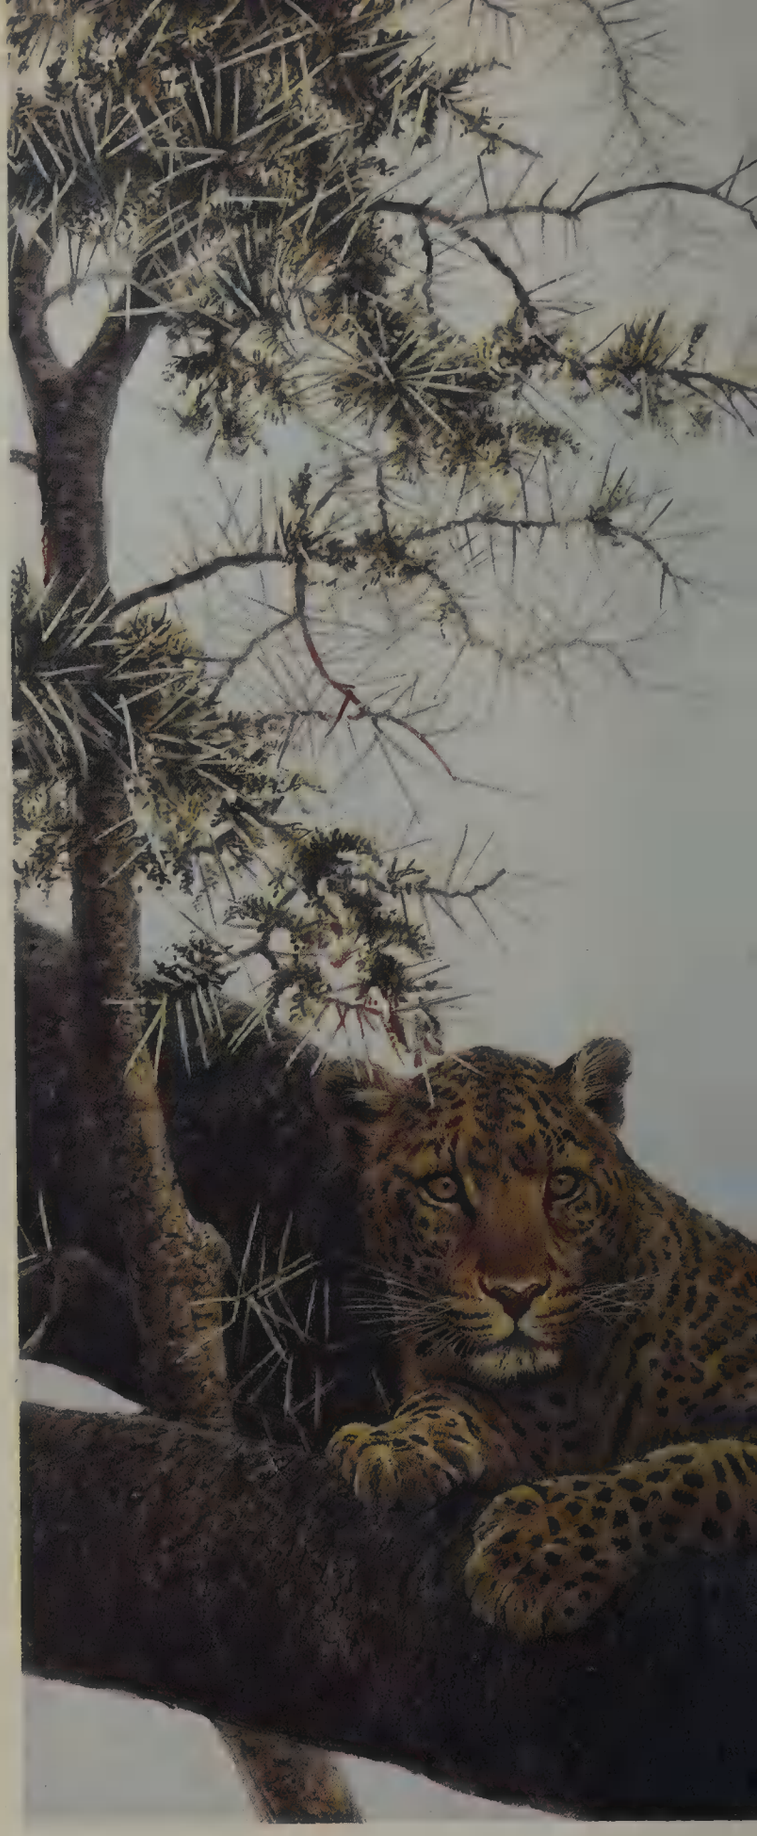
From the forthcoming book *The World of Robert Bateman*, text by Ramsay Derry. Text and compilation copyright ©1985 by Madison Press Books. Artwork copyright ©1985 by Boshkung, Inc. To be published by Random House, Inc.

"I can't conceive of anything being more varied and rich and handsome than the planet Earth. And its crowning beauty is the natural world. Whether it's here in Ontario or in the Antarctic or in Africa, I want to soak it up, to understand it as well as I can, and to absorb it. And then I'd like to put it together and express it in my paintings. This is the way I want to dedicate my work."

Robert Bateman, 1981

ELEPHANTS

"When I saw this gnarled old stump it seemed to me a whole world in itself. The insect tunnels and the wear and tear of weather and age fascinated me and became the driving force for this painting. The shape and texture of the stump and its curving dead root suggested elephants as a related subject. Even at a distance, elephants are impressive animals, but they usually prefer to keep some kind of cover between you and them, particularly if they've got young ones with them. I put them behind a screen of scruffy, chewed-up trees and they are also veiled by the dust that they normally stir up when disturbed."



LEOPARDS

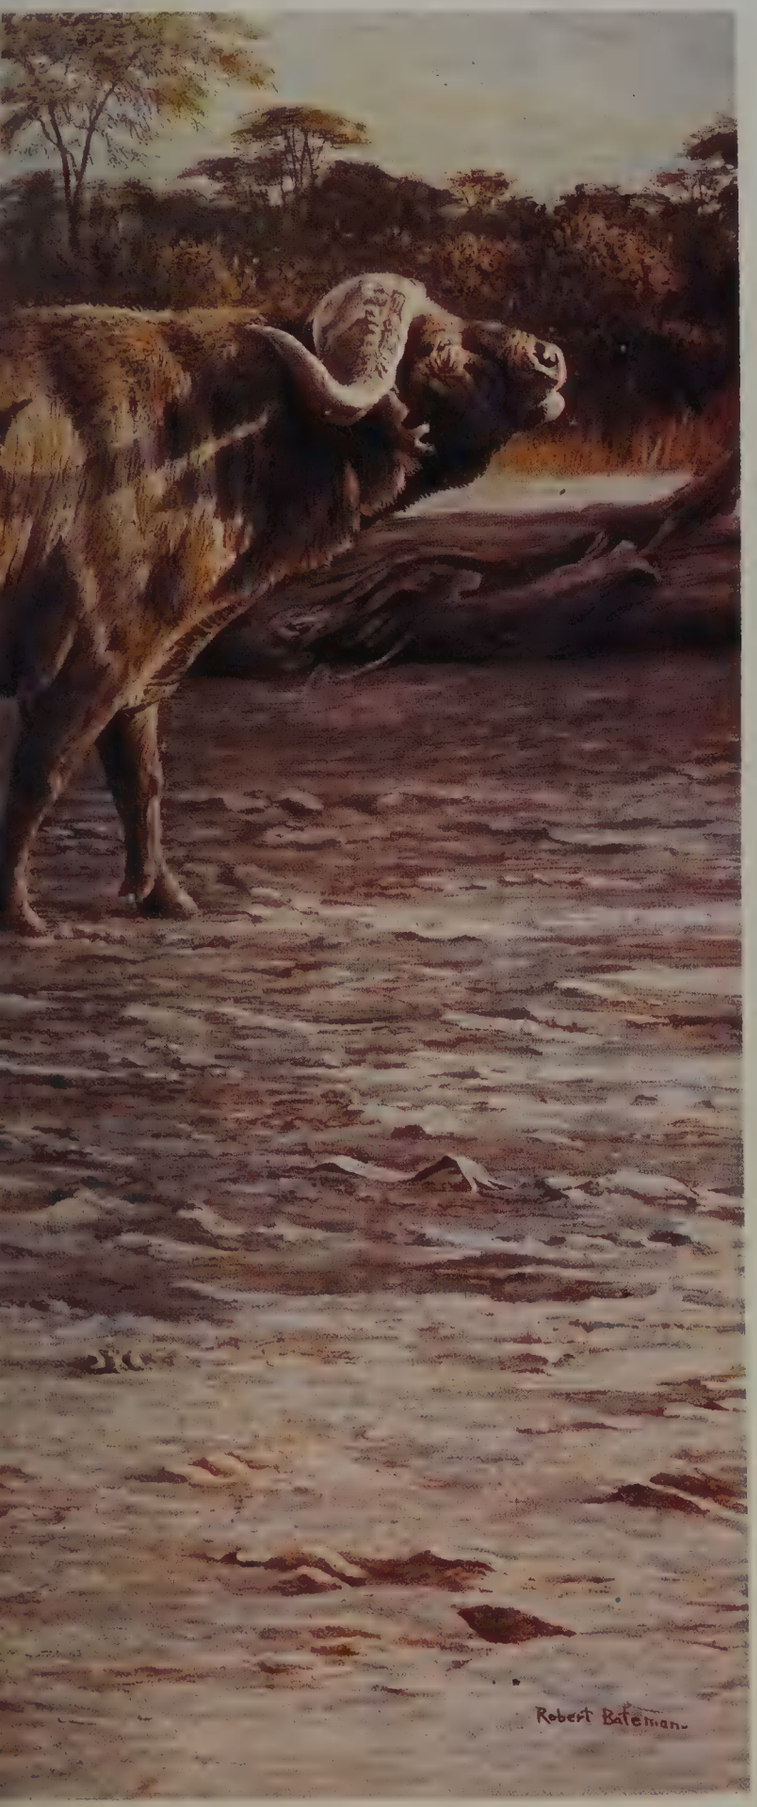
"On safari in Tanzania, I spent a lot of time peering up into trees looking for leopards—without success. They are comparatively hard animals to see in the wild—much more difficult, for instance, than lions or cheetahs—and I had never had a really good view of one. Finally, at the end of a long day, I was told where one had been sighted, and hurried to the spot. The leopard had climbed up into a tree with a fresh kill, a Thomson gazelle.

The leopard was still too tired to eat, for the gazelle that he had just hunted down and dragged up into the tree must have weighed almost as much as he did. He just lay there watching me, with only a slight sense of nervousness and tension.

When I came to paint the picture, I didn't portray any gore, but you can see the stickiness around the throat of the gazelle where the leopard has strangled it. Even in death, the Thomson gazelle seemed a delicate and lovely creature. As I worked on the painting, the drooping shape and broken limbs of the gazelle interested me, and I echoed them in the drooping, broken branch of the tree. I wanted the power of the painting to come from the big, white elemental shapes, and I placed the leafy branches in a circular arrangement to keep the viewer's eye moving around the whole format."

BUFFALO

"The beautiful Mount Kilimanjaro rises in the background of the setting of Buffalo at Amboseli, *but I was more interested in conveying the detail and texture of this old buffalo's own habitat—the trees, stumps, grasses, dust, and mud that surround him in the late-afternoon light. As often happens, while I was painting I found a shape that interested me and that became a theme in the picture—a sickle shape that appears in the buffalo's nostril and in his horn. This is echoed in the shadow of his horn on his flank and in another shadow on his rump, in the dry branches in the foreground, and in the mud."*



DIK-DIKS

"I have always been attracted to intimate scenes—a few square yards of seemingly ordinary field or forest floor or scrubland, which are filled with variety and complexity if you look carefully. The dik-dik painting is one of these miniature full-fledged landscapes. The scale is small because dik-diks are small, the smallest of African antelopes, only about twelve inches high. You can see the scale of the painting by the relative size of the elephant dung, a typical feature of dik-dik habitat, as are the different grasses and bushes and the volcanic rock.

Dik-diks are attractive animals to look at and to paint. They resemble tremendously condensed, high-strung racehorses. Every muscle shows, and their anatomy and bone structure seem very tight and interlocked. They are exceptionally nervous and you usually see them either in a freeze position or else springing out of sight."

SECRETARY BIRDS

"The name secretary bird came about in the nineteenth century because the plumes emerging from the back of the bird's head reminded people of male secretaries who kept their quill pens behind their ears.

Secretary birds are raptors and are unique in that they stalk their prey while walking. They stand about four feet tall with long, rather tough, scaly legs and long necks, and they strut along in a stately way looking down for their victims, mainly snakes. When a bird spots a snake it jumps and almost dances above it, trying to immobilize it, and then strikes at the back of the neck.

When I saw these birds flapping their wings and ruffling their feathers as they settled down in their nest, the long head and tail feathers blowing and flapping in the wind reminded me more of exotic warriors wearing flamboyant, ceremonial costumes. When I painted them, I was attracted by these shapes, and by the modulation and angle of the feathers protruding and fanning out and downward."

Their costumes and hair styles modeled after the fifties American "greaser" look, Japanese youths dance in territory staked out in Tokyo's Yoyogi Park. Such groups are called Wild Drivers because they own (or aspire to own) motorcycles and cars. Their dancing may seem spontaneous, but the performance is rehearsed.

Burt Glinn; Magnum Photos, Inc.

Tokyo Rock and Role

Beneath an alien exterior, teen-age dancers cultivate a Japanese soul

by C. Scott Littleton

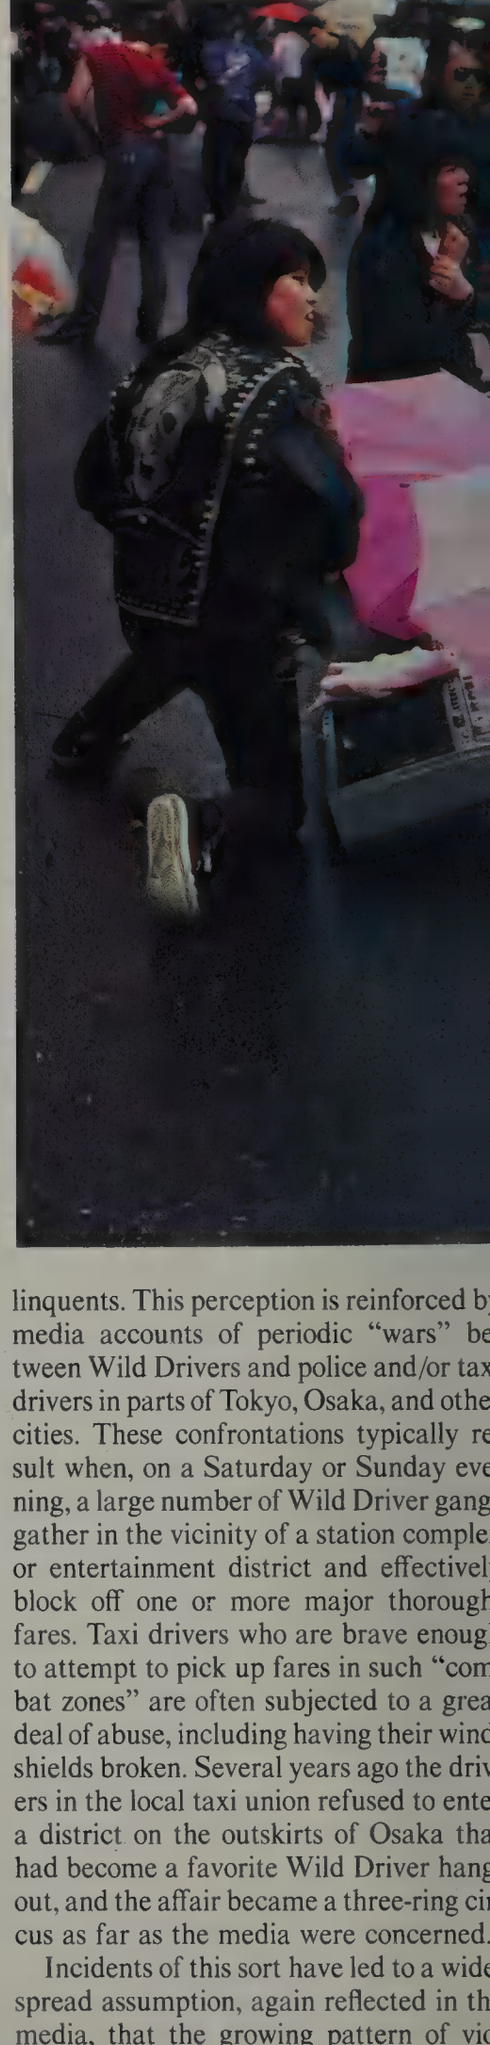
Every Sunday afternoon, weather permitting, hundreds of outrageously costumed Japanese teen-agers and young adults gather in Tokyo's Yoyogi Park to dance to tape-recorded rock music. The streets that traverse the park are closed to traffic, and a vast throng of spectators, including bemused members of the older generation, descend on the area, which is immediately adjacent to the former Olympic sports complex. Since its inception in the early spring of 1980, the Yoyogi scene has become a major tourist attraction not only for Tokyoites but also for foreigners. Tour buses now regularly include a stop at Yoyogi in their Sunday afternoon itineraries. The Japanese media, especially that portion aimed at a youthful audience, have also exploited the show. To be sure, other groups, ranging from political parties to the Japanese Hare Krishnas, also make use of Yoyogi Park on Sunday afternoons, as do a great many roller skaters, skateboarders, and high school and college drill teams, each of which occupies its own territory. But the dance groups are the main attraction.

The Yoyogi scene is not as chaotic as it might seem at first glance. The dancers are divided into small groups, ranging in size from five or six to twenty-five or thirty people. Each group supplies its own stereo tape deck and stakes out a territory within the confines of the park. These territories are jealously guarded, and the same groups tend to return week after week to the same locations. The local authorities, who otherwise keep a low profile, have imposed a permit system, and polite but efficient policemen regularly check the groups' credentials. Thus, spontaneous, individual dancing is effectively discouraged. Even here, where nonconformity appears to reign supreme, the deeply ingrained Japanese habit of subordinating the individual to the group is sustained. The Yoyogi dancers may contrast sharply with the bland image generally projected by the dark-suited "salarymen," but they are no less organized.

In the fall of 1980, when I first observed the scene, groups were divided into two distinct and mutually exclusive *zoku*, or "tribes": the *Bōsōzoku*, or "Wild Driving

Umbrellas protecting their tape equipment, a group of girls executes a carefully choreographed dance routine. All-female Wild Driver groups represent a new development in the Yoyogi scene.

Ethan Hoffman; Archive Pictures



The members of a Wild Driver group rest between dances. The forbidding emblems on their jackets imitate those of American motorcycle gangs.

Tom Ives; Black Star

Tribe" (sometimes also referred to as the *Amegurazoku*, from the title of the film *American Graffiti*) and the *Takenokozoku*, or "Bamboo Shoot Tribe." The *Bōsōzoku* are readily identifiable by their 1950s-style clothing and hair styles—shiny black pants or jeans, pointed shoes, gang jackets, and (most often) longish, greasy hair for the boys; pastel cardigan sweaters, pleated skirts, saddle shoes, and large hair bows for the girls. They look as if they had just stepped out of a somewhat blurred print of *West Side Story*.

The *Takenokozoku*, on the other hand, take their name from a popular boutique in the exclusive Harajuku district, immediately adjoining Yoyogi Park. The boutique sells the quasi-traditional costumes that serve to identify the tribe's members. These costumes, consisting for the most part of colorful, loose-fitting robes and pantaloons, are highly individualized and unisex in design. They are frequently complemented by elaborate facial makeup. The resultant image is neither Western nor exclusively Japanese; instead, what emerges is a kind of generalized Asian fantasy that, like all fantasies, is theatrical in feeling. (Unlike the Wild Drivers, the Bamboo Shoots usually do not wear their distinctive clothing on the street. They bring it with them in large shopping bags, changing after they get to the park—often behind a convenient bush.)

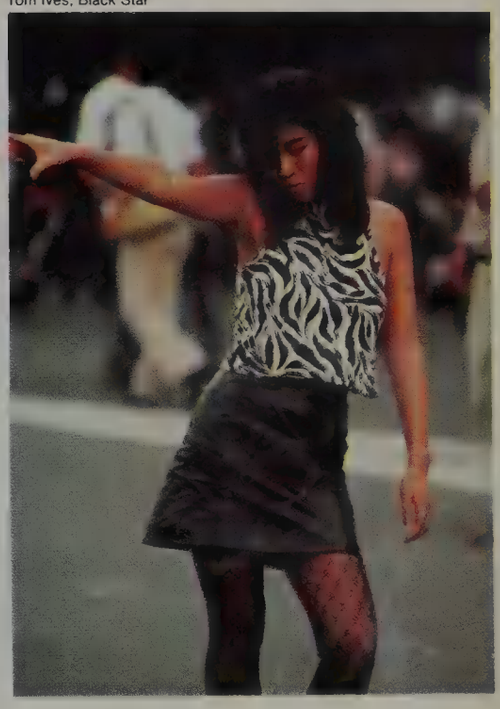
As the senior of the two tribes, both in average age and in the length of time they have been on the scene, the Wild Drivers generally occupy the more desirable locations closest to the park entrance and nearby Harajuku Station. This is in accordance with deep-rooted Japanese custom. To the best of my knowledge, the label *Bōsōzoku* first surfaced about a decade ago, and today it covers a range of groups, from innocuous dancers to antisocial gangs. All of them share a self-image derived from American motorcycle gangs and car clubs as depicted in films and on television. Most of the Wild Drivers own (or aspire to own) motorcycles, in particular, large Hondas and Kawasakis, and part of the official rationale for allowing the dance groups to use the park seems to have been to reduce the incidence of "low riding," drag racing, loitering, and other illegal activities along a nearby boulevard on Sunday afternoons. (Until recently, the Wild Drivers were exclusively male, and the female role was a subsidiary one. In the last year or so, however, several all-girl groups have surfaced, both at Yoyogi and on the streets.)

Many in the establishment see all Wild Drivers as violence-prone juvenile delinquents. This perception is reinforced b media accounts of periodic "wars" be tween Wild Drivers and police and/or tax drivers in parts of Tokyo, Osaka, and othe cities. These confrontations typically re sult when, on a Saturday or Sunday eve ning, a large number of Wild Driver gang gather in the vicinity of a station comple or entertainment district and effectivel block off one or more major thorough fares. Taxi drivers who are brave enoug to attempt to pick up fares in such "com bat zones" are often subjected to a grea deal of abuse, including having their wind shields broken. Several years ago the driv ers in the local taxi union refused to ente a district on the outskirts of Osaka tha had become a favorite Wild Driver hang out, and the affair became a three-ring ci cus as far as the media were concerned.

Incidents of this sort have led to a wide spread assumption, again reflected in th media, that the growing pattern of vio lence in junior high schools—assaults o teachers and so forth—is somehow linke to the *Bōsōzoku* phenomenon. The Wil

Although a fifties look dominates, contemporary fashions also appear at Yoyogi Park.

Tom Ives; Black Star



Drivers, who generally come from blue-collar families, are widely considered to be dropouts from the educational system, with its entrance examinations that haunt Japanese young people from kindergarten to university. (Many Japanese social scientists hold the pressures of the "examination hell" responsible for much of the current upsurge in youthful rebellion and delinquency.) The *Bōsōzoku* are also perceived as rejecting the work ethic that so pervades the mainstream Japanese mentality. They are frequently compared to the student radicals of the late sixties and early seventies, who regularly engaged in violent street demonstrations. A handful of the groups have joined forces with the radical right and its ubiquitous sound trucks, but this aspect has been blown out of proportion by the Japanese media.

The great majority of the Wild Drivers who dance at Yoyogi are not connected with the groups that have become so notorious in Osaka and elsewhere (for this reason, some of the dancers prefer the name *Amegurazoku,* but most share at least identification in name with the "hard-core" *Bōsōzoku* gangs). Save for traffic and relatively minor "status" offenses such as curfew violations, the Wild Drivers of my acquaintance have no criminal records and, for the most part, are either full-time senior high school students or are gainfully employed, albeit outside the lifetime-employment system. Apart from their costumes, many of them both look and act like typical Japanese teenagers, up to and including short haircuts (sometimes insisted upon by parents and/or school authorities). When not "on stage," as it were, they often display that thoroughly disarming, open-faced grin that one encounters so frequently among contemporary Japanese young people.

Nevertheless, the Wild Drivers' aggressive demeanor and American-inspired dance routines (Jerry Lee Lewis is a big favorite) strike the majority of adult Japanese as decidedly alien. This assessment is reinforced by the often bizarre English words and phrases emblazoned on their jackets, including names such as "Black Shadow" or "Dirty Angels" that imitate those of American street gangs. As someone from my Tokyo neighborhood saw it, the Wild Drivers have modeled themselves after the dregs of American popular culture and, in flaunting this negative life style at Yoyogi Park, have put themselves beyond the pale of respectability.

Yet these apparent outcasts, many of whom do look, at first glance, like refugees from an East Los Angeles street gang, are wholly "Japanese" in much of their behavior and deportment. Absolute group loyalty and devotion are demanded, and the interaction among group members conforms for the most part to the hierarchical pattern characteristic of Japanese society. Thus, status differences based on relative age and seniority in the group are readily apparent. Younger members defer to older members, and all concerned can be observed bowing to one another with about the same frequency as members of any comparable Japanese group, establishment or otherwise.

The dance routines, although American-inspired, are thoroughly rehearsed, and as in some traditional Japanese dances, males and females typically dance in two lines facing one another. Occasionally a couple will execute a fifties-style routine, and now and then an individual

Despite their choice of American rock music and alien costumes, Wild Drivers often dance in lines, a practice characteristic of certain traditional Japanese dances.

Rene Burri; Magnum Photos, Inc.

will perform solo. But none of these actions is truly spontaneous. Moreover, the Wild Drivers' clothing is always clean and neat, and their faces invariably seem freshly scrubbed—a far cry from those of their American role models.

The dancing and other activities are sometimes accompanied by sneering facial expressions and aggressive posturing. But these gestures are purely symbolic, and there is little if any actual violence here, even in disputes over territory. Confrontations are themselves highly ritualized. On one occasion, the Wild Drivers moved into Bamboo Shoot territory to set up a live band, and members of both tribes faced off. I witnessed the confrontation in the company of several other American spectators, one of whom remarked that if a similar situation were to arise in our culture, it would almost certainly end in a riot. On this occasion, however, after exchanging relatively mild insults, the opponents bowed to one another, and the Bamboo Shoots simply left the area. The whole arrangement had been worked out in advance with the authorities, and the leaders of the respective groups were already in agreement.

Most *Bōsōzoku* I encountered—at least the ones who dance at Yoyogi—expect eventually to become part of the mainstream, at least in some capacity. Hiroshi, for example, a crew-cut eighteen-year-old who belongs to the Dirty Angels, claims that he's never had a confrontation with either taxi drivers or the police, and I have no reason to doubt him. Like perhaps the majority of the dancers, Hiroshi and his fellow Angels, all eight of them, come to Yoyogi almost every Sunday to dance and hang out. Except possibly for some illicit street racing (all but one of them own bikes), this seems to be the limit of their participation in the *Bōsōzoku* scene. Some have suggested that Wild Drivers "graduate" to membership in the *Yakuza,* the Japanese Mafia-like crime syndicate. This may be true elsewhere, but none of the dancers I came to know gave any indication that they planned such a career. Hiroshi plans to enroll in a Tokyo technical institute after he finishes high school.

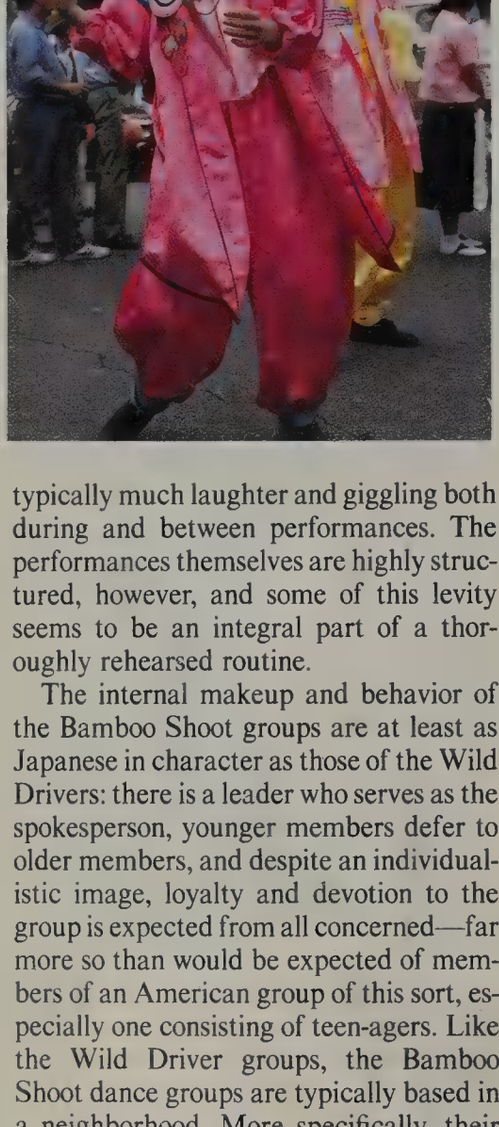
Unlike the *Bōsōzoku,* the *Takenokozoku,* or Bamboo Shoot Tribe, is composed exclusively of middle and high school students under the age of eighteen. In their demeanor, the Bamboo Shoots generally have an aura of what can best be described as amiable ecstasy. Their facial expressions are animated, in contrast to the masklike expressions usually worn by Japanese in public places or the grimaces affected by the Wild Drivers. There is

The hair style, glasses, and string tie of the male half of a Wild Driver couple recall the look of the late American rock star Buddy Holly. The girl, like most associated with the Wild Driving "tribe," affects a feminine look reminiscent of the fifties.

Tom Ives; Black Star

Ecstatic expressions are typical of the Bamboo Shoots, a tribe of boys and girls who, along with the Wild Drivers, dance in Yoyogi Park.

Hidefumi Kawada



The Bamboo Shoots prefer Asian-inspired costumes and Japanese rock music. Their name is taken from a popular boutique that sells unisex clothing.

Rene Burri; Magnum Photos, Inc.

typically much laughter and giggling both during and between performances. The performances themselves are highly structured, however, and some of this levity seems to be an integral part of a thoroughly rehearsed routine.

The internal makeup and behavior of the Bamboo Shoot groups are at least as Japanese in character as those of the Wild Drivers: there is a leader who serves as the spokesperson, younger members defer to older members, and despite an individualistic image, loyalty and devotion to the group is expected from all concerned—far more so than would be expected of members of an American group of this sort, especially one consisting of teen-agers. Like the Wild Driver groups, the Bamboo Shoot dance groups are typically based in a neighborhood. More specifically, their members may come from a particular middle school. One Bamboo Shoot girl, for example, told me that she and her friends had known one another since grammar school, and that they just naturally came together when the fad began.

The Bamboo Shoot groups usually dance in a circle, males and females intermingled, and their hand movements are graceful rather than jerky. There is a softness here, expressed in the billowing robes and smiling, heavily made-up faces, that contrasts with the *macho* image projected by the Wild Drivers. The routines are much more carefully choreographed, and the whole effect is extremely balletic. Instead of the fifties American rock favored by the Wild Drivers, the music is for the most part indigenous Japanese rock, typified by the sound of the Yellow Magic Orchestra, which has appeared on stage dressed in *Takenoko* style.

The journalist Ian Buruma, a cogent commentator on the contemporary Japanese scene, suggests that the Bamboo Shoots, who generally seem to come from middle-class "salaryman" families, are hypertraditionalists and that their overall image is consciously derived from ancient Japanese prototypes. Their dance style is reminiscent of traditional Japanese dances—except for the animated facial expressions and relaxed attitude of the dancers. Moreover, the heavily ritualized preperformance behavior, in which the leader delivers a short speech exhorting his or her fellow Bamboo Shoots to give a good performance and to uphold the honor of the group, after which all bow and clap their hands several times, recalls the sort of behavior one might expect to see at a neighborhood Shinto shrine festival. The attention to details of costuming and performance, and the long hours spent in rehearsal, are equivalent to what is required by any traditional Japanese ceremony or discipline.

But the end result is by no means wholly Japanese. Western elements appear in the individualized costumes and animated behavior of the dancers, as well as in the basic style, if not the immediate source of their music. One is sometimes reminded of the flower children of the late sixties

The generalized Asian fantasy projected by the Bamboo Shoots often includes heavy makeup. This boy's appearance is a reminder that in the seventeenth century, outrageously costumed youth—some impersonating females—helped inspire the creation of Japan's Kabuki theater.

Hidefumi Kawada

Like them, the Bamboo Shoots are consciously rejecting, at least in the context of their dances, the mainstream mode—in this case the formality, stiffness, and lack of individuality that generally characterize contemporary Japanese society.

The Yoyogi scene has precedents in the history of Japanese popular culture. For example, in the early seventeenth century, at the beginning of the Tokugawa era, groups of youths, garbed in what was then considered outlandish clothing, were wont to gather in teahouses, gardens, and other public places in Edo (present-day Tokyo) and dance or otherwise carry on in ways that outraged the sensibilities of the Tokugawa establishment. Such persons, generally the sons of merchants and lower-ranked samurai, were referred to as *Kabukishu* (from the verb *kabuku*, "to behave outrageously"), and as in the case of the *Bōsōzoku* and the *Takenokozoku*, their antics were eventually confined to certain specific locations. The *Kabukishu* style was copied—and then modified—by professional actors, who turned it into a true art form that came to be called the Kabuki theater. Unlike the older, more aristocratic No drama, Kabuki, with its lavish sets, exaggerated acting style, and "outrageous" dances and costumes, appealed to the same segment of society that had given rise to the *Kabukishu*. It even kept intact the latter's penchant for female impersonation, in the now-classic tradition of the *onnagata*, or male actor who plays female parts.

This is not to imply that the behavior of either the *Takenokozoku* or the *Bōsōzoku* will ever achieve social acceptance as an art form. The great majority of *zoku*, past and present, are ephemeral. A generation ago it was the *Taiyōzoku*, or "Sun Tribe," whose members wore Hawaiian shirts and dark sunglasses, that outraged social critics. The Bamboo Shoot phenomenon already seems to be well on the wane. The Wild Drivers are still going strong, but small groups of break dancers have already begun to make their appearance, and other embryonic *zoku*, including what the Japanese have come to call the *Punku*, or "Punkers," are waiting in the wings, as it were, to do their own thing at Yoyogi and elsewhere.

Another precedent in Japanese culture is the neighborhood Shinto shrine festival, or *matsuri*, wherein groups of ecstatic, albeit well-organized, young people bob and weave in unison as they carry portable shrines. The line between conformity and rebellion can become thin in such traditional religious performances, especially as the beer and sake flow. Among the more notorious examples of festivals gone wild were the *matsuri* associated with the *Eijanaika*, or "Who Cares about Anything?" movement of 1866, when inebriated youthful adherents danced themselves into a frenzy and then ran through the streets of Edo shouting the movement's slogan at the top of their lungs (a more literal translation is, "Isn't it all right?").

Like the *Kabukishu* before them, and the *zoku* of modern times, the devotees of *Eijanaika* were not at war with the social system per se. Although Japan was on the threshold of economic and political changes that would wrench it into the modern world, the short-lived *Eijanaika* movement had little if anything to do with bringing those changes to pass. It was instead simply one of the many rituals of rebellion that have long been a feature of Japanese popular and religious culture.

The phrase "ritual of rebellion" was coined thirty years ago by the late South African anthropologist Max Gluckman, in a celebrated essay on African religion. He identified a category of behavior in which the participants "openly state their resentment of authority" and generally act in a fashion contrary to the norms and expectations of their society, but which challenges not the established sacred tradition but rather the distribution of power within it. Gluckman also wrote of what he called a "repetitive" social system, that is, a system in which "particular conflicts are settled not by alterations in the order of offices, but by changes in the persons occupying those offices." Both these concepts apply well to Japan.

In contrast to most other highly developed, postindustrial societies, the Japanese have clung tenaciously to a repetitive system. To be sure, a great many far-reaching political and economic changes occurred at the time of the Meiji Restoration of 1868. In the space of less than a generation, the emperor was made the central focus of political authority, a Western-style parliament and constitution were introduced, and industrialization began. But even that important event, from which the modern history of Japan is conventionally dated, was not a true revolution in the Western sense but rather an extensive reshuffling of persons and roles within essentially the same ruling class.

The overwhelming majority of Japanese share a long-standing confidence in the validity and essential correctness of their social system. That view is implicitly shared by the *Bōsōzoku* and the *Takenokozoku*, just as it was by the earlier *zoku*, even though their performances are perceived (and conceived) as countercultural. As a result, the Yoyogi scene is by no means as inherently critical of the dominant culture as its Western analogs—certain rock concerts, the streets of Berkeley, the Rembrandtsplein in Amsterdam—have sometimes proved to be. On the contrary. By projecting a rebellious and/or "un-Japanese" image in an otherwise thoroughly Japanese way, the dance groups pay homage to the vitality of the social system that produced them. □

laborate preparation is reflected in a Vild Driver group's Elvis imitation. The ttention to details and the long hours of ehearsal are equivalent to what is equired by any traditional Japanese eremony or discipline.

A female red-necked phalarope in summer plumage
Martin W. Grosnic

Philandering Phalaropes

The male red-necked phalarope incubates the eggs and protects the young, leaving the female free to court another mate

by John D. Reynolds

Each spring, as the ice disappears from prairie sloughs and arctic ponds, flocks of phalaropes take up residence in the frigid water. These colorful shorebirds chatter intensely to each other as they twist and pivot, stabbing at insects and plankton, often spinning like tops and sending ripples spiraling outward. Occasionally, this dizzying scene of feeding activity is interrupted as one female lunges at another, using her bill as a weapon. The attacked female jumps back to yield to the aggressor, which then ushers her smaller, less brightly colored mate to a less congested part of the pond. Another breeding season has begun, and the phalaropes' unusual mating system is gearing up.

In the avian world, males are typically the more aggressive sex, defending territories and courting mates, while females lay and incubate the eggs and provide much of the care for their young. This is not always the case, however. The three species of phalarope (red and red-necked, which breed in the Arctic, and Wilson's, which breeds in interior North America) all belong to the less than one percent of bird species in which the males are entirely responsible for incubation and brood rearing. This leaves the females free to be polygamous. Interestingly, of the approximately thirty species of birds in which sex-role reversal is known to occur, fifteen are shorebirds. Even within this select group phalaropes stand out: neither sex maintains a territory at any stage of the breeding cycle.

The phalaropes' reversal of sex roles during the breeding season has long aroused the curiosity of naturalists. In 1895, Daniel Giraud Elliot, curator of zoology at what was to become the Field Museum of Natural History in Chicago, wrote of the red-necked phalarope, "Early in May it arrives at the breeding grounds, and the females commence to make love to the apparently indifferent males, using all the wiles and blandishments generally employed by one of the sterner sex (when bent on like purpose) to gain the favor and secure the affection of the object of its adoration." Such anecdotal accounts of phalarope courtship were typical of those written by nineteenth-century naturalists. Ironically, some of these people, who wrote of the birds with such affection, contributed to declines in accessible populations (such as those of the red-necked phalarope in the Scottish Outer Hebrides) by shooting adults and taking eggs for personal collections.

Early descriptions have been succeeded by detailed studies of the breeding biology of all three phalarope species. These studies have revealed the extent of role reversal in these birds: males invest nineteen days in incubation and another twelve to twenty days in rearing the brood. Females, in striking contrast, contribute only the eggs (nearly always four, sometimes three) to each reproductive effort and are capable of producing a second clutch for another mate only six days later.

My own research efforts have concentrated on the red-necked phalarope, a circumpolar species that, in the New World, winters at sea, primarily off the coast of Peru, and breeds in low arctic regions of Canada and Alaska. I spent the past three summers studying them at La Pérouse Bay, 25 miles east of Churchill, Manitoba, on the northwest coast of Hudson Bay. My study area was centered on the confluence of the Mast River and Hudson Bay. The water in this river delta, which varies from a few inches deep to just over hip wader level, flows around hundreds of small is lands within my 0.8-square-mile stud area. Depending on the year, from 75 t 175 red-necked phalaropes nest ami sedges and dwarf willows on these island and feed along the shores or in open wate courses. Nests belonging to different pair may be only four feet apart or hundreds o yards from the nearest neighbor.

At La Pérouse Bay, as with population of phalaropes elsewhere, the males' paren tal duties limit them to a maximum of on brood per season, while females may la two successive clutches for two differen males, a phenomenon termed serial poly andry. Eight percent of females at La Pé rouse Bay are polyandrous, with the res being monogamous or, in some cases, ex cluded from breeding. This percentage o polyandry is probably representative fo red-necked and red phalaropes. Polyandr still has not been documented among Wi son's phalaropes. Their breeding behavio is similar to that of the other two species however, and recent studies by Mar Colwell of the University of North Dakot suggest that polyandry probably occurs at least occasionally, in this species, too.

In all three species, the number of mal and female breeders is usually equa From the females' point of view, males ar thus a major limiting factor in reproduc tion and are a commodity worth fightin for. At La Pérouse Bay, aerial chases wit two or more female red-necked phala ropes noisily pursuing a harried male ar common. They often culminate in violen fights, with the females tumbling acros land or water in a flurry of wings and dan gling legs, jabbing each other with the bills. The combatant that gains the uppe hand in these battles frequently covers th submissive male with her outstretche

wings as she wards off the blows of the other females.

Phalaropes provide more than entertainment to those who watch their courtship antics. As the proverbial exception to the rule, they make it possible to test a number of general theories about behavioral differences between the sexes of animals. I have been particularly interested in differences between males and females in the time of arrival at the breeding grounds and in the tendency of individuals to return from one year to the next to the same breeding locations.

Studies of migratory bird species have shown that when males and females arrive at breeding grounds at different times, the territorial sex—normally the male—is the first to arrive. This is generally interpreted as a behavioral adaptation for competing with other males for territories and mates. Arriving early increases the chance of acquiring a territory, without which there is usually no chance of attracting a female. But what would one predict for the red-necked phalarope's mating system, which differs from most in that, one, females, rather than males, are the more competitive sex, and, two, they defend their mat directly, rather than through control territories?

To answer this and other questions, had to devise a way to capture the phal ropes so they could be given individual recognizable combinations of color band After trying a variety of traps and mis netting techniques, I found that the be method employed a small net on the en of a twelve-foot collapsible fishing pol After practicing on bubbles floatin downstream, I became adept at flickin the net over the birds as they swam. The

B. Lyon; Valan Photos

Left: A male phalarope stands guard over his day-old young. Although phalarope chicks are mobile and able to feed themselves within hours of hatching, most fathers care for them for the first week, leading them from one feeding spot to another and uttering warning cries when a predator approaches. Chicks are threatened by such dangers as the parasitic jaeger, below, which preys on both eggs and young.

James M. Richards

uld then be quickly banded, measured, nd released without harm.

In three out of four years (data from 981 were collected by Margaret Stalker Queen's University), more female than ale phalaropes were recorded during the rst week of spring arrival; by the time esting had begun, there were about as any males as females on the breeding rounds. Thus, despite the lack of territo- ality, females preceded males, which caught up" a few days later. Observa- ons of banded phalaropes revealed that ne majority of the birds censused daily were local breeders rather than migrants.

There is more than one explanation for why females precede males. One possibility is that females, which weigh 12 percent more than males, can more easily withstand the harsh conditions of early spring. However, in many species of monogamous sandpipers, females are slightly larger than males, yet males still arrive first to establish territories. The "body-size hypothesis" is thus weak as a general argument for sex difference in arrival times.

The key to the phalaropes' departure from this pattern probably lies in their reversed sex roles. Even without the need for a territory, females that arrive early probably maximize the number and quality of males for which they can compete. "The early bird gets the sperm," as David Lank of Queen's University put it. Males are usually snapped up by a female within a day of reaching the breeding grounds, and the scramble among females for mates leaves eligible males in short supply. Hence late-arriving females lose potential mates to females that preceded them, and some females at La Pérouse Bay are unable to obtain any mates at all. Since sequential polyandry is limited by availability of males and by the length of the breeding season, the potential for bigamy in this species is enhanced by pairing (hence arriving) as early as possible. Concurrent studies by Mark Colwell of Wilson's phalaropes in southern Saskatchewan reveal a similar pattern of females preceding males to courtship areas.

There are, of course, constraints on how early phalaropes can arrive. In particularly harsh and cold years, water may remain frozen and aquatic insects unavailable beyond the phalaropes' usual arrival time. This unpredictability of arctic springs requires that the birds be flexible. In 1983, for example, females and males appeared on the breeding grounds at the same time: this was one of the latest springs on record for the Churchill area. Ice jammed the entire river delta until early June, instead of its more usual melting time in mid-May. Forced to delay their arrival by two weeks, most of the phalaropes were already paired when I first saw them. Presumably, pair formation took place south of the region while they were waiting for the ice to clear.

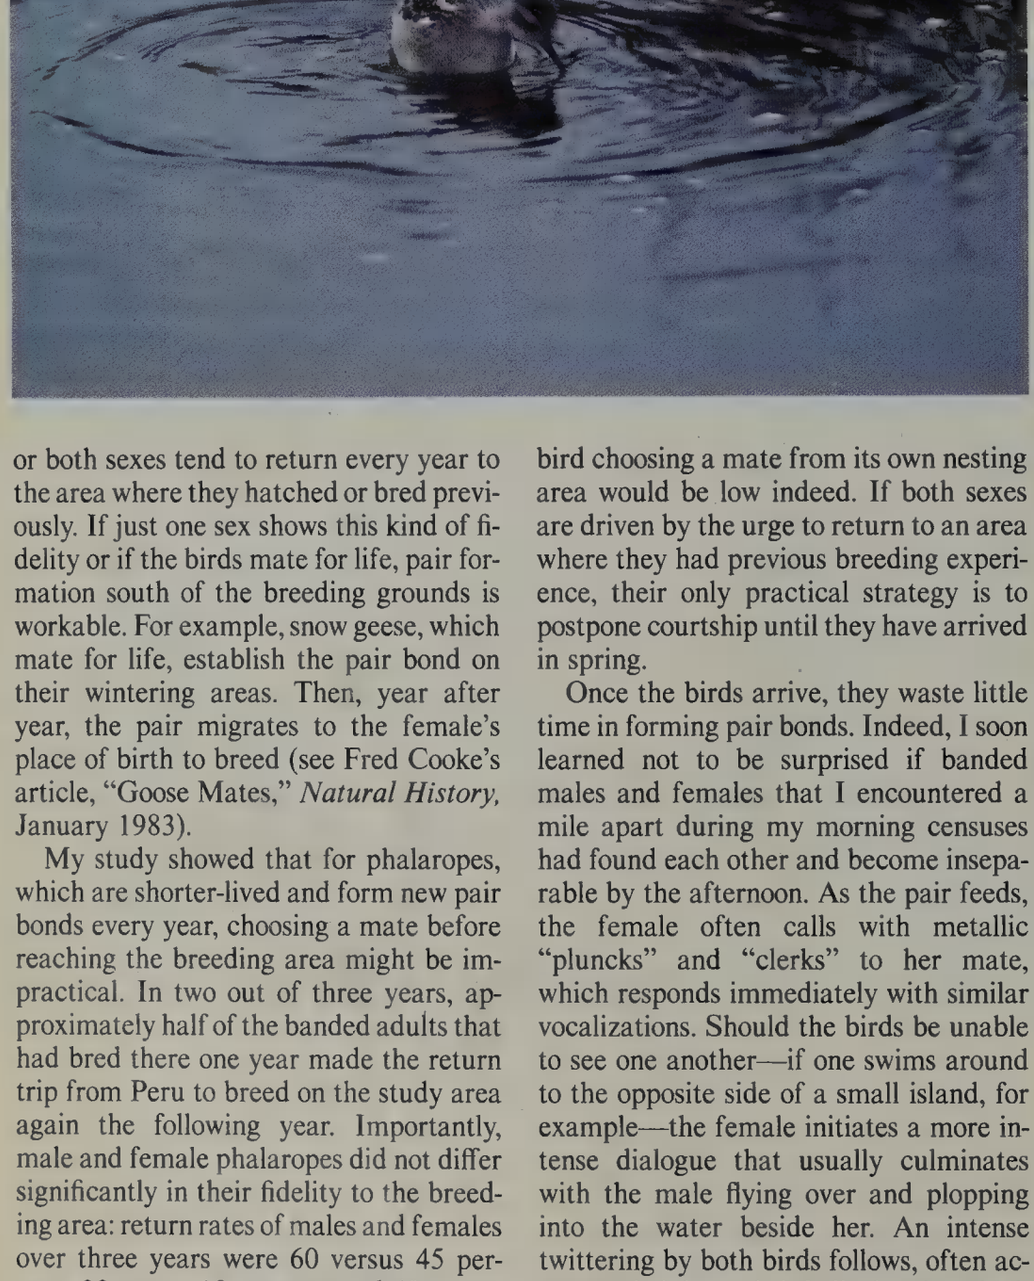
If pairing en route is possible, why don't phalaropes habitually choose their mates during migration or even on their tropical wintering areas? The answer may be that such a scheme would lead to a clash of interest if the two members of a pair had different ideas as to the best place to breed.

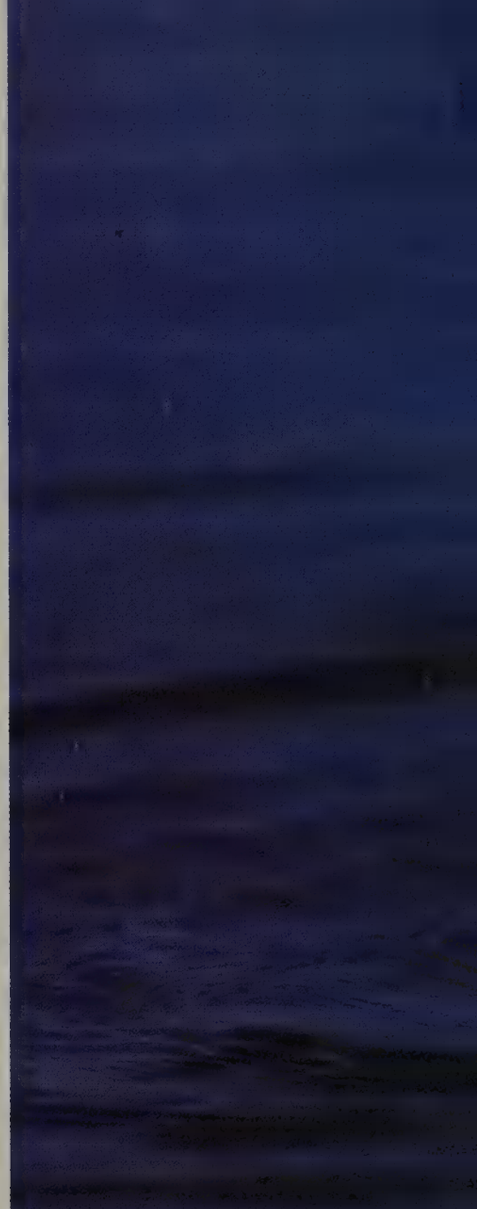
In most species of migratory birds, one

Mildred McPhee; Valan Photos

Buoyed up by a layer of down and dense breast and belly feathers, phalaropes sit lightly on the water. The birds have lobed toes, an adaptation for swimming shared by many other aquatic birds. Phalaropes, like the red-necked juvenile, below, also use their toes to help them spin around in little circles, an action that stirs up the invertebrates on which the birds feed. Wilson's phalaropes, right, have been clocked at sixty spins a minute.

R.P. Sheridan





or both sexes tend to return every year to the area where they hatched or bred previously. If just one sex shows this kind of fidelity or if the birds mate for life, pair formation south of the breeding grounds is workable. For example, snow geese, which mate for life, establish the pair bond on their wintering areas. Then, year after year, the pair migrates to the female's place of birth to breed (see Fred Cooke's article, "Goose Mates," *Natural History,* January 1983).

My study showed that for phalaropes, which are shorter-lived and form new pair bonds every year, choosing a mate before reaching the breeding area might be impractical. In two out of three years, approximately half of the banded adults that had bred there one year made the return trip from Peru to breed on the study area again the following year. Importantly, male and female phalaropes did not differ significantly in their fidelity to the breeding area: return rates of males and females over three years were 60 versus 45 percent, 20 versus 18 percent, and 43 versus 61 percent, respectively. Furthermore, both sexes tended to nest in the same particular parts of the river delta from one year to the next. Since phalaropes winter and migrate in flocks that may number into the thousands, the odds of a migrating bird choosing a mate from its own nesting area would be low indeed. If both sexes are driven by the urge to return to an area where they had previous breeding experience, their only practical strategy is to postpone courtship until they have arrived in spring.

Once the birds arrive, they waste little time in forming pair bonds. Indeed, I soon learned not to be surprised if banded males and females that I encountered a mile apart during my morning censuses had found each other and become inseparable by the afternoon. As the pair feeds, the female often calls with metallic "pluncks" and "clerks" to her mate, which responds immediately with similar vocalizations. Should the birds be unable to see one another—if one swims around to the opposite side of a small island, for example—the female initiates a more intense dialogue that usually culminates with the male flying over and plopping into the water beside her. An intense twittering by both birds follows, often accompanied by a brief display in which they lower their heads and aim their needlelike bills at each other. When this display is followed by a sharp jab by the female and a loud protest by the male, I can't help translating the female's side of the confrontation as "Stay in sight or else!" Lacking a territory, the female ca not enforce a large buffer zone around h mate, so guarding him closely is essenti for defending him from other females.

From one to two weeks after pair form tion, the male red-necked phalarope us his feet to scrape out a shallow nest on t ground near a pond or stream. The ne may be fairly exposed or set in a tussock sedge amid low shrubs. The female la one egg daily until the clutch is co pleted. At the time of each egg laying, t male performs a distinctive ritual. Stan ing a few inches to half a yard from t nest, often just at the water's edge, flicks small leaves and grasses over h shoulder with his bill, roughly toward t nest. I have counted up to sixty-two these tosses in a minute, and the proc dure may continue for the entire five to f teen minutes required by the female to l the egg. Sometimes the male mecha cally goes through the motions without a tually picking anything up. Many oth shorebirds and other ground-nesting bir

xhibit this "sideways-throwing" behavor, and in some species it has a clear funcion in lining the nest. If that is its prinipal function in phalaropes, it certainly eems inefficient! I suspect it serves prinarily as a nesting display.

During the egg-laying period, the males evelop brood patches—two oval patches f bare skin on either side of the breast hat are used to apply heat directly to the ggs during incubation. Males dutifully egin sitting on the eggs after the third or ourth one has been laid. If the nest escapes the attention of predators such as erring gulls, arctic and red foxes, weaels, and even, rarely, polar bears, the eggs atch nineteen days later. Within a few ours of hatching, the chicks, whose legs re almost as long as those of adults, can otter around and feed themselves. Most nales are attentive fathers, brooding oung regularly during the first week, givng vocal instructions to come to him or ide, and leading them from one island to nother to find safe feeding locations.

Not all males are so attentive, however. Their tendency to return from year to year allowed me to become well acquainted with some individuals, and one of the males banded in 1983 seemed to be the epitome of a poor parent. Instead of paying constant attention to his young and giving alarm calls when I approached, he seemed oblivious to both them and me. Frequently, I found his brood with no sign of him anywhere. But much to my surprise, he was one of the only males to raise all four of his young to the flying stage that year. Usually, broods lose at least one chick to predators, such as parasitic jaegers—souped-up relatives of gulls, which work in pairs, cruising slowly over the meadows, scanning for young phalaropes and other birds. The following year the same male nested only forty yards from his previous site and behaved exactly the same way, apparently ignoring his young. Once again he successfully reared them all (in this case his mate had provided only three eggs). This consistency of behavior and its apparent success forced me to wonder just what I knew about being a good phalarope parent, anyway.

For the female phalarope, the question of being a good parent does not even arise. After the eggs are laid, she completely ignores the nest and her former mate. At La Pérouse Bay some females disappear immediately after laying the eggs, presumably traveling along the coast of Hudson Bay to molt and feed in preparation for their southward migration. Others stay, share small home ranges with other females, and spend a great deal of time harassing incubating males. In a typical encounter, a female swims up to the shore of a small island and approaches a male (not her own) sitting on a nest. The male flies toward her, making a distinctive squeaking sound and twisting in the air as he lunges at her with his bill. The female retreats, and the male zigzags through the air as if in only partial control of his steering. Sometimes, he dives suddenly into the vegetation. The female resolutely flies or swims to him again, and the whole sequence is repeated. I have seen males beset by as many as eight females at once!

My initial thought—somehow attractive in its gruesomeness—to explain this harassment was that the females were attempting to destroy eggs incubated by males other than their own. This would make the males available to mate with them. Such behavior is not unknown among birds: Donald Jenni and Martyn Stephens observed just such destructive behavior in polyandrous jaçanas in Costa Rica. The females mated with the newly available males. I have no direct evidence of infanticide ("ovicide"?) by female phalaropes, although the ultimate goal of obtaining mates probably still applies. Females seem to ignore the nests, even though males often leave them unprotected as they hide or retreat. The most persistent females pursue males into the vegetation, walking slowly through the tall sedges and craning their necks as they peer around. Sometimes a male may wait for half an hour until the females have lost interest. Then he torpedoes through the water to his nest, with his body half submerged.

This arctic pond, dotted with small islands, is typical nesting habitat for the red-necked phalarope. The red phalarope also nests in the Arctic, while Wilson's—like the male at right—breeds in the wetlands of central and western North America.

James M. Richards

The males' attempts to dissuade the females' overtures are usually successful. When incubation *is* disrupted and new pair bonds formed subsequently, predation is generally the cause. Once a nest has been robbed, the male may be picked up for a renesting attempt within one day, sometimes by a female with another male caring for her first clutch elsewhere.

Much is known about the breeding biology of phalaropes, but the evolution of their mating system remains somewhat of a mystery. Shorebirds as a group seem to have cornered the market on role reversal, with about half of the avian cases occurring in this suborder. Even monogamous shorebirds possess several characteristics that preadapt them toward sex-role reversal, and it seems likely that the phalaropes' ancestors displayed these.

The first preadaptation is the widespread tendency of male shorebirds to share half the incubation duties and provide all or nearly all care of the young. Since the young are precocial, that is, they are highly mobile and can feed themselves within hours of hatching, parents do not need to provide as much care as in many other avian groups, and uniparental care can evolve more easily.

Another attribute of shorebirds that may lower the threshold for the evolution of sex-role reversal is their fixed clutch size. In many species of birds, females can increase the number of eggs laid per nest if food conditions are favorable. The invariant clutch size of shorebirds, however, means the female's best option for capitalizing on abundant food resources is to make a fresh start with a new nest, leaving the first in the care of the male.

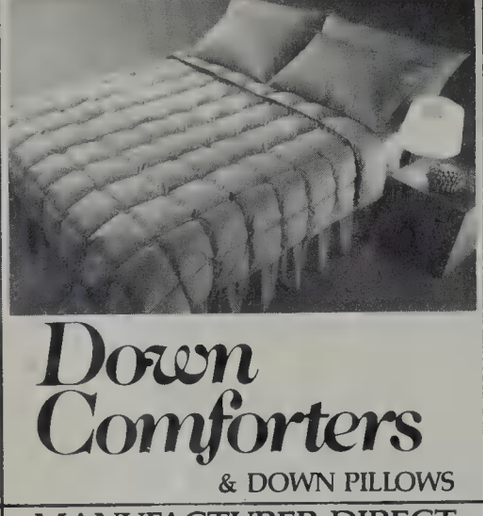
Armed with these considerations and a comprehensive review of shorebird mating systems, James Erckmann of the University of Washington concluded that when reproductive efforts and potential for further mating opportunities are essentially equal between the sexes, male uniparental care and sex-role reversal may be as likely to evolve as female uniparental care. There is no a priori reason to think that females are less likely than males to exploit opportunities for maximizing their reproductive output.

In the case of the phalaropes, the nature of the food supply may have played a key role in the evolution of role reversal and lack of territoriality. The aquatic invertebrates that form the bulk of their diet often occur in ephemeral bursts. On small ponds along the coast of Hudson Bay, for example, clusters of emerging midges and other aquatic insects occasionally gather on the water's surface in densities sufficient to attract phalaropes from one or two miles away. A few days later these ponds may be vacant while others provide an invertebrate feast. Thus, establishing and defending territories may usually be impractical for phalaropes. In especially good years, the females' freedom from incubation may permit them to exploit food resources and compete for additional mates.

What about the phalarope's appearance? The reversal of plumage coloration and size dimorphism can probably be ascribed safely to the evolutionary process Darwin termed sexual selection. This operates on characteristics that help organisms obtain mates but are of little value, or possibly even disadvantageous, in day-to-day survival. Brighter and bigger females may simply be more successful in attracting and winning mates. (Dull plumage in males, on the other hand, probably evolved through natural selection; crypti coloring should be advantageous durin incubation.)

Sexual selection is not limited to phys cal traits. Indeed, it is also the basis of th argument for why females precede male to courtship areas in spring: females ma enhance their ability to win mates b maximizing the length of time they spen competing for them. Animals with mor conventional mating systems, in whic males compete for females, are under sim ilar pressures, but in these species, sexu selection acts more strongly on males.

Studies of phalaropes are sheddin light on the relationships between soci systems and behavioral differences b tween the sexes, but challenging que tions remain. We don't know, for exam ple, the precise mix of ecological an historic circumstances that leads to th evolution of sex-role reversal. And sinc female phalaropes readily lay tw clutches but are limited by availability mates, why not incubate the secon clutch themselves, as is done by a fe other species of shorebirds? This wou double their annual reproductive outpu As we tackle these questions, we a learning not only about phalaropes b also about some of the ground rules th govern behavioral ecology in general.



Down Comforters
& DOWN PILLOWS

MANUFACTURER DIRECT

Destined for heirloom status! If you take pleasure in fine attention to detail, the hand-crafted Square Stitch Down Comforter is a first class choice. Each hand-stitched, hand-sewn 8" square is carefully constructed to allow maximum down loft. Our finely woven, wrinkle resistant down proof poly/cotton fabric surrounds the finest European down.

We're America's largest retailer of down comforters and down pillows, manufacturing premier quality down products in La Crosse, Wisconsin since 1911. By selling directly to you, we eliminate the middleman and retail markup, saving you 50% and more off normal retail. **Our Guarantee:** If for any reason you are not completely satisfied with your purchase, please return it for a full refund. Delivery: We ship within 24 to 48 hrs.

Last Chance for the Ivorybill

by Lester L. Short

Cuba is an island republic off-limits for the moment to Americans other than journalists and those conducting scientific research. It is the home of twenty-one endemic species of birds, many of which are little known. Among them is the world's last ivory-billed woodpecker (*Campephilus principalis*). One of its endemic species is the spectacularly patterned Cuban green woodpecker (*Xiphidiopicus percussus*). Having studied woodpeckers for several decades and written a monograph titled *Woodpeckers of the World*, I had observed at least one species of all twenty-six genera of woodpeckers but one—*Xiphidiopicus*, the genus composed solely of the Cuban green woodpecker. Neither had I seen the ivorybill. I was therefore delighted when, in August 1984, I received a telephone call from Comandante Universo Sánchez Alvarez, director of Cuba's Bureau of Flora, Fauna, and Protected Areas, inviting me to help search for and study the ivory-billed woodpecker.

After accepting the invitation, I requested that George Reynard, a bioacoustician who has visited Cuba six times and is preparing phonograph records on the songs of Cuban birds, be allowed to join me. This proposal was accepted by the Cuban authorities.

To get to Cuba we first had to pick up a Cuban visa in Montreal, which we did in mid-February. Then we flew from Toronto to Varadero, a peninsula of beaches and resorts on Cuba's north coast, seventy-five miles east of Havana.

Because Cuba's leading ornithologist, Orlando Garrido (a former tennis player of Wimbledon caliber), was out of the country, we were assigned a knowledgeable young biologist, Giraldo Alayón, a specialist in both spiders and birds, who heads a team surveying bird populations in western Havana Province. We laid plans for our studies, and early on February 20 the three of us flew to Guantánamo, some 600 miles farther east.

Aided by Misael Fernandez, local chief of the Cuban Institute of the Friendship o Peoples, which smooths the way for all for eign visitors, we visited the Zoologica d Piedra, a "zoo" of thirty-five, larger-than life rock carvings of animals, all in actio poses, sculpted by Angel Iñigo. Thes works are scattered about a wooded ravin full of birds. Here we observed and re corded the voices of several species, givin special attention to the West Indian red bellied woodpecker and the local race o the northern flicker. (The latter, unlike it continental relatives, feeds largely in tree and only occasionally hops about on th ground.)

One of the notable facts about Cuba birds is the great number of North Amer can wood warblers that winter on the is land (that is, they spend most of the yea from September to April, in Cuba but d not breed there). In pineland habitats, fo instance, half the birds to be seen are fa miliar North American warblers—espe cially palm, black-throated blue, prairie Cape May, black-and-white, redstart and common yellow-throats. We ident fied as many as fourteen species of wa blers in a single day (including the en demic Cuban Oriente warbler and th olive-capped warbler). Cuba, more tha 700 miles long, is the largest island in th West Indies and must be considered a ma jor wintering area essential to the long term survival of species with somewhat re stricted North American ranges, o habitats, such as the black-throated blue Cape May, and prairie warblers. Fortu nately, woodlands now occupy 12 percen more of Cuba than they did in the 1950

With the assistance of the district fo estry chief, Heriberto Ramirez, and h staff, especially Emilio Diaz and Rey naldo Balón, who were with us throughou our fieldwork, we proceeded to Mont Cristo, a forestry base, and beyond it, ove badly rutted, wet roads, eventually to Cu peyal, a fifty-five-square-mile nature re serve established in 1962. En route to Cu peyal we began to see and appreciate th

ffects of the wholesale logging that took ace between 1956 (when the area was sited by George R. Lamb, who pubshed a report on the ivorybill in Cuba) nd the 1959 revolution. Tracks that once erved as roads had been carved everyhere. Often they ran straight up and own hills and were rutted into ravines; ome had crevices ten feet deep. In addion, the clear-cutting of forests allowed unoff from frequent rains to wash away nuch topsoil. Thus, plantings of Cuban ines (*Pinus cubensis*) under the present overnment's reforestation program have ot grown as well as they might have—a actor possibly of crucial significance to he survival of the ivorybill. (Can the bird urvive until the trees are suitably mature o provide more extensive habitat?) Large reas of young, diversely aged plantings, ostered by foresters at many plantations, re mixed with a tangle of cutover hardvoods, junglelike in aspect.

We centered our search to the east and outh of the Cupeyal reserve in rough country with steep hills and rocky outcrops. Wetter slopes and lower areas near streams were covered either with second-growth deciduous forest and a dense understory or with head-high thickets of ferns and bushes. Drier slopes bore pine stands of various ages. We walked nine to twelve miles a day, despite frequent rain showers, searching for signs of the ivorybill. In particular we looked for big trees (of which there were few) and for the workings of the woodpecker, which feeds by scaling bark from freshly dead trees to obtain beetle larvae and other wood-boring insects. I chanced upon such workings near the Cupeyal House, in an area where the ivorybill had last been seen in 1976. At least three pine trees had been stripped of most of their bark within the previous few months, as evidenced by the fresh condition of the underlying wood and quite in contrast with the other gray, dead trees scattered about. Beneath the recently stripped trees were bits of fresh, white wood and pieces of bark two to six inches wide and four to eight inches long. These bits of evidence closely resembled the workings left by the pileated woodpecker, the continental North American species that at times scales bark like the ivorybill. There are no pileated woodpeckers in Cuba, and the other four resident woodpeckers (the Cuban green and West Indian red-bellied woodpeckers, and the two flickers, the northern and Fernandina's, all much smaller, weaker-billed woodpeckers) are incapable of stripping a tree in this way. Yellow-bellied sapsuckers from North America winter in Cuba, but they, too, are small and do not scale bark.

AMNH

The ivory-billed woodpecker, as depicted by pioneer American ornithologist Alexander Wilson

For four days in late February we sought the ivorybill in the area of pine workings, and in the surrounding mixed pinewoods, deciduous woods, and scrub, with no success. We concluded that a lone ivorybill had passed through the area sometime in the past half year, but that it was no longer in the vicinity.

Word of our search having passed

Neiman-Marcus

WONDERFUL THINGS

Just what you always wanted. Something from the Neiman-Marcus Christmas Book. Everyone does. It's the original, and still the finest. All the excitement of the world's markets packed into one beautiful catalog and brought right to your mailbox, so you can get a headstart on shopping, and conserve your time. Order your 1985 edition now for delivery in mid-October to your home or office.
$5.00.

Please send me my copy of the 1985 Neiman-Marcus Christmas Book for $5.00.

British airways

Mountain Travel presents "Quick Escape" #5 (5th in a series of 5)

AFRICA:
Climb Kilimanjaro!

$2850 INCLUDING
round trip airfare on British Airways from New York (based on GV10 fare, subject to change)

15-Day trips depart: 1986: *Jan 11, Mar 8, Jun 14, Aug 2, Oct 4, Dec 6*

- *6-day hike up Mt. Kilimanjaro, highest mountain in Africa*
- *A complete camp staff. Nothing to carry!*
- *3-day land-rover safari in Ngorongoro and Manyara game parks*
- *Hotel/lodges in Nairobi, Arusha and the parks.*

For more information and FREE 20-page, color brochure, call TOLL FREE (outside CA) at 800-227-2384. Within CA (415) 527-8100.

MOUNTAIN TRAVEL®
The Adventure Company

through the surrounding countryside, we found at our door one morning an old woodsman on a horse. He introduced himself as Felipe Montero Rodriguez, a longtime resident who, for some three decades, had been involved in forestry work in the region. He related the history of the ivorybill to us; namely, that it had been uncommon but present in the 1950s and had become increasingly rare in the 1960s and 1970s. Before December 1984, he had last seen one in 1977. On December 15 or 16, 1984, while walking in an area of fairly large, twenty-year-old pines, he had heard the pounding of a woodpecker on a tree. He described to us the bird that he observed for five minutes as *cao*-sized (the local crow, *Corvus nasicus*, which is ivorybill size), black and white, and crested, without red on the head (thus a female ivorybill). The site was some five miles south of us, and we moved our base to a working forestry nursery station at La Munición, near Sr. Montero's site of observation, a hill overlooking a steep, well-wooded valley. We reached the site nearly at dark on March 1, 1985. Here we heard the calls of a stygian owl, an uncommon tropical American owl that is potentially large enough to prey on an ivorybill. But we found no signs of the woodpecker that night or on the ensuing three days—all that were left to us before we had to return to Havana. On the morning of March 2, we did, however, discover a nest of the rare, endemic Gundlach's hawk, a bird-eating hawk related to, but larger than, the Cooper's hawk of North America. George Reynard heard the screechy calls, taped them, and found the nest of the hawk in a tall pine tree (the nest of a Gundlach's hawk had never been photographed nor the eggs and nest adequately described). We worried about finding the owl and pair of large hawks within 150 feet of where Sr. Montero had reported the ivorybill. We again concluded that no ivorybill was currently in that area.

Back in Havana on March 7 and 8, we discussed the situation with Cuban authorities and particularly with Dr. Garrido, just back from a meeting in Peru. Garrido is convinced that wilder, almost inaccessible land east and southeast of where we had worked will prove to have pockets of pines and other trees, of greater breadth and height than those we had observed, that could harbor ivorybills. Indeed, a pair had been reported in an isolated valley southeast of the Sierra de Moa, during the late 1970s. This information, along with our finding and Montero's report, convinced me that at least several lone ivorybills, and quite likely a few pairs, exist in the region between Cupeyal, the southern Sierra de Moa, and the Sierra de Purial to the southeast.

When I arrived back in New York, I submitted to my Cuban colleagues a plan for aircraft and ground searches by teams of forestry and ornithology specialists to locate areas of suitable or potentially suitable ivorybill habitat, if not the birds themselves. If these searches are carried out, I hope to return to Cuba in April 1986 (when all ivorybills ought to be paired and nesting or, if solitary, presumably located in suitable nesting habitat), either to help find the birds or to study them if they are located before then. A letter from Sr. Alayón in May stated that my plan was indeed being implemented; a team is going to La Melba this summer. I am convinced that only in Cuba is there any chance of the continued existence and possible buildup of a viable population of the ivorybill, a magnificent woodpecker that surely is one of the most endangered species of birds in the world. Given today's political climate it is ironic to think that, just possibly, Cuba and the United States may someday cooperate in the reintroduction of the ivorybill to North America!

Lester L. Short is chairman of the American Museum's Ornithology Department.

Oriental Passage

April 4 to May 7, 198

Relax on the Museum's exclusively chartered cruise vessel, *Illiria*. This small gem of a ship offers pampered service, superb food, and luxurious surroundings. Each excursion on land is designed to provide a rich and diversified experience of the history, art and culture of the ancient world. And the trip offers leisure to enjoy swimming, strolling, shopping or simply relaxing.

Halley's Comet, together with a lecture team, itinerary and cruise vessel that cannot be duplicated...call or write the Museum's Discovery Tours office for detailed information.

At the American Museum

The Dream Is Alive

The Dream Is Alive is now being shown on the giant, four-story screen of the Museum's Naturemax Theater. This new, large-format film about the space shuttle features breathtaking views from space filmed aboard the spacecraft. The astronauts, who say the views of the earth and moon in the film are the "closest thing to being there," carried the special, eighty-pound camera with them on several shuttle flights. The camera uses film that is ten times larger than 35-mm film and three times larger than the 70-mm film used by commercial film producers. The result is a huge image whose clarity and brilliance are not achievable with a normal system. The viewer will see the astronauts at work, both inside and outside the spacecraft, as they deploy satellites, capture and repair the malfunctioning "Solar Max" satellite, and walk in space. There are even scenes of the astronauts floating in their sleeping bags. For schedule information call (212) 496-0900.

Threshold Company

The Dream Is Alive *is the newest feature at the Museum's Naturemax Theater.*

At the Hayden Planetarium

The Hayden's new, double-feature Sky Show will continue throughout the summer and fall. *Hayden: The Golden Years* explores the astronomical discoveries of the last fifty years, and *Halley's Comet: Once in a Lifetime* demonstrates where and when people can expect to see Halley's comet. For information and show times call (212) 873-8828.

Delightful Animals

The family members' program in August will be *Delightful Animals,* two films for all ages. They are *Squirrel on My Shoulder,* about a naturalist who finds a baby squirrel, which is adopted and raised by his cat, and *The Mouse's Tale,* about the life and habits of dormice in Wiltshire, England. The program will take place on Tuesday, August 13, at 11:00 A.M. in the Kaufmann Theater, and again at 7:30 P.M. in the Auditorium. It is free and only open to members; for more information, call (212) 873-1327.

Songs of the Sea

On Tuesday, August 6, at 7:30 P.M., the Membership Office will present *Songs of the Sea,* a free concert by Tom Goux and Jacek Sulanowski, who have spent the last decade researching chanteys and ballads from the heyday of the great sailing ships. The program is open only to members; advance registration is required. For information call (212) 873-1327.

ingapore to Athens By Sea

Crayfish (p. 32)

Paul Colinvaux's *Why Big Animals Are Rare* (Princeton: Princeton University Press, 1978), a cogent introduction to the basic concepts of ecology, has been praised as "an incisive and stirring book, and a model of scientific explanation" by the *New Yorker.* The book's subjects include the social lives of plants, why the sea is blue, the ocean ecosystem, the succession affair, what hunting animals do, and why there are so many species. British zoologist Charles Elton wrote many of the classic texts on animal ecology, including *The Ecology of Invasions by Animals and Plants.* Originally published in 1958, it was reprinted by Chapman and Hall in 1972 and is available in paperback. For a good introduction to the characteristics of freshwater ecosystems and the animals that dwell in them, see *Ecology of Fresh Waters,* by Brian Moss (New York: John Wiley and Sons, 1980). T.H. Huxley's *The Crayfish,* published in 1880, was reprinted by the M.I.T. Press, Cambridge, in 1974.

Yoyogi Park (p. 48)

Ian Buruma's *Behind the Mask* (New York: Pantheon Books, 1984) is a fascinating examination of Japan's popular media (films, television, plays, books, comics), traditional literature, myths, and other elements—such as sexual demons, sacred mothers, transvestites, gangsters, drifters, and cultural heroes—that shape the Japanese collective imagination and national identity. He finds that sexuality and sex roles underpin the elaborate structures of Japanese culture, and that "violent entertainment and grotesque erotica are . . . important outlets in . . . an oppressive social system." In "Japan's Outrageous Conformists" (*Asia,* July-August 1982, pp. 16–20, 54–55), Buruma shows how the rebellious behavior of the Bamboo Shoots and other supposedly nonconformist youth tribes is actually "an elaborate fake, a beautifully studied act, that only looks like the real thing." *Japanese Culture and Behavior,* edited by Takie Sugiyama Lebra and William P. Lebra (Honolulu: University of Hawaii Press, 1974), contains many fine articles, such as "Higaisha-Ishiki: The Psychology of Revolting Youth in Japan," by Takeo Doi, "Delinquent Groups and Organized Crime," by Hiroaki Iwai, "Intergenerational Continuity and Discontinuity in Moral Values among Japanese," by Takie Sugiyama Lebra, and "Japanese Value Orientations and Culture Change," by William Caudill and Harry A. Scarr. Robert C. Christopher links the "highly conformist display of nonconformity" that takes place at Yoyogi Park to the pressures of the country's grueling educational system in *The Japanese Mind* (New York: Simon and Schuster, 1983), a perceptive and entertaining book that he describes as "a psychic and institutional guidebook to today's Japan." Social anthropologist Chie Nakane presents the important element of Japanese behavior and culture, including the emphasis on group organization, in *Japanese Society* (Los Angeles: University of California Press, 1972). Edwin O. Reischauer, who grew up in Japan and was the ambassador to that country under the Kennedy administration, is one of America's most respected Japanologists. *The Japanese* (Cambridge: Harvard University Press, 1977), his overview of Japanese history, culture, character, and psychology, is a standard introduction to Japanese civilization. Finally, Max Gluckman's "Rituals of Rebellion in South-East Africa" can be found in *Order and Rebellion in Tribal Africa* (New York: The Free Press, 1963).

Paul Chesley

Yoyogi Park, Tokyo

Phalaropes (p. 58)

O. Hildén and S. Vuolanto's "Breeding Biology of the Red-necked Phalarope *Phalaropus lobatus* in Finland" (*Ornis Fennica,* vol. 49, pp. 57–85) is by far the most detailed article written on these birds. E.O. Hohn explores their reproductive strategies in "Observations on the Breeding Behaviour of Grey- and Red-necked Phalaropes" (*Ibis,* vol. 113, pp. 335–48) and the hormonal basis of their behavior in "The Phalarope" (*Scientific American,* vol. 220, pp. 104–11). For a review of "unusual" mating systems in birds, including so-called role reversal, see W.J. Erckmann's "The Evolution of Polyandry in Shorebirds: An Evaluation of Hypotheses" in *Social Behavior of Female Vertebrates,* edited by S.K. Wasser (New York: Academic Press, 1983), and Lewis W. Oring's "Avian Polyandry: A Review," in *Current Ornithology, Vol. 3,* edited by R.F. Johnston (New York: Plenum Press, due out later this year). A detailed and accurate description of the phalarope's life history, drawn from other works, is presented in *The Birds of the Western Palearctic, Vol. 3,* edited by S. Cramp and K. Simmons (Oxford: Oxford University Press, 1983).

Rita Campo

Correction On page 92 of the May 198 *Natural History,* a caption incorrectly refers to the plant in the photograph as a coconut. It is in fact a taro, perhaps the coco yam, *Colocasia esculenta,* or the swamp taro, *Cyrtosperma chamissonis.*

American Airlines presents . . .

AAloha condo

All-Suite HAWAII

Enjoy the best of both worlds . . . the value of a condo and the services of a hotel . . . with the AAloha Condo tour package.

Fly American Airlines in wide body comfort to your own Hawaiian condominium. Altogether you can choose from 14 resorts where every room is a studio, 1, 2 or even 3-bedroom suite. All are managed by Hawaii's leader, Hotel Corporation of the Pacific.

And, all offer the services of a fine resort . . . like daily maid service, swimming pools, jet spas and complimentary parties. Most have restaurants and tennis is always free. Plus, you get the convenience and value of a complete kitchen.

Prices begin at only $16 per person* for four including an Avis rental car with ***unlimited free*** mileage. Best of all, you qualify for these low rates even when you fly on American Airlines' lowest fares.

* Land rates only, based on 4 persons, 2 night minimum stay.

See your travel agent or call American Airlines toll free

Hot Stuff

Why has it taken half a millennium for chilies to take hold in Anglo-Saxon cultures?

by Raymond Sokolov

As you may recall from last month's outing, I have lately been concocting flavored vodkas in the Russian manner, especially pepper vodkas made fiery and flavorful by hot peppers of the genus *Capsicum* (chilies). One of the less frequently noted virtues of these sophisticated folk spirits is that they promote reflection. After their alcoholic content has induced a certain calmness, you find yourself ruminating on other aspects of these remarkable beverages besides their ability to intoxicate.

Last month I considered the paradox that pepper vodka must be served ice cold in order to taste ideally hot. This happens, it turns out, because cold slows down the release of vodka's other volatile elements more completely than it impedes the escape of the flavoring elements in the chilies and other spices that Russians typically add.

An even more fundamental question lies behind the unrecorded discovery of this phenomenon by some experimental Russian toper long ago. He could not have done what he did if he had not had access to capsicums in the first place.

The story of the transmission of these warm-weather American exotics to the landlocked icebox of Europe begins in 1492 with Columbus. You will find a detailed and scholarly account of it in Jean Andrews's new book, *Peppers: The Domesticated Capsicums* (University of Texas Press). Andrews, who has devoted many years to the study, culture, and painting of capsicums, dates the arrival of the chili in Europe to the arrival of the *Pinta* at Bayona, Spain, in 1493, an event celebrated locally on March 1. Whether Columbus actually brought chilies back with him from this first voyage is unknown. He definitely knew about ther for in his first letter to Ferdinand and Is bella and the treasurer of Aragon, wrote that the West Indian islanders e dured the cold of winter in their mou tains "with the aid of the meat they e with very hot spices."

On the assumption that Columbus to the obvious step of collecting the source these spices, Andrews made a pilgrima to Bayona in 1983 and scattered jalape seeds in the churchyard of Ex-Colegia Santa María in Bayona, where the *Pinta* crew gave thanks for their safe return most five centuries ago.

Written accounts of the chili appear after Columbus's second voyage (one m even have been written in April 149 And since a major impulse for these a later voyages of exploration was to bri exotic spices to Europe, it is not surprisi that this new "pepper" (it is entirely un lated to the black pepper, *Piper nigru* which Columbus hoped to find) w quickly spread from one end of the Spa ish and Portuguese trade routes to t other.

You might guess that with their cap cum commerce in full swing by the mid 1500s, the Iberian traders would ha been the source for the chilies that start turning up in the Slavic countries abo the same time. But this is not how it ha pened. The Portuguese did bring cap cums to India and China, through th colonies at Goa and Macao, making p sible hot Indian and Sichuan food as know it. But the first red capsicums to ter northern Europe came from the B kans, imported by the Ottoman Tur Andrews speculates that the Ottoma had latched on to chilies as early as 15 during their siege of the Portuguese c

y at Hormuz in the Persian Gulf. From
e Balkan fringe of the Ottoman Empire,
e peppers spread naturally into neigh-
ring spheres of influence, to the Ger-
an-speaking part of the Holy Roman
npire (1543) and to the vast territories
the former Byzantine Empire and to
ussia. Hungarians, in the middle of this
tteleuropäisch pepper pot, started talk-
g about paprika as early as 1569. The
agyar word *paprika* is a variation on a
avic term for pepper, *peperke, piperke,*
paparka.

Hungary was and still is the northern-
ost major producer of capsicum peppers
Europe. No doubt it is at the upper limit
the plant's range. But even Hungary
s slow to work paprika into its everyday
isine (the rest of northern Europe never
similated truly hot spices). The first two
ungarian paprika recipes did not appear
print until 1829, in Istvan Czifrai's
okbook. They were paprikas chicken
d halaszle, the fish soup of Szeged, the
nter of capsicum culture in Hungary
en and now.

When I first met George Lang in 1971,
the eve of the publication of his *The*
isine of Hungary, he served me ha-
zle (see recipe), a robust soup and an el-
ant allusion to the history of Hungarian
oking.

For Hungarians, paprika is not the
nocuous red dust we buy in supermar-
ts; it comes in several grades, from the
eet to the fiery hot. But paprika con-
isseurship is limited to ethnic Magyars
d food hobbyists, just as almost all en-
usiasm for hot capsicums used to be a
ry special predilection in this country
tside of Louisiana and regions formerly
lonized by Spain or Mexico.

In those places, there has always

100% Merino Wool Mattress Pad

MANUFACTURER DIRECT

Soft 100% Merino Wool cushions and cradles your body for a deeper, more restful night's sleep. Even the best mattress creates pressure points on the shoulders, hips and back. Soft, thick Merino Wool conforms to the contours of your body, relieving pressure points. Many people report they fall asleep faster and enjoy a more restful sleep.

In an independent study of our wool pad conducted by the University of Wisconsin; 83% of the participants reported a better night's sleep, 94% stated their muscles and joints felt better the next day.

Wool is a natural insulator. In winter, the pad retains body heat to keep you warm. In summer, the pad keeps you cool by absorbing moisture and carrying it away from your body. As a new innovation, we have eliminated the elastic straps and have designed the pad like a fitted bottom sheet. Machine Washable. Non-Allergenic.

If you don't enjoy the best night's sleep you've ever had, simply return the pad for a complete refund.
Delivery: We ship within 24 to 48 hrs.

Painting of Capsicum chinense *var.* rocotillo, *by Jean Andrews*

been a cult of hot peppers and hot food, but the supermacho aspects of Tex-Mex food, with its jalapeño-eating contests and four-alarm chili, confused outsiders and made them think that chilies were a crude and unreasonable condiment unrelated to the usual culinary refinements: flavor and complexity.

The same confusion muddled American appreciation of Indian food and, most recently, Sichuanese and Hunanese. Some people insisted on very hot and presumably authentic versions of these exotic cuisines. Others, unused to hot foods, sent back what they had ordered, creating difficulties and embarrassment in restaurant kitchens. Meanwhile the judgment, enjoyment, and presentation of Mexican, Indian, and Chinese food in this country was polarized into an oversimplified matter of hot or cold.

Vast inexperience of capsicums l most Americans unable to approach the new foods with an open mind. It has tak almost twenty years for the initial shock hot capsicum-based cuisines to wear and for large numbers of people to beg to get beyond the crude fact of hotness an appreciation of the diverse flavo brought to food by the many varieties chilies employed with such finesse el where.

The restaurant booms in Mexica Sichuan, and Thai food have helpe More and more people have habituat their palates to the burn of capsaicin, t chemical essence of capsicum heat. Th are now ready to pay attention to the m tiform pleasures of the myriad cultivars *Capsicum annuum*, the chili species sponsible for almost all the peppers we counter.

And we do encounter an ever greater mber, even those of us far from Santa and El Paso and the Grand Central arket in Los Angeles. There has been a eat change since I first read the section chilies in Diana Kennedy's *The Cui-es of Mexico* and wondered if I would er be able to cook most of the dishes in r book at home, since they required ar-ne chilies with names like *pasilla* and ero and *cascabel.*

I also wondered if the lady wasn't mak-g a bit of a learned fuss over chili speci-ity. Then I took a trip to the French is-nds of the Caribbean and immersed yself in the local Creole cuisine, which, nong other fetching characteristics, has ypical flavor that owes much to a crin-y, cherry-sized pepper, hot but not infer-lly so. It was crucial to the taste of the nnipresent fish stew called blaff and to any other dishes impossible to re-create home without it.

Now I can buy this pepper by the bag in y supermarket. And thanks to Jean An-ews, I can identify it. It is *C. chinense,* r. *rocotillo.* And I am happy to say that ndrews likes it too.

"After growing and tasting peppers om all over the Western Hemisphere for ve years," she writes, "my hands-down vorite 'eating pepper' is the rocotillo. his crisp textured fruit with enough pun-ency to be interesting but never caustic is t only delicious eaten raw but also beau-ful to look at when used as a garnish." *ocotillos* are either pale yellow-green or d, and they grow well in central Texas. at them on the side, as a condiment with eans or roast meat, or throw them in with l manner of foods while they cook. The *rocotillos* I am buying are pallid in flavor compared to the ones I recall from Martinique, but they are interesting and worth tasting anyway.

That we can buy *rocotillos* at all in New York is wonderful testimony to the resilience of the marketplace and to the flexibility of the consumer. But at the same time we might also ask ourselves why it has taken half a millennium for chilies to take serious hold in a culture with an Anglo-Saxon, north European base.

Why did capsicums not find a happy home north of the Pyrenees? To an extent, botany was destiny. Peppers were hard to grow in northern climates. But the Hungarian experience is proof that it can be done if the will is there.

The taste for extremely hot spices, of which capsicums are the epitome, does seem to be culturally acquired. Sichuan province already had embraced its local brown pepper before capsicums came in, and India was a proverbial center of spices. Northern Europe, on the other hand, had to import most of its spices. And capsicums seem to have presented too much of a challenge to the palate. They did not really catch on with English speakers until the current craze for regionalisms and ethnic food swept over the previously phlegmatic northern United States.

Is this a good thing? Certainly it opens new possibilities at the table. And if your tongue is burning from some new variety of hot pepper, try to remember that capsicums are an excellent source of vitamin C.

Raymond Sokolov is a writer whose special interest is the history and preparation of food.

Halaszle

(Hungarian Fisherman's Broth,
from George Lang's *The Cuisine of Hungary,* Atheneum)

1 whole live carp, 5 to 6 pounds, or a section of similar weight
Salt
3 or 4 medium-sized onions (about 1 pound), chopped fine
2 tablespoons paprika
1 green pepper, cut across in very thin slices

1. Carp should be alive when you buy it. Ask the fishmonger to bone carp, remove its skin, and cut meat in 4- or 5-inch chunks. Be sure he gives you the skin and bones. Also, make sure you purchase female carp with a lot of roe; purchase extra milt. If you buy a male fish with milt, purchase extra roe. Do not wash the inside of the fish; the blood makes the dish tasty.
2. Boil skin, bones, and head of the carp in 2 quarts water with 1 teaspoon salt for about 20 minutes. Strain the broth.
3. Cook the onions in the fish broth for about 30 minutes. Force the onions through a sieve or purée in a blender and put back in the broth.
4. In a 4-quart soup or stew kettle, place pieces of fish next to each other. Pour the onion broth over the fish. Add as much water as necessary to cover fish.
5. Bring liquid to a boil; add 1 teaspoon salt, the paprika, and green pepper. Cook for about 10 minutes. Do not stir, but shake the pot.
6. Add the roe and milt and cook for an additional 4 or 5 minutes. Let the soup stand for 5 minutes before serving.
7. Serve as a one-dish luncheon, as a late-night supper dish, or as the soup and fish courses of a dinner.

Yield: 8 to 10 servings

A Nasty Habit of Spitting

South Africa has a number of reptile parks and one of the largest of these is Transvaal Snake Park, outside Johannesburg. Tony Bannister has visited there often in the past year and a half to take photographs for a book on African reptiles and that is how he came to take this photograph of a Mozambique spitting cobra (*Naja mossambica*).

According to the late Vivian FitzSimons, an authority on the snakes of southern Africa, this species—also known as *m'Fesi*—is one of the most dangerous on the continent. It is high-strung and is one of only a few snakes in Africa that can "spit" its venom.

If the snake perceives any threat, it will rear up as much as two thirds of its length and spit two streams of venom that can travel up to nine feet. Actually the snake squirts, rather than spits, the venom by contracting muscles that surround its poison gland. This forces the poison into a duct, according to FitzSimons, and then out through openings near the tips of the fangs. The cobra usually directs its attack toward the face or eyes of its adversary. If the venom enters the eyes, it can cause intense pain and temporary or permanent blindness.

But the Mozambique spitting cobra is not an aggressive snake and usually uses its poison as a defensive tactic. Like one other African snake, the rinkals, it often feigns death rather than attempting to bite. This cobra generally eats small mammals, birds, amphibians, lizards, and bird eggs.

The snake in this photograph would ordinarily have sprayed Bannister, but the naturalist-photographer brought a friend along with him as a decoy. The friend distracted the cobra and promptly got soaked. Bannister, who kept his left eye closed and his right eye on the camera's viewfinder, stayed mostly dry but took a few direct hits on the lens.

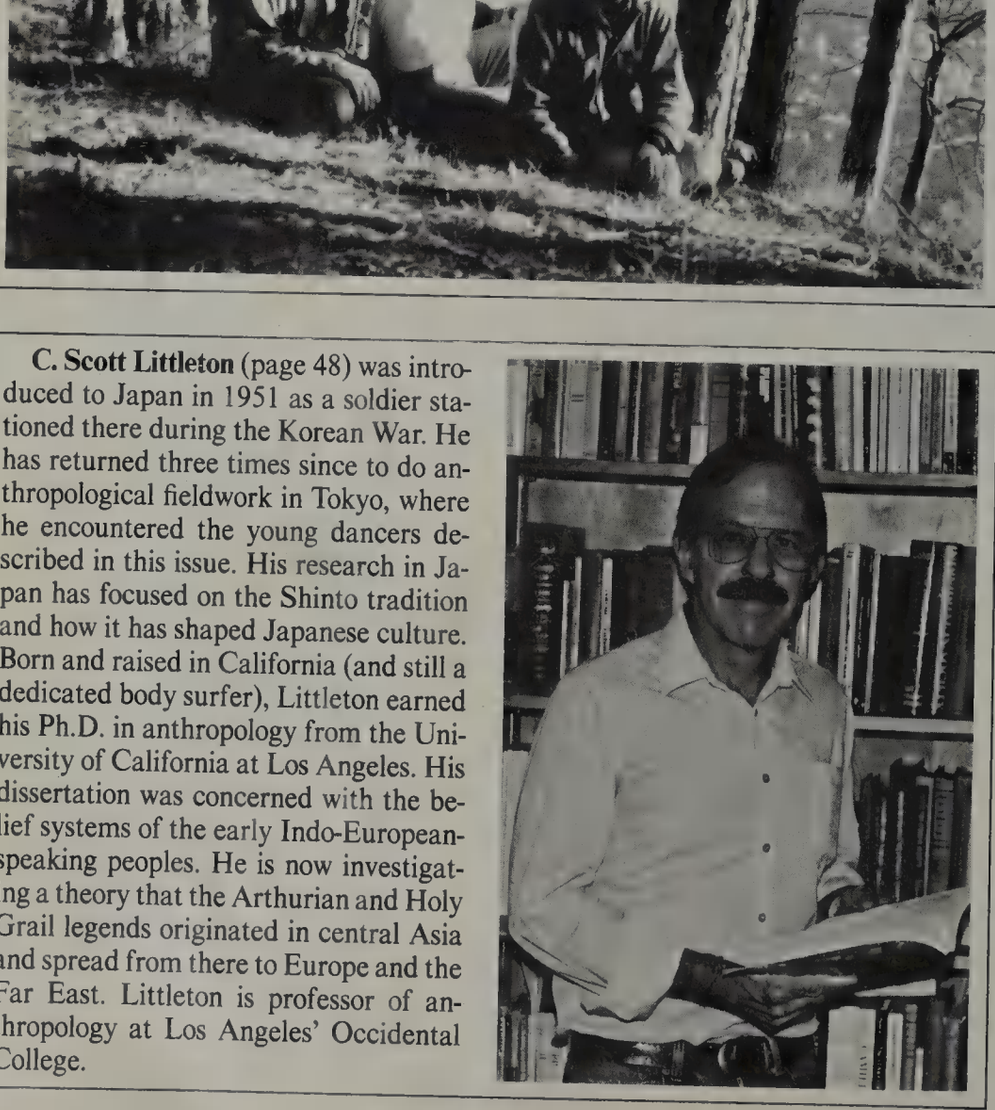
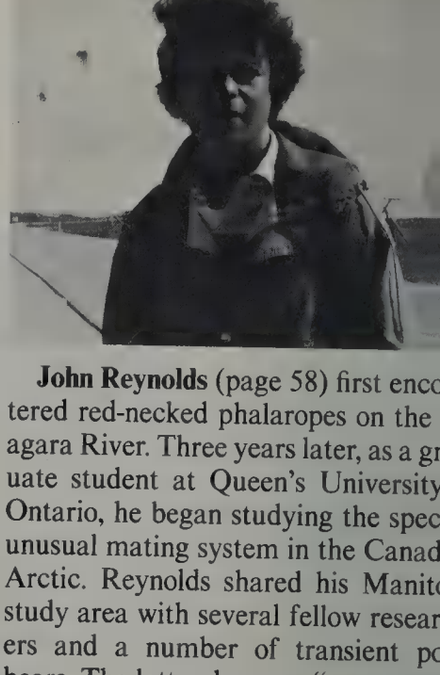
David M. Lodge (page 32) received his doctorate in zoology from Oxford University as a Rhodes scholar. "From England," says Lodge (middle), "I was looking for a way to expand my ecological horizons and place my studies of snail populations in the broader perspectives of the ecology of communities." His research at the University of Wisconsin at Madison Center for Limnology allows him to do just that. He dives into lakes to investigate predation and herbivory and their impact on lake ecosystems. Lodge recently took up duties as an assistant professor at the University of Notre Dame. Coauthor **Annamarie L. Beckel** (left), an ecologist and writer, earned her doctoral degree in ecology and behavioral biology at the University of Minnesota. She has carried out field studies of river and sea otters and heads a pine marten captive breeding and reintroduction program. Beckel has also done her share of crayfish trapping and is now writing a book covering the hundred-year history of limnology studies at the University of Wisconsin. **John J. Magnuson** (right), a veteran fisheries biologist with an extensive background in teaching and research, has helped train many young ecologists. He is professor of zoology at the University of Wisconsin at Madison and director of the Center for Limnology. Magnuson guides many of the long-term investigations undertaken by the Center, in particular, those concerning his area of greatest expertise—fishes. When not delving into lake life, he enjoys gardening, photography, and collecting fish stamps.





John Reynolds (page 58) first enco
tered red-necked phalaropes on the
agara River. Three years later, as a gr
uate student at Queen's University
Ontario, he began studying the spec
unusual mating system in the Canad
Arctic. Reynolds shared his Manit
study area with several fellow resear
ers and a number of transient po
bears. The latter, he says, "were usua
indifferent to us but would sometim
amble over to see what the funny a
mals with binoculars and mist nets w
doing (we were beating an unequivo
retreat!)." Reynolds, currently a visit
researcher at the Boreal Institute

ecology and growth of young phalarop
During May and June of this year,
was in central Finland studying ruffs a
other shorebird species.

C. Scott Littleton (page 48) was introduced to Japan in 1951 as a soldier stationed there during the Korean War. He has returned three times since to do anthropological fieldwork in Tokyo, where he encountered the young dancers described in this issue. His research in Japan has focused on the Shinto tradition and how it has shaped Japanese culture. Born and raised in California (and still a dedicated body surfer), Littleton earned his Ph.D. in anthropology from the University of California at Los Angeles. His dissertation was concerned with the belief systems of the early Indo-European-speaking peoples. He is now investigating a theory that the Arthurian and Holy Grail legends originated in central Asia and spread from there to Europe and the Far East. Littleton is professor of anthropology at Los Angeles' Occidental College.

Anthony Bannister (page 78), who w

How dare The Glenlivet be so expensive?

How dare we place such a premium on our 12-year-old Scotch? The same reason great vintage wines and fine champagne cognacs are so expensive. Taste. Just one sip and you'll know that The Glenlivet has a taste that's decidedly superior.

The Glenlivet is Scotland's first and finest single malt Scotch. And, just as it always has been, this 100% Highland malt whisky is distilled from natural spring water and fine malt barley, then aged in oaken casks.

Only The Glenlivet's time-honored methods can achieve this unequaled taste. A taste that sets us apart. Its smoothness, body and bouquet are qualities found only in this unique Scotch.

Of course you may elect to purchase a good Scotch that's less expensive. But for a truly superior taste, you'll have to pay us the greater price.

The Glenlivet

12-year-old unblended Scotch.
About $20 the bottle.

Bligh's Bounty

A captain who followed the rules meticulously found an animal that broke them brilliantly

by Stephen Jay Gould

In 1789, a British naval officer discovered some islands near Australia and lamented his inability to provide a good description:

> Being constantly wet, it was with the utmost difficulty I could open a book to write, and I am sensible that what I have done can only serve to point out where these lands are to be found again, and give the idea of their extent.

As he wrote these lines, Capt. William Bligh was steering a longboat with eighteen loyal crew members into the annals of human heroism at sea—via his 4,000-mile journey to Timor, accomplished without loss of a single man, and following the seizure of his ship, *The Bounty,* in history's most famous mutiny.

Bligh may have been overbearing; he surely wins no awards for insight into human psychology. But history and Charles Laughton have not treated him fairly either. Bligh was committed, meticulous, and orderly to a fault—how else, in such peril, could he have bothered to describe some scattered pieces of new Pacific real estate.

Bligh's habit of close recording yielded other benefits, including one forgotten item to science. Obsessed by the failure of his *Bounty* mission to bring Tahitian breadfruit as food for West Indian slaves, Bligh returned to Tahiti aboard the *Providence* and successfully unloaded 1,200 trees at Port Royal, Jamaica, in 1793 (his ship was described as a floating forest). En route, he stopped in Australia and had an interesting meal.

George Tobin, one of Bligh's officers, described their quarry as

> a kind of sloth about the size of a roasting pig with a proboscis 2 or 3 inches in length. . . . On the back were short quills like those of the Porcupine. . . . The animal was roasted and found of a delicate flavor.

Bligh himself made a drawing of his creature before the banquet. The officers of the *Providence* had eaten an echidna, one of Australia's most unusual mammals—an egg-laying anteater closely related to the duck-billed platypus.

Bligh brought his drawing back to England. In 1802, it appeared as a plate (reproduced here) accompanying the first technical description of the echidna's anatomy by Everard Home in the *Phil sophical Transactions of the Royal So ety* (G. Shaw had published a prelimina and superficial description in 1792).

Home discovered the strange mix reptilian and mammalian features th has inspired interest and puzzleme among biologists ever since. He also i posed upon the echidna, for the first tim the distinctive burden of primitivity th has continually hampered proper zoolo cal understanding of all monotremes, t egg-laying mammals of Australia. Hon

Halleyscope®

described the echidna as not quite all there in mammalian terms, a lesser form stamped with features of lower groups:

> These characters distinguish [the echidna] in a very remarkable manner, from all other quadrupeds, giving this new tribe a resemblance in some respects to birds, in others to the Amphibia; so that it may be considered as an intermediate link between the classes of Mammalia, Aves, and Amphibia.

Unfortunately, Home could not study the organ that most clearly belies the myth of primitivity. "The brain," he wrote, "was not in a state to admit of particular examination." Home did have an opportunity to infer the echidna's anomalously large brain from the internal form of its skull, well drawn on the plate just preceding Bligh's figure (and also reproduced here). But Home said nothing about this potential challenge to his general interpretation.

And so the burden of primitivity stuck tenaciously to echidnas, and continues to hold fast in our supposedly more sophisticated age. Some great zoologists have struggled against this convenient fallacy, most notably the early French evolutionist Etienne Geoffroy Saint-Hilaire, who coined the name *Monotremata* (see last month's column) and labored unsuccessfully to establish the echidna and platypus as a new class of vertebrates, separate from both mammals and reptiles and not merely inferior to placentals. By his own manifesto, he chose his strategy explicitly to avoid the conceptual lock that assumptions of primitivity would clamp upon our understanding of monotremes. He wrote in 1827:

> What is defective, I repeat, is our manner of perception, our way of conceiving the organization of monotremes; that is, our determination, made a priori, to join them violently to mammals [by *violemment,* Geoffroy means, of course, "without any conceptual justification"], to place them in the same class and, after our disappointments and false judgments, then to make our unjust grievances heard, as when we speak of them as mammals essentially and necessarily outside the rules.

But Geoffroy's legitimate complaint, so eloquently expressed, did not prevail, and the myth of primitivity continues, despite its blatant flaw. As I argued in last month's column on platypuses, the myth of primitivity rests upon a logical confusion between early branching from the ancestors of placental mammals (the true meaning of reptilian characters retained by monotremes) and structural inferiority. Unless geological age of branching is a sure guide to level of anatomical organization—as it is not—egg laying and interclavicle bones do not brand platypuses and echidnas as inferior mammals.

Beyond this general defense, echidnas can provide ample specific evidence of their adequacy. They are, first of all, a clear success in ecological terms. Echidnas live all over the Australian continent (and extend into Papua-New Guinea), the only native mammal with such a wide range. Moreover, *the* echidna, as a single struggling relict, ranks with *the* rat and *the* monkey (those meaningless synecdoches of the psychological literature) as an absurd abstraction of nature's richness. Echidnas come as two species in two separate genera and with quite different habits. *Tachyglossus aculeatus* (the Australian form with Papuan extensions) rips apart ant and termite nests with its stout forelimbs and collects the inhabitants on its sticky tongue. The larger and longer-snouted *Zaglossus bruijni* of Papua-New Guinea lives on a nearly exclusive diet of earthworms. Moreover, three other species, including the "giant" echidna, *Zaglossus hacketti,* have been found as fossils in Australia. Echidnas are a successful and at least modestly varied group.

But echidnas hold a far more important ace in the hole as their ultimate defense against charges of primitivity. The same cultural biases that lead us to classify creatures as primitive or advanced have established the form and function of brains as our primary criterion of ranking. Echidnas have big and richly convoluted brains. Scientists have recognized this anomaly in the tale of primitivity for more than a century—and they have developed an array of arguments, indeed a set of traditions, for working around such an evident and disconcerting fact. Large brains undoubtedly serve echidnas well; but they also help to instruct us about an important issue in the practice of science—how do scientists treat factual anomalies? What do we do with evidence that challenges a comfortable view of nature's order?

The echidna's brain refutes the myth of primitivity with a double whammy—size and conformation. (I discuss only the Au tralian species, *Tachyglossus aculeatu* its larger Papua-New Guinea relative, *Z glossus,* remains virtually unknown to sc ence—for basic information about echi nas, see the two books by M. Griffith *Echidnas,* Pergamon Press, 1968; ar *The Biology of Monotremes,* Academ Press, 1978.) Since mammalian brains i crease more slowly than body weig along the so-called mouse-to-elepha curve, we can use neither absolute nor re ative brain weight as a criterion. (B mammals have absolutely large brains an uninteresting consequence of body siz while small mammals have relative large brains because brains increase mo slowly than bodies.) Biologists have ther fore developed a standard criterion: me sured brain weight relative to expecte brain weight for an average mammal *the same* body size. This ratio, dubbed E (or encephalization quotient) in amusi analogy with you know what, measur 1.0 for mammals right on the mouse-to-e ephant curve, above 1.0 for brainier tha average mammals, and less than 1.0 f brain weights below the norm.

To provide some feel for the range EQ's, so-called basal insectivores—a s lected stem group among the order trac tionally ranked lowest among placent mammals—record a mean of 0.311. Ad ing advanced insectivores, the avera rises to 0.443. Rodents, a perfectly r spectable group (and dominant amo mammals by sheer number), display mean EQ of 0.652. (Primates and carn vores rank consistently above 1.0.) Mon tremes are not, by this criterion, mental g ants—their EQ's range from 0.50 0.75—but they rank way above the trac tional primitives among placentals ar right up there with rodents and other "r spected" groups. Monotremes continue shine by other standards of size as we Some neurologists regard the ratio brain to spinal cord as a promising me sure of mental advance. Fish generally d below 1:1 (spinal cord heavier than brain We top-heavy humans tip the scale

Skull of an echidna, from Philosophical Transactions of the Royal Society, 1802

THE MAGNIFICENT OBSESSION THAT PRODUCED THE COFFEE FAVORED BY KINGS.

Victor Th. Engwall

In 1853, in the small seaport of Gävle, Sweden, Victor Th. Engwall was seized by an obsession . . . to produce the perfect coffee. He started the company that still bears his name and began a tradition so enduring it has brought Gevalia® Kaffe the Royal Seal of approval from generations of Sweden's Kings.

When you first taste Gevalia Kaffe, you may feel almost a sense of recognition . . . a *déjà vu*. Not that it's likely you've ever tasted coffee this good before. But this is the way you've always wanted coffee to taste. Rich. Full-bodied, without bitterness. As good in the cup as fine coffee smells at the moment of grinding. Many ask what gives this superb coffee its high flavor notes, lively piquancy, delicate nuances. There is no simple answer and little purpose in trying to fathom why Gevalia is so agreeable. It is enough just to enjoy Sweden's most beloved coffee in your home and share it with friends.

COMES WHOLE BEAN OR GROUND, REGULAR OR DECAFFEINATED.

Gevalia Kaffe is a whole bean coffee which we will grind for you if you prefer. You may order Gevalia regular or decaffeinated by a patented European process. This special process applies the same substance that creates the effervescence in sparkling water to the coffee beans at a certain temperature and pressure. This draws out caffeine, while the full coffee flavor and richness remain. After roasting, Gevalia is quickly vacuum sealed in golden foil pouches. To preserve freshness, it comes only in the half-pound size.

TRY GEVALIA THROUGH A SPECIAL IMPORT SERVICE.

Until recently, Gevalia Kaffe has never been exported to the U.S. It probably never will be sold here in the usual manner. The only way to obtain a trial supply is by ordering it directly from the Gevalia Kaffe Import Service.

THE REGAL GEVALIA CANISTER (VALUE $18.00) YOURS AS A GIFT.

To further assure that every ounce of Gevalia Kaffe is kept at its best until consumed, a special canister has been designed. Of porcelain-glazed white ceramic, this imported canister is embossed in gold with the Royal Crest of Sweden. Its ingenious closure device locks in freshness by creating an air-tight seal.

With your trial supply of Gevalia Kaffe we will send you the Regal Gevalia Canister as a gift. It is yours to keep with our compliments, whether or not you decide to continue with the Service.

By Appointment to His Majesty the King of Sweden.

50:1; cats score 4:1. The "lowly" echidn waddles in front of tabby at approx mately 6:1.

By conformation, rather than simpl size alone, echidnas are even more impres sive. The neocortex, the putative site o higher mental functions, occupies a large percentage of total brain weight in suppos edly advanced creatures. The neocortex o basal insectivores averages 13 percent o brain weight; the North American marsu pial opossum records 22 percent. Echi nas score 43 percent (platypuses 48 pe cent), right up there with the prosimian (54 percent), basal group of the lordly pr mates. (All my figures for brain size come from H.J. Jerison's *Evolution of th Brain and Intelligence,* Academic Pres 1973, and P. Pirlot and J. Nelson, "Volu metric Analysis of Monotreme Brains, *Australian Zoologist,* vol. 20, 1978.)

The neocortex of echidnas is not onl expanded and nearly spherical as in pr mates; its surface is richly convoluted in series of deep folds and bumps (sulci an gyri), a traditional criterion of mental ad vance in mammals. (Curiously, by con parison, the platypus neocortex, whi equally expanded and spherical, is almo completely smooth.)

Many famous nineteenth-century neu roanatomists studied monotreme brain hoping to understand the basis of huma mental triumph by examining its lowly o igins. Echidnas provided an endless sourc of puzzlement and frustration. Willia Henry Flower dissected an echidna 1865 and wrote of "this most remarkab brain, with its largely developed an richly convoluted hemispheres." He ad mitted: "It is difficult to see in many of th peculiarities of their brain even an ap proach in the direction of that of the bird And Grafton Elliot Smith, the great Au tralian anatomist who later fell for Pil down in such a big way, wrote with evide befuddlement in 1902:

The most obtrusive feature of this brain the relatively enormous development of th cerebral hemispheres . . . . In addition, th extent of the cortex is very considerably i creased by numerous deep sulci. The mea ing of this large neopallium is quite incon prehensible. The factors which the study other mammalian brains has shown to the determinants of the extent of the cort fail completely to explain how it is that small animal of the lowliest status in th mammalian series comes to possess th large cortical apparatus.

One might have anticipated that scie tists, so enlightened by monotreme me tality, would simply abandon the myth primitivity. But prompt submission items of contrary evidence is not, despi

other prominent myth (this time about entific procedure), the usual response scientists to nature's assaults upon tra- tional beliefs. Instead, most students of onotreme brains have recorded their rprise and then sought different criteria, ain to affirm the myth of primitivity.

A favorite argument cites the absence monotremes (and marsupials as well) of corpus callosum—the bundle of fibers nnecting the right and left hemispheres "higher" mental processing in placental ammals. In a wonderful example of bla- ntly circular logic, A.A. Abbie, one of ustralia's finest natural historians, wrote a famous article of 1941 (commissures, a neuroanatomist, are connecting bands neural tissue, like the corpus callosum):

nce in mammals cerebral evolution and th it any progressive total evolution is re- cted so closely in the state of the cerebral mmissures it is clear that the taxonomic gnificance of these commissures far tran- ends that of any other physical character.

In other words, since we know (a priori) at monotremes are primitive, search for e character that affirms a lowly status ck of a corpus callosum) and proclaim is character, ipso facto, more important an any other (size of brain, convolutions, any other indication of monotreme ade- acy). (I shall have more to say about mmissures later on, but let me just men- on for now that lack of a corpus callosum es not preclude communication across e cerebral hemispheres. Monotremes ssess at least two other commissures— e hippocampal and the anterior—capa- e of making connections, though by a ute more circuitous than the pathway of e corpus callosum.)

This tradition of switching to another iterion continues in modern studies. In eir 1978 article on monotreme brain zes, for example, Pirlot and Nelson ad- it, after recording volumes and convolu- ons for echidnas: "It is very difficult to olate criteria that clearly establish the rimitiveness' of monotreme brains." But ey seek and putatively find, though they onorably temper their good cheer with t another admission of the puzzling size the monotreme neocortex:

his cortex could be considered to be hong the most primitive mammalian cor- es on the basis of the low number and low nsity of large, especially pyramidal neu- ns. It is surprising to find that a very high oportion of cortex is neocortex. This does t necessarily mean an advanced degree of ogressiveness, although the two are usu- y related.

The basic data on size and external con- rmation of echidna brains have been re-

Unlike other answering machines, the new Toshiba won't give you the silent treatment. It says nice things like "No message," or "Three messages. Monday 8:15 pm..." Only Swan Hellenic offers you...

THE LEARN BOAT™

Learn your way around on a 17 day or 29 day Mediterranean vacation with 5 guest lecturers.

22 VACATION VOYAGES VISIT 180 PLACES.

Each Swan Hellenic vacation combines places you know about with others you'll want to learn about.

These sites and settings are linked to ancient legends, myths and history. You can explore the remains of Greek, Roman, Byzantine, Ottoman and Islamic civilizations.

That's why Swan Hellenic takes along guest lecturers. They offer authoritative and relevant information on the empires you'll trace.

You'll learn so much listening to these experts, you don't need to be a historian or an archeologist to thoroughly enjoy this unique vacation.

You can see the Mediterranean from whole fleets of boring cruise ships. Or, you can learn your way around with Swan Hellenic.

corded (and viewed as troubling) for mo than a century. More sophisticated formation on neural fine structure and a tual use of the cortical apparatus in lear ing has been gathered during the pa twenty years—all affirming, again ar again, the respectability of echidna intel gence.

In 1964, R.A. Lende (*Journal of Ne rophysiology,* vol. 27) published the fi extensive map of localized sensory ar motor areas on the echidna's cerebral co tex. (I discussed the general procedures such study in August's column on plat pus brains. P. S. Ulinski has recently co firmed and greatly extended Lende's wo in a series of elegant experiments—*Jou nal of Comparative Neurology,* vol. 22 1984.) Lende discovered a surprising pa tern of localization, basically mammali in character but different from placent mappings. He identified separate are for visual, auditory, and sensory contr (the motor area overlapped the sensory r gion and extended forward to an adc tional section of the cortex), all dema cated one from the other by constant sul (fissures of the cortex) and located t gether at the rear of the cortex.

Most surprisingly, these areas abut or another without any so-called associati cortex in between. (Association cortex i cludes areas of the cerebral surface th do not control any specific sensory or m tor function and may play a role in coord nating and integrating the basic input For this reason, amount and position association cortex have sometimes bee advanced as criteria of "higher" ment function. But such negative definitions a troubling and should not be pushed t hard or far.) In any case, Lende identifie a relatively enormous area of unspecifie (perhaps association) cortex in front of h mapped sensory and motor areas. Lend concluded, in a statement oft-quote against those who maintain the myth primitivity:

Ahead of the posteriorly situated senso and motor areas established in this stu there is relatively more "frontal cortex than in any other mammal, including ma the function of which remains unexplaine

Other studies have tried to push th echidna brain to its practical limits by im posing upon these anteaters all the mo ern apparatus of mazes, levers, and foo rewards so favored by the science of com parative psychology. Echidnas have pe formed remarkably well in all these stu ies, again confuting the persistent im pression of stupidity still conveyed b textbooks and even by the most "officia of all sources—the Australian Museum

ɔmplete Book of Australian Mammals, ited by R. Strahan (Sydney: Angus and ɔbertson, 1983), which insists without idence:

this last respect [brainpower], mono-emes are inferior to typical placental ammals and, probably, to typical marsu-als. The paucity of living monotremes ay therefore be due to their being less ight, less adaptable in their behavior, an other mammals.

To cite just three studies among several similar intent and conclusion:

1. Saunders, Chen, and Pridmore (in *nimal Behavior,* 1971) ran echidnas rough a simple two-choice T-maze own a central channel, then either right left into a bin of food or a blank wall). ney trained echidnas to move in one di-ction (location of the chow, of course), en switched the food box to the other m of the T. In such studies of so-called bit-reversal learning, most fish never vitch, birds learn very slowly, mammals pidly. Echidnas showed quick improve-ent with a steady reduction in errors—d at typically mammalian rates. Half e experiments (seven of fifteen) on well-ained echidnas yielded the optimal per-rmance of "one-trial reversal" (you vitch the food box and the animal goes e wrong way—where the food used to —the first time, then immediately cot-ns on and heads in the other direction, ward the chow, each time). Rats often ow one-trial reversal learning, birds ver.

2. Buchmann and Rhodes (*Australian oologist,* 1978) tested echidnas for their bility to learn positional (right or left) d visual-tactile (black and rough versus hite and smooth) cues—with echidnas shing the appropriate lever to gain their od reward. As an obvious testimony to ental adequacy, they report that "unsuc-ssful (unrewarded) responses were often sociated with vigorous kicking at the beranda." Echidnas learned at a charac-ristic rate for placental mammals and so remembered well. One animal, re-sted a month later, performed immedi-e one-trial reversals.

Buchmann and Rhodes compared their chidnas with other animals tested in simi-r procedures. Crabs and goldfish did not ow improvement (did not learn) over me. Echidnas displayed great variation their speed of learning—one improved ster (and one slower) than rats and men-lly retarded humans: all echidnas per-rmed better than cats. Take these re-lts (not to mention the reward for ccess) with a grain of salt because num-ers are limited and procedures varied idely among studies—but still, the single

best performer on the entire chart was an echidna.

Buchmann and Rhodes conclude: "There is no evidence that the performance of echidnas is inferior to eutherian [placental] or metatherian [marsupial] mammals." They end by ridiculing the "quaint, explicitly or tacitly-held views that echidnas are little more than animated pin-cushions, or, at the best, glorified reptiles."

3. Gates (*Australian Zoologist,* 1978) studied learning in visual discrimination (black versus white, and various complex patterns of vertical and horizontal striping). His results parallel the other studies—echidnas learned quickly, at typical mammalian rates. But he added an interesting twist that confutes the only serious, direct argument ever offered from brain anatomy for monotreme inferiority—the claim that lack of a corpus callosum precludes transfer between the cerebral hemispheres, thereby compromising "higher" mental functions.

Gates occluded one eye and taught echidnas to distinguish black from white panels with the other eye. They reached "criterion performance" in an average of 100 trials. He then uncovered the occluded eye, bandaged the one that had overseen the initial learning, and did the experiment again. If no information passed from one cerebral hemisphere to the other, previous learning on one side of the brain should offer no help to the other, and the 100-trial average should persist. But echidnas only needed 40 trials to reach criterion with the second eye.

Gates conjectures that information is either passing across one of the other two commissures in the absence of a corpus callosum, or via the few optic fibers that do not cross to the other side of the brain. (In vertebrate visual systems, inputs from the right eye go to the left hemisphere of the brain, left eye to the right hemisphere; thus, each eye "informs" the opposite hemisphere. But about 1 percent of optic fibers do not cross over, and therefore map to their own hemisphere. These few fibers may sneak a little learning to the hemisphere dependent upon the occluded eye.) In addition, direct evidence of electrical stimulation has shown that inputs to one hemisphere can elicit responses in corresponding parts of the other hemisphere—information clearly gets across in the absence of a corpus callosum.

The solution to the paradox of such adequate intelligence in such a primitive mammal is stunningly simple. The premise—the myth of primitivity itself—is dead wrong. To say it one more, and one last, time: the reptilian features of monotremes only record their early branchin from the ancestry of placental mar mals—and time of branching is no me sure of anatomical complexity or ment status.

Monotremes have evolved separate from placentals for a long time—mo than enough for both groups to reach, b parallel evolution in independent lineage advanced levels of mental functioning pe mitted by their basic, shared mammalia design. The primary evidence for parall evolution has been staring us in the fa for a century; it forms part of the standa literature on echidnas, well featured ev in primary documents that uphold th myth of primitivity. We know that th echidna's brain attained its large size b an independent route. The platypus has smooth (if bulbous) brain. The echidn evolved the complex ridges and folds of cerebral surface as a special feature of own lineage. These sulci and gyri cann be identified (homologized) with the we known convolutions of placental brain The echidna brain is so different, by virt of a separate evolution to large size, th its convolutions have been named Greek letters to avoid any misplaced co parison with the different ridges and fol of placental brains. And Grafton Elli Smith, the man most puzzled by echid brains, did the naming—apparently wit out realizing that the very need for su separate designations embodied the dire evidence that could refute the myth primitivity.

In his eloquent plea for monotrem (1827), Geoffroy Saint-Hilaire wrote br liantly about the subtle interplay of fa and theory in science. He recognized t power of theory to guide the discovery fact and to set a context for fruitful int pretation. ("To limit our efforts to the si ple practicalities of an ocular examinati would be to condemn the activities of t mind.") But he also acknowledged the f side of useful guidance, the extraordina power of theory to restrict our vision, particular to render "obvious" facts nea invisible, by denying them a sensible co text. ("At first useless, these facts had remain unperceived until the mome when the needs and progress of scien provoked us to discover them.") Or Warner Oland, the Swedish pseudo-C ental Charlie Chan, once said in one of most delightfully anachronistic pseu Confucian sayings (*Charlie Chan Egypt,* 1935): "Theory like mist on e glasses. Obscure facts."

Stephen Jay Gould teaches biology, ge ogy, and the history of science at Harva University.

Disease and Death at Dr. Dickson's Mounds

The skeletal remains of prehistoric Native Americans show that agricultural revolutions can be hazardous to your health

by Alan H. Goodman and George J. Armelagos

Clustered in west-central Illinois, atop a bluff near the confluence of the Illinois and Spoon rivers, are twelve to thirteen poorly defined earthen mounds. The mounds, which overlap each other to some extent, cover a crescent-shaped area of about an acre. Since at least the middle of the nineteenth century, local residents have known that prehistoric Native Americans built these mounds to bury their dead. But it was not until the late 1920s that Don Dickson, a chiropractor, undertook the first systematic excavation of the mounds, located on farmland owned by his father. Barely into his thirties at the time, Dickson became so involved in the venture that he never returned to his chiropractic practice. Apparently, he was intrigued by the novel undertaking of unearthing skeletons and trying to diagnose the maladies of long-dead individuals. Later on, he became more concerned with the patterns of disease and death in this extinct group in order to understand how these people lived and why they often died at an early age.

The "Dickson Mounds" (the site also includes two early, unmounded burial grounds) quickly attracted the attention of professional anthropologists. In the early 1930s, a team of University of Chicago archeologists exposed about 200 of the estimated 3,000 burials and identified a number of settlement sites in a 100-square-mile area. A second phase of excavation at Dickson began in the 1960s under the direction of Alan Harn, an archeologist working for the state of Illinois, whose crew excavated many of the local living sites and more than 800 additional burials. The archeological research revealed that these prehistoric people had taken part in an important transition, from hunting and gathering to an agricultural way of life.

About A.D. 950, hunter-gatherers lived along the Illinois River valley area near Dickson, subsisting on a wide range of local plants and animals, including grasses and seeds, fruits and berries, roots and tubers, vines, herbs, large and small mammals, migratory waterfowl and riverine birds, and fish. The moderate climate, copious water supply, and rich soil made this a bountiful and attractive area for hunter-gatherers. Groups occupied campsites that consisted of a few small structures, and the debris scattered around these sites suggests seasonal use. The population density was low, perhaps on the order of two to three persons per square mile. Then, about 1050, broken hoes and other agricultural tools, as well as maize, began to form part of village refuse, evidence of the introduction of maize agriculture. At the same time, the population grew. By 1200 the population density may have increased by a factor of ten, to about twenty-five persons per square mile. Living sites became larger and more permanent. The largest settlement in the area, Larson, was a residential and ceremonial center where some 1,000 inhabitants lived, many behind a palisaded wall.

Trade also flourished. Dickson became part of what archeologists call the Mississippian tradition, a network of maize-growing, mound-building societies that spread throughout most of the eastern United States. More and more, items used at the village sites or deposited as grave offerings were not of local origin. Some, such as marine shell necklaces, came from as far away as the Gulf of Mexico and Florida, one thousand miles to the south. Everyday objects such as spoons and jars were received from peoples of the eastern plains and the western prairies, while luxury items of ceremonial or decorative value arrived in trade from the south, probably coming upriver to Dickson through Cahokia, a Mississippian center some 110 miles away. Cahokia is a massive site that includes some 120 mounds within a six-square-mile area. As many as 30,000 persons lived at Cahokia and in the surrounding villages.

What we know about Dickson might have ended at this point, but continues because the skeletal remains that Harn excavated have been used to evaluate how the

JUST WRITE FOR A VACATION.

We'll send you all the colorful facts about our fall and winter Caribbean cruises. 11 different itineraries, 5 to 16 days, 2 to 10 Caribbean ports. All aboard the MV Atlantic (Liberian registry). Write Home Lines Free Brochure, One World Trade Center, Suite 3969, New York, NY 10048. And see your travel agent. Write now.

HOME LINES CELEBRATED CRUISES

SOLID WOOD DECOYS

Reg. $65 NOW **$16.95**

"MALLARD"

ALL 14" LONG

The set comprises of: MALLARD DRAKE (Illustrated), MALLARD HEN, PINTAIL DRAKE, PINTAIL HEN, WOOD DUCK, & CANADA GOOSE

Traditional hand-painted ducks in authentic colors. These solid hand-sculptured decoys have all the details of others costing up to $300. Very heavy (2½ - 3½ lbs.). Solid mahogany, pine & oak.

$16.95 each, 2 or more only $14.95 each

A unique purchase enables us to offer them at this incredible price (due to devaluation of British pound). Plus $3.50 postage and handling ($2.50 per additional)

health of these prehistoric people fared following the adoption of agriculture and other changes in their life style. Interest in this issue stems from the writings of the eminent British archeologist V. Gordon Childe (1892–1957), who believed that the development of agriculture prompted the first great revolution in human technology, ushering in fundamental changes in economy, social organization, and ideology. Archeologists continue to debate the causes of agricultural revolutions. For example, some believe that in various regions of the world, increased population pressure, leading to food shortages and declining health, spurred the switch to agricultural food production. Others believe population increase was one of the consequences of agricultural revolutions. More important to us are the effects of an agricultural revolution on the health of people who lived at the time of such change.

Three circumstances have made it possible to test the effects agriculture had upon health at Dickson. First, Harn and those working with him valued the potential information to be gained from skeletons and therefore paid close attention to their excavation. Ultimately, the skeletal remains were sent to the University of Massachusetts at Amherst for analysis by George Armelagos and many of his graduate students (this is how we became involved). Second, the recovered remains include both individuals who lived before the development of maize agriculture (Late Woodland, or pre-Mississippian) and after (Mississippian). The two groups of individuals could be distinguished according to the mounds they were buried in, their placement within each mound and their burial position (in earlier burials the bodies tend to be in a flexed or semiflexed position; in later burials they tend to be extended). The third enabling condition was provided by Janice Cohen, one of Armelagos's graduate students. Her analysis of highly heritable dental traits showed that although Dickson was in contact with persons from outside the central Illinois River valley area during the period of rapid cultural change, outside groups did not replace or significantly merge with the local groups. It is therefore possible to follow the health over time of a single population that, for all intents and purposes, was genetically stable.

As a doctoral student working under Armelagos in the early 1970s, John Lallo, now at Cleveland State University, set out to test whether health at Dickson improved, got worse, or remained the same with the advent of agriculture and its accompanying changes. Lallo argued that intensification of maize agriculture most

likely resulted in a poorer diet. Although a common assumption is that the adoption of agriculture should have provided a prehistoric people with a better diet, there are good reasons to predict just the opposite. Heavy reliance on a single crop may lead to nutritional problems. Maize, for example, is deficient in lysine, an essential amino acid. Furthermore, agricultural societies that subsist on a few foodstuffs are more vulnerable to famines brought about by drought and other disasters. Finally, increased population density, a more sedentary life style, and greater trade, all of which are associated with agriculture, provide conditions for the spread and maintenance of infectious diseases.

The skeletons of individuals who lived before and after the introduction of maize agriculture were examined for a number of different health indicators, in order to provide a balanced picture of the pattern of stress, disease, and death that affected the Dickson population. The indicators that proved most sensitive to health differences were: bone lesions (scars) due to infection, nutritional deficiencies, trauma, and degenerative conditions; long bone growth; dental developmental defects; and age at death. To avoid unconscious bias, we and the other researchers involved measured these seven traits without knowing in advance which skeletons came from each of the two cultural periods.

Persistent bacterial infection leaves its mark on the outer, or periosteal, layer of bone. Tibias (shinbones) are the most frequently affected bones because they have relatively poor circulation and therefore tend to accumulate bacteria. Toxins produced by bacteria kill some of the bone cells; as new bone is produced, the periosteal bone becomes roughened and layered. Lallo and his co-workers found that following the introduction of agriculture there was a threefold increase in the percentage of individuals with such lesions. Eighty-four percent of the Mississippian tibias had these "periosteal reactions," as compared with only 26 percent of pre-Mississippian tibias. The lesions also tended to be more severe and to show up in younger individuals in the Mississippian population.

A second type of lesion, more easily seen in the thinner bones of the body (such as those of the skull), is a sign of anemia. In response to anemia, the body steps up its production of red blood cells, which are formed in the bone marrow. To accomplish this the marrow must expand at the expense of the outer layer of bone. In severe cases, this expansion may cause the outer layer of bone to disappear, exposing the porous, sievelike inner bone. This le-

How to Become a "Black Belt" in Verbal Self-Defense

For anyone who's ever been pulverized by put-downs, rankled by reproaches, or irritated by insinuations, here's a revolutionary book that devotes itself *completely* to tactics of verbal self-defense. *The Gentle Art of Verbal Self-Defense* teaches you how to defend yourself *diplomatically* in delicate family situations and in the hard-nosed business world. And this book is so thorough and easy-to-understand that you can read it once and become the kind of person everybody admires—the person who stays unruffled during confrontations, who always says the right thing, and who enjoys good relations with everyone.

Stop Them with a Few Words

This book explains the various ways that people will try to bait you and then it tells you how to *stop* them with a few carefully chosen words. It trains you to defend yourself with a simple eloquence that will subdue your verbal opponents. And it shows you how and when to use blunt honesty, agreement, humor, flattery, and distraction.

Keep Cool During Arguments

The Gentle Art of Verbal Self-Defense also helps you avoid the self-defeating, overly emotional attitudes that many people assume during arguments. Once you've read this book, you'll *never again* lose an argument by being sullen, uncontrollably angry, peevishly defensive, or apologetic. You'll have gained enough savvy not to be thrown by hostile remarks.

Learn to Handle *All* Attacks

The Gentle Art of Verbal Self-Defense covers all the types of verbal attacks and attackers you're likely to encounter. And it explains both attacks and defenses with helpful features like these:

- The 8 Types of Verbal Attacks (and how to fight them.)
- The 4 Principles of Verbal Self-Defense (from *knowing* you are under attack to *following through* with your counter-attack.)
- The 5 Personalities & How They Communicate (Is your boss a "leveller?" Is your mother a "blamer?" Is your husband a "distracter?")
- Dialogues that Show Effective & Ineffective Defense Strategies
- Instructions on Voice Control & Body Language

These features will teach you how to deal with all types of people, including bullying bosses, backbiting coworkers, guilt-producing mothers, nagging wives, condescending husbands, and many others. And you'll discover how to counter *all* the varieties of verbal abuse—from subtle put-downs to out-and-out attacks.

Save Yourself Years of Mistakes

The Gentle Art of Verbal Self-Defense gives you a complete education in communication, an education that will improve the quality of your personal and professional relationships. On your own, it might take you years of trial and error, of fights and misunderstandings, to learn all the lessons of this book. So, why not wise up *now* by ordering your copy of the book today?

The Gentle Art of Verbal Self-Defense, originally $12.95, now costs only $6.95. And, should you want to return the book, you can do so and have your money refunded with no questions asked.

About the Author

Psycholinguist Suzette Haden Elgin has presented her innovative self-defense principles in a variety of formats. She has given workshops and seminars all over the U.S., including verbal self-defense sessions for doctors, lawyers, and other professionals. Dr. Elgin has also created a self-defense tape and a training manual for people who teach her self-defense techniques.

sion, called porotic hyperostosis, can occur with any kind of anemia. In the Dickson Mounds populations, the lesions are not severe, are restricted to the eye sockets and crania, and occur mainly in children and young adult females. This pattern suggests anemia resulting from a nutritional deficiency, specifically an iron deficiency. (A hereditary anemia, such as sickle-cell anemia, would have been more severe in its manifestation and would have affected all ages and both sexes in the population.)

There is a significant increase in the frequency of porotic hyperostosis during the Mississippian period. Half the Mississippian infants and children had porotic hyperostosis, twice the rate found for pre-Mississippian infants and children. Individuals with both periosteal reactions and porotic hyperostosis tend to have suffered more severely from each condition. This may be evidence of a deadly synergism of malnutrition and infection, like that often reported among contemporary populations.

Traumatic lesions were measured by diagnosis of healed fractures of the long bones of the legs and arms. Adult males had the highest frequency of such fractures. Approximately one out of three Mississippian males had at least one fracture, twice the frequency of their predecessors. These fractures often occurred at the midshaft of the ulna and radius, the bones of the lower arm. Fractures at this location are called parry fractures because they are typically the result of efforts to ward off a blow.

The frequency of degenerative pathologies, including arthritic conditions found on joints and the contacting surfaces of the vertebral column, also increased through time. One or more degenerative conditions were diagnosed in 40 percent of pre-Mississippian adults but in more than 70 percent of Mississippian adults.

In addition to the studies of the changing pattern of disease and trauma, we, along with Lallo and Jerome Rose, now at the University of Arkansas, assessed differences in skeletal growth and developmental timing. Skeletal growth and development are susceptible to a wide variety of stressful conditions and therefore reflect overall health. We found that in comparison to pre-Mississippians of the same age, Mississippian children between the ages of five and ten had significantly shorter and narrower tibias and femurs (the major long bones of the legs). This difference may be explained by a decreased rate of growth before the age of five. The Mississippians apparently were able to catch up in growth after age ten, however, since adult Mississippians are only slightly smaller than pre-Mississippians.

A more detailed exploration of developmental changes came from studying defects in enamel, the hard white coating of the crowns of teeth. Ameloblasts, the enamel-forming cells, secrete enamel matrix in ringlike fashion, starting at the biting surface and ending at the bottom of the crown. A deficiency in enamel thickness, called a hypoplasia, may result if the individual suffers a systemic physiological stress during enamel formation. Since the timing of enamel secretion is well known and relatively stable, the position of such a lesion on a tooth corresponds to an individual's age at the time of stress.

We examined the permanent teeth—teeth that form between birth and age seven. For skeletons with nearly complete sets of permanent teeth, 55 percent of pre-Mississippians had hypoplasias, while among Mississippians the figure rose to 80 percent. In both groups, hypoplasias were most frequently laid down between the ages of one and one-half and four. However, the hypoplasias in the Mississippian group peak at age two and one-half, approximately one-half year earlier than the pre-Mississippian peak. The peak is also more pronounced. This pattern of defects may indicate both an earlier age at weaning and the use of cereal products as weanling foods.

The repeated occurrence of hypoplasias within individuals revealed an annual cy-

e of stress. Most likely there was a sea-nal food shortage. This seems to have orsened in the period just before the pulation becomes completely "Missis-ppianized," suggesting that it provided a tionale for intensifying agriculture.

All the above six indicators point to-ard a decrease in health associated with ltural change at Dickson. However, ey are not meaningful apart from an alysis of the pattern of death in these pulations. Healthy-looking skeletons, r example, may be the remains of young dividuals who died outright because eir bodies were too weak to cope in the ce of disease, injury, and other forms of ess. Conversely, skeletons that show ear and tear may be those of individuals no survived during stressful times and ed to a ripe old age.

At Dickson, however, the trend is un-nbiguous. Individuals whose skeletons owed more signs of stress and disease r example, enamel hypoplasias) also ed shorter lives, on average, than indi-duals with fewer such indications. For e population as a whole, life expectancy birth decreased from twenty-six years the pre-Mississippian to nineteen years the Mississippian. The contrast in mor-lity is especially pronounced during the infant and childhood years. For example, 22 percent of Mississippians died during their first year as compared to 13 percent of the pre-Mississippians. Even for those who passed through the dangerous early years of childhood, there is a differential life expectancy. At fifteen years of age, pre-Mississippians could expect to live for an average of twenty-three more years, while Mississippians could expect to live for only eighteen more years.

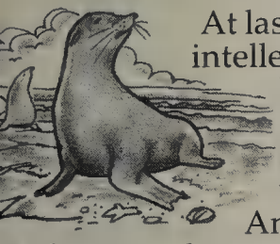
What caused this decline in health? A number of possibilities have been proposed. Lallo and others have emphasized the effect of agriculture on diet. Most of the health trends may be explained by a decline in diet quality. These include the trends in growth, development, mortality, and nutritional disease, all four of which have obvious links to nutrition. The same explanation may be offered for the increase in infectious diseases, since increased susceptibility may be due to poor nutrition. Furthermore, a population subject to considerable infectious disease would be likely to suffer from other conditions, including increased rates of anemia and mortality and decreased growth rates.

The link between diet and infectious disease is bolstered by an analysis of trace elements from tibial bone cores. Robert Gilbert found that the Mississippian bones contain less zinc, an element that is limited in maize. Building on this research, Wadia Bahou, now a physician in Ann Arbor, Michigan, showed that the skeletons with the lowest levels of zinc had the highest frequency of infectious lesions. This is strong evidence that a diet of maize was relied on to a point where health was affected.

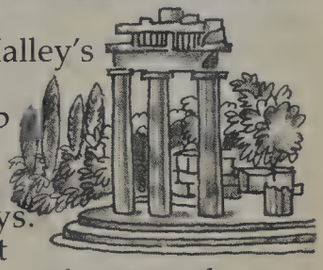
The population increase associated with the changeover to agriculture probably also contributed to the decline in health. We do not believe that the population ever threatened to exceed the carrying capacity of the bountiful Dickson area (and there are no signs of the environmental degradation one would expect to find if resources were overexploited). However, increased population density and sedentariness, coupled with intensification of contact with outsiders, create opportunities for the spread of infectious disease. George Milner of the University of Kentucky, while still a graduate student at Northwestern University, argued this point in comparing Dickson with the Kane Mounds populations. Kane is located near Cahokia, the major center south of Dickson. Despite Kane's proximity to this large center, its population density was

CRUISE TO MORE THAN A SUNTAN.

Introducing the Jason Journeys from December 1985 to October 1986.
Guest lecturer cruises to the greatest natural, cultural and historical wonders on earth.



At last, cruises that satisfy you intellectually as well as physically. You'll experience nature in the raw. The history of the ages. Cultures that live where time stands still. And instead of donning hip boots and mosquito netting, you'll see it all in the comfort of a beloved cruise ship called Jason.



Even a ringside seat for Halley's Comet.

All in the company of top scientists, historians, and explorers.

The Jason Journeys. First sea cruises that combine the sheer joy of sea travel with the thrill of discovery.

Talk to your travel agent. Or mail the coupon today.

The Galapagos, Amazon, Mediterranean, Adriatic, Black Sea, USSR, North Cape, Greek Isles, and more.

Eleven-day to 35-day cruises begin Dec. 22, 1985 from $1936 to $6846—with everything from the species that Darwin studied in the Galapagos and the awesome Chilean fjords to the palaces of Minoan kings and the minarets of Istanbul.

much lower than at Larson, the major agricultural village of the Dickson population. Of the two, Kane had the lower rate of infectious diseases.

While the "agricultural hypothesis," including the effects of population pressure, offers an explanation for much of the health data, it doesn't automatically account for the two remaining measures: degenerative and traumatic pathologies. Poor nutrition and infectious disease may make people more susceptible to degenerative disease. However, the arthritic conditions found in the Dickson skeletons, involving movable joints, were probably caused by strenuous physical activity. The link, then, is not with the consumption of an agricultural diet but, if anything, with the physically taxing work of agricultural production. An explanation for the increase in traumatic injuries is harder to imagine. Possibly, the increased population density caused social tension and strife to arise within communities, but why should this have happened?

A curious fact makes us think that explanations based only on agricultural intensification and population increase are missing an important contributing factor. Recent archeological research at Dickson suggests that hunting and gathering remained productive enterprises and were never completely abandoned. Many of the local Mississippian sites have a great concentration of animal bones and projectile points used for hunting. A balanced diet apparently was available. The health and trace element data, however, suggest that the Mississippian diet was deficient. There is a disparity between what was available and what was eaten.

At present our search for an explanation for this paradox centers on the relationship between Dickson and the Cahokia population. The builders of the Dickson Mounds received many items of symbolic worth from the Cahokia region, such as copper-covered ear spools and marine shell necklaces. Much of the health data would be explained if Dickson had been trading perishable foodstuffs for these luxury items. In particular, the diversion of meat or fish to Cahokia would explain the apparent discrepancy between diet and resources.

To have a food surplus to trade, individuals from the Dickson area may have intensified their agricultural production while continuing to hunt and gather. The increase in degenerative conditions could have resulted from such a heavy workload. The system may also have put social strain on the community, leading to internal strife. And the accumulation of wealth in terms of ceremonial or other luxury items may have necessitated protectio from outside groups. This would explai why the Larson site was palisaded. Bot internal and external strain may have le to the increase in traumatic pathologies

To test the validity of this scenario, w are hoping to gather additional evidenc concentrating on an analysis of trade. Th flow of perishable goods such as meat hard to trace, but we can study the sets c animal bones found at Cahokia and a Dickson village and butchering sites. Th distribution of animal bones at the archeo logical sites can then be compared wit examples of bone distributions in area where trading has been ethnographicall recorded. Further evidence is provided b data such as Milner's, which showed tha health at Kane—a community tha shared in Cahokia's power—was bette than at Dickson.

The trading of needed food for items c symbolic value, to the point where healt is threatened, may not seem to make sens from an objective, outsider's perspectiv But it is a situation that has been observe in historic and modern times. An indige nous group learns that it can trade some thing it has access to (sugar cane, alpaca turtles) for something it greatly admire but can only obtain from outside group (metal products, radios, alcohol). Th group's members do not perceive that th long-term health and economic results c such trade are usually unfavorable. No are all such arrangements a result of vo untary agreement. The pattern of healt observed at Dickson is seen in most situa tions where there is a decline in access to and control over, resources. For example lower classes in stratified societies liv shorter lives and suffer more from nearl all major diseases.

Agriculture is not invariably associate with declining health. A recent volum edited by Mark N. Cohen and George J Armelagos, *Paleopathology and th Origins of Agriculture*, analyzed healt changes in twenty-three regions of th world where agriculture developed. I many of these regions there was a clea concurrent decline in health, while in oth ers there was little or no change or sligh improvements in health. Perhaps a declin is more likely to occur when agriculture i intensified in the hinterland of a politica system. Groups living far away from th centers of trade and power are apt to be a a disadvantage. They may send the bes fruits of their labors to market and receiv little in return. And during times of eco nomic hardship or political turmoil, they may be the ones to suffer the most, as re sources are concentrated on maintainin the central parts of the system. □

The first collector's plate ever produced under the sponsorship of Encyclopaedia Britannica.

"The Cardinal"

by Kevin Daniel

An award-winning wildlife painter creates a bird portrait of unsurpassed authenticity and power.

Sunlight shimmers in the crisp spring air and dances on the iridescent feathers of this splendid cardinal pair. This is "The Cardinal," the first plate in the *Encyclopaedia Britannica* Birds of Your Garden series of limited-edition collector's plates.

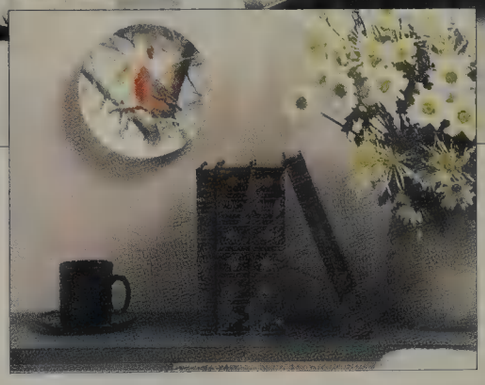
The effect is magical; it is as if Kevin Daniel has captured a fleeting glimpse of these handsome birds exactly as he saw them in his own garden. It is this almost uncanny sense that we observe unposed nature in Mr. Daniel's work that has thrust the young artist into the first ranks of contemporary wildlife painters.

"The Cardinal" is issued under the sponsorship of *Encyclopaedia Britannica*—the first time the *Britannica* name has ever been associated with a limited-edition collector's plate. That sponsorship is your assurance that Mr. Daniel's first work in the plate medium fully matches his award-winning oils and prints in the accuracy of its portrayal.

Indeed, "The Cardinal" is unique among all Mr. Daniel's work for one critical reason: the artist's lucent colors glow with a special brilliance on the pure white "canvas" of an Edwin M. Knowles china plate. This is wildlife art of the very highest quality that will bear eloquent witness to its owner's taste for many years to come. And if you act now, you can have "The Cardinal" at the eminently affordable $19.50 issue price. But, please note: "The Cardinal" is issued in an edition strictly limited to 100 firing days, and you may well find yourself competing against a legion of collectors and bird enthusiasts for this superb fine-art plate.

Now is the time to act to assure yourself "The Cardinal" at issue price; if, for any reason, you should decide later that you aren't fully satisfied, you'll enjoy the protection of our 365-day guarantee. *If you are not completely satisfied, you may resell your plate to us at any time within one full year after you receive it.* We will issue you a check for everything you have paid, including postage, without the necessity of a resale transaction.

You'll also receive a free copy of *Plate World* magazine when you place your buy-order for "The Cardinal." *Plate World* is the definitive word on the fine art of plate collecting, filled with the kind of valuable information you'll need to buy and trade plates. To grace your home with "The Cardinal" by Kevin Daniel, and to receive your free copy of *Plate World*, simply complete the buy-order form and mail with your check or money order to: The Bradford Exchange, 9345 Milwaukee Avenue, Niles Chicago, Illinois 60648.



The plate is shown smaller than the actual size of 8½ inches in diameter.

The Rainmakers

A succession of individuals have devoted their talents to milking the clouds—and the people

by Gerald Carson

When the nomadic societies of primitive hunters and gatherers settled down as agriculturists, they acquired a more abundant food supply, and along with it a paralyzing fear that the rains would not come and the crops would wither. But perhaps nature's droughts could be controlled. The wish led to the belief that such a goal was achievable.

And so sorcerers and great chiefs and priests arose to act as rainmakers. They were wiser than common men or at least cleverer, guardians of secret charms, intercessors presumably capable of conciliating the gods or angry spirits. All were, according to the late social anthropologist Sir James George Frazer, "more or less conscious deceivers," which does not rule out self-deception.

One approach to rainmaking was based upon sympathetic, or imitative, magic; that is, the notion that like produces like, that the effect resembles the cause. So some tribes squirted water on each other or imitated the calls of aquatic birds or, as in Uganda, set out pots of water to draw down the rain when the pasturage failed. Animal sacrifice was believed to be effective provided the animals were black, the color of storm clouds. Later came the idea of a pantheon of gods who controlled the phenomena of nature. Among the Greeks, rain was supposed to come from the supreme deity, Zeus, who poured water through a sieve: Homer speaks in the *Iliad* of "the rain of Zeus." The Romans' sky god was Jupiter. In time of drought the women of Rome, with bare feet and streaming hair, went in procession up the slope to the Capitol, seat of the Jupiter cult, to offer prayers. And a millennium later, the people of Santa Barbara, in southern California, petitioned the mission authorities to allow them to carry the Virgin, Nuestra Señora del Rosario, in procession through the town with prayers and supplications for rain.

Plutarch, writing of a great battle that occurred in 102 B.C., believed that noise produced rain. Since nature's rain was accompanied by thunder, people might get the same results in the same way. This association of ideas eventually came to link weather control with concussion. In the sixteenth century Benvenuto Cellini wrote that he had brought on rain by artillery fire. Church bells have been rung in France and Italy to jar the air and so wring precipitation from the skies, and a modern scholar, Clark C. Spence, a professor of American history at the University of Illinois, has noted that "shooting with cannon, handguns, and rockets, was common in the Beaujolais wine districts almost to the twentieth century."

The concussion theory is probably the most widespread and durable of all popular beliefs connected with compelling the skies to give up their moisture. In the United States there was the opinion that the Fourth of July is usually wet because of the patriotic noise released during an old-fashioned Fourth. In 1880 U.S. patent No. 230,067 was granted to Daniel Ruggles of Virginia, a former Confederate general, who owned a ranch along the Rio Grande in Texas, for a scheme to send up a balloon loaded with explosives. Ruggles encouraged the ideas of another concussionist, Edward Powers, a Chicago civil engineer, who wrote an influential book, *War and the Weather; or, The Artificial Production of Rain* (1871).

Powers listed some two hundred battles that were accompanied by rain. Since most battles were fought in the temperate zone, with rain expected on an average of

Devices for making rain are set up in Nebraska. Drought makes the Great Plains the natural habitat of the rainmaker.

Lenox.

Tea at the Ritz

Lenox tribute to American fashion—
created under the guidance of our
country's leading costume experts.

Individually crafted of fine
handpainted porcelain.
Available only by reservation.

1902. The turn of the century has brought
iting new fashions to America. A young
y is on the way to meet her gentleman
nd for tea. She is impeccably dressed for
occasion with a mouton-trimmed hat,
ar, bodice and muff. Her "visiting dress" of
y broadcloth, trimmed with silk appliqué,
resents the height of fashion of the day.

ea at the Ritz has been created by Lenox
er the guidance of distinguished fashion
norities—Vera Maxwell, renowned fashion
igner; Carrie Robbins, award-winning
adway costume designer; Robert Riley,
nion Institute of Technology; and Matthew
rnan, Costume Society of America. This
ely figurine represents one of the most
portant eras in American fashion and is
orically accurate down to the finest detail.

A Handcrafted Work of Art

ceived and designed by the artists of
ox and created exclusively under their
ction by master craftsmen in Japan, each
rine is individually crafted of the finest
que porcelain—capturing *extraordinary*
il from the furry texture of the muff to the
ving *art nouveau* floral designs on the
t, bodice, and long, flowing sleeves.

killed artisans paint each piece *by hand,*
ting a delicately colored work of art of
mparable beauty. And each figurine is em-
ished on its base in *pure 24 karat gold* with
itle and the world-famous Lenox trade-
k... the symbol of unsurpassed quality
craftsmanship. Of course, *your satisfac-*
is completely guaranteed.

Available Only Direct from Lenox

at the Ritz is available only by reservation
ct from Lenox and will not be sold through
n the most prestigious dealers or galleries.
original issue price is $95, payable in
venient monthly installments of $19 with
inance charge. Each figurine is accom-
ied by a Certificate of Authenticity and
ature on the history of American fashion.

e each figurine is individually hand-
ted, please allow 6 to 8 weeks for shipment.
ervations are accepted in strict sequence of
ipt and should be received by September 30,
. To order, mail your Reservation Applica-
, or call **TOLL FREE 1-800-228-5000** now.

MEMBERS'
NEW YORK
WEEKEND

NEW YORK, NATURALLY!

MEMBER'S NEW YORK WEEKEND

(Designed exclusively for Members of the American Museum of Natural History)

Whether your first love is art or archeology, elegance or evolution, stars of the heavens or stars of Broadway, you'll find it in our Members' New York Weekend. For three exciting days and two wonderful nights, ■ great Museum and a great city will be all yours.

The Weekend program includes:

- Two nights in one of New York's finest hotels: The Waldorf Astoria, The Plaza, or The Parker Meridien.
- A complimentary lunch and breakfast.
- Free tickets to the Hayden Planetarium and the extraordinary Naturemax Theater.
- A free copy of the Official Museum Guide.
- A free Highlights Tour.
- Personalized Service to help customize your weekend to suit your needs and tastes.
- ■ Special Discount Airfares.

Only $92.50 per person per night, tax included (based on two nights, double occupancy). Special discount rates also available for individuals and families.

For more information:
Call: 800 435-8776
(in N.Y. State call 212 595-1567)

about every three days, opponents pointed to coincidence as the explanation. However, Powers, Ruggles, and U.S. senator Charles B. Farwell lobbied successfully to get the federal government into rainfall experiments. In 1891, without the blessing of professional meteorologists, Congress directed the Department of Agriculture to conduct experiments with explosives. The tests were carried out by a Washington patent attorney, Robert St. George Dyrenforth. He exploded both ground charges and balloons filled with a highly combustible mixture.

Results? Well, it depended upon the angle of vision. One day rain fell. Another it didn't. When .02 inches was recorded, the *Washington Post* charitably called it "a hard rain." On another occasion, when the weather bureau had predicted showers, a thunderstorm dropped its load of wetness, but mostly somewhere other than where it was supposed to. The press ignored this geographical discrepancy, and the *New York Sun* sang: "I am cloud-compelling Dyrenforth, a might able wight; I can call the clouds together with a load of dynamite."

But *Puck*, the humorous magazine of the period, expressed its skepticism poetically, too: "And while they watch for drops of water,/It falls just where it hadn't orter/By tons, in every other quarter."

The topic of making rain through concussion may be concluded by reference to a prominent businessman who spent some $50,000 on a hunch. During 1906 and 1907, Charles W. Post, the Battle Creek, Michigan, breakfast food millionaire, acquired 213,324 acres of high plains land in Garza, Lynn, and Hockley counties, Texas, but found that lack of water made it impossible to develop his properties as he had hoped. Post had talked with many Civil War veterans about their wartime experiences and concluded that artillery fire and rain were connected. Rain followed thunder. Cannons made thunder. Why not find out once and for all if a bombardment of the sky could produce rain? "I don't undertake the task of rain-making as a disciple of science," the Battle Creek empiric explained, "but because the crops . . . need rain."

Explosives attached to kites were discharged over the area in a series of spectacular "rain battles," and also at Battle Creek, where, following the aerial warfare, a soaking rain descended. The U.S. Weather Bureau pointed out, however, that it rained that day from the Great Lakes to the Pacific Ocean. Rain doctoring, *Scientific American* commented, was an incurable disease.

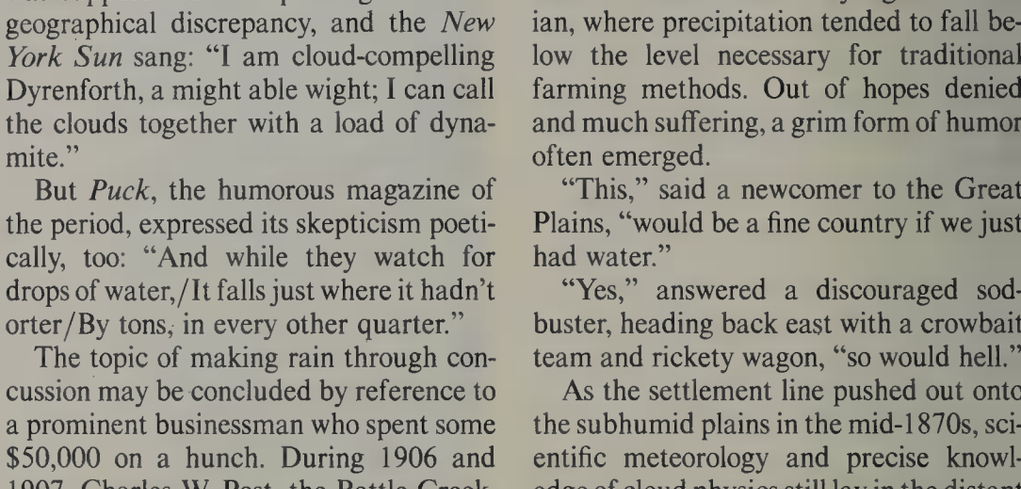
The elemental human need for rain intensified west of the ninety-eighth meridian, where precipitation tended to fall below the level necessary for traditional farming methods. Out of hopes denied and much suffering, a grim form of humor often emerged.

"This," said a newcomer to the Great Plains, "would be a fine country if we just had water."

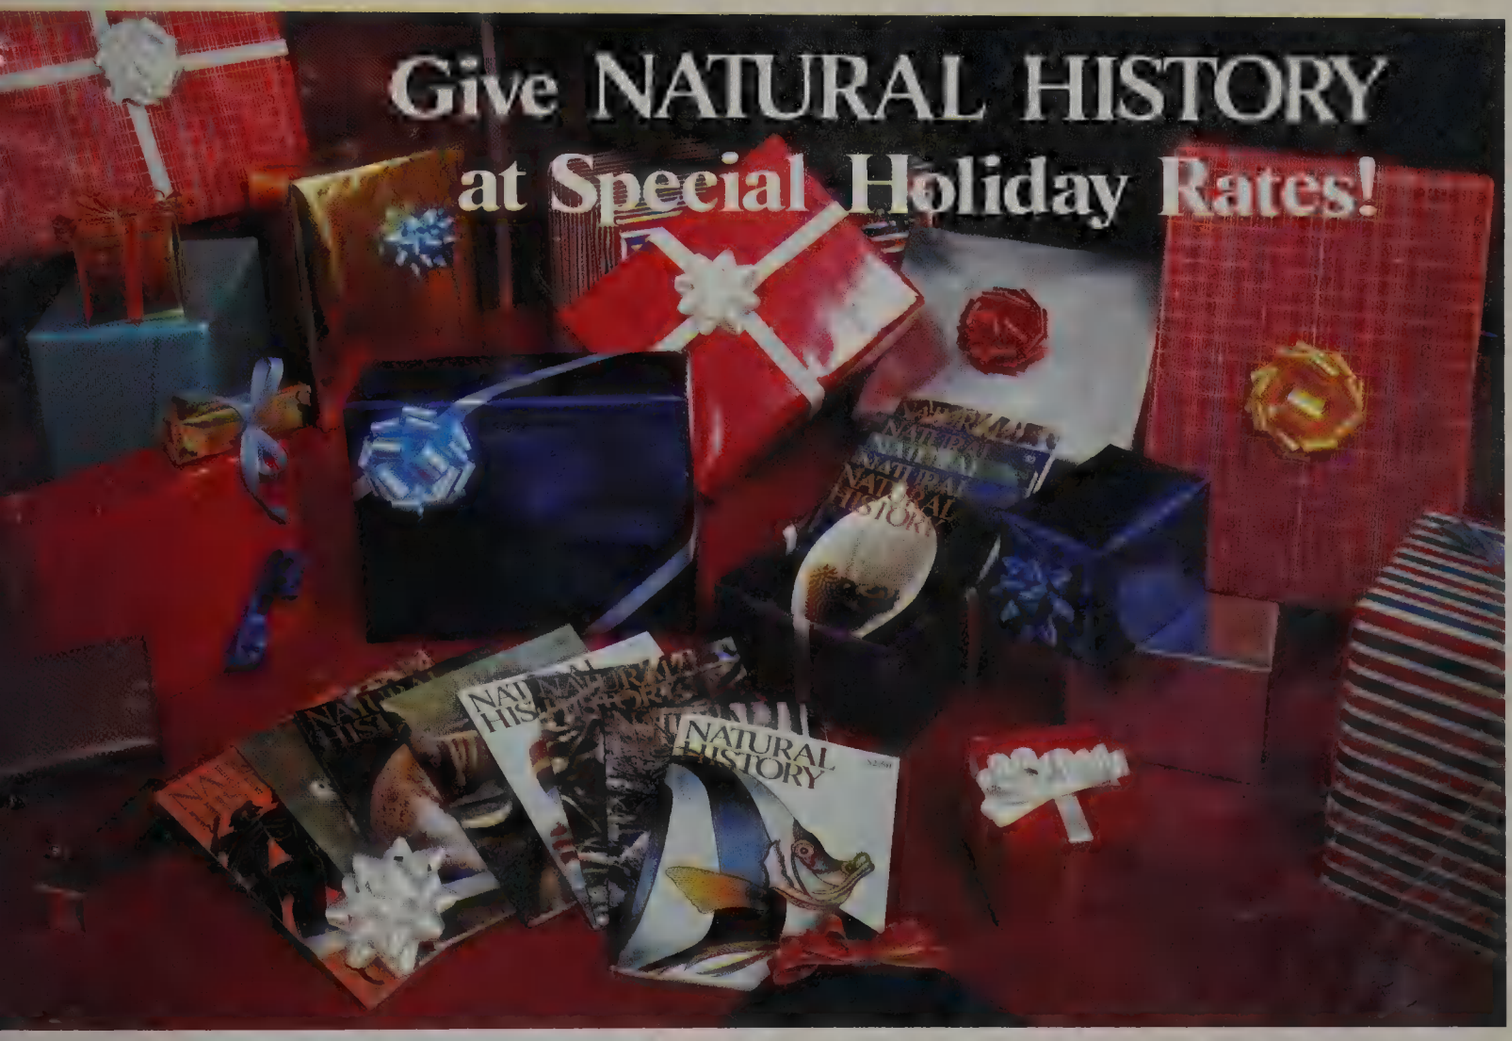
"Yes," answered a discouraged sodbuster, heading back east with a crowbait team and rickety wagon, "so would hell."

As the settlement line pushed out onto the subhumid plains in the mid-1870s, scientific meteorology and precise knowledge of cloud physics still lay in the distant future. There was a general indifference to theoretical science in the United States during much of the nineteenth century; a "get ahead" economic philosophy emphasized the immediately useful. Exceptions

Scientific American



The Dyrenforth Rainmaking Expedition in Texas (1892) exploded ground charges and balloons in an effort to make rain.



This holiday season give the **distinctive gift** that is inexpensive and easy to give. **Natural History** is the perfect holiday gift that keeps giving all year long.

It's inexpensive—only $20 for your first gift
It saves you money—only $14 for each additional gift
It's easy—Use the postage paid cards in the magazine or call the toll-free number listed below.

Your gift recipient(s) will receive a valuable membership card that entitles him or her to all the benefits listed on the right. You'll be able to announce each gift with an attractive gift card we will send you as soon as we receive your order.

Give the gift of Natural History and membership in the American Museum today!

Your Gift brings all these Benefits:

- A one year subscription to Natural History (12 issues)
- Free admission to the American Museum of Natural History
- Access to the air-conditioned Members' Lounge
- Travel opportunities led by Museum scientists to all parts of the world
- Discounts on artwork, books, crafts, jewelry, and other gift items from our Museum shop
- Admission to special features and programs
- A valuable membership card
- Free ticket to our NatureMax Theatre

AMERICAN MUSEUM OF NATURAL HISTORY

The day he left the village of his childhood for America.

His family gathered around him on that chilly November day to bid him final farewell. Papa put up a brave facade.

He sensed his brother's awkwardness when they embraced. And, most clearly, he felt a pang of sadness as he looked for one last time into Mama's tearful eyes.

Then the approaching train's high-pitched shriek broke the silence. And his family was suddenly left far behind.

The right choice.

o come to mind, such as Joseph Henry, rst secretary and director of the Smithsoian Institution, an investigator who did asic work in electromagnetics and initited the use of telegraphic reports for veather predictions and storm warnings; nd Joseph Leidy, a naturalist who made ontributions of permanent value in every ranch of zoology. To the list may be dded the name of James P. Espy, a serius student of cloud thermodynamics, vho as early as 1830 described the upvard movement of warm air as the precondition to the formation of clouds, the ooling of the air, and the condensation of s moisture into raindrops. Espy was ever regarded as a fraud, but neither was e a success. He ended up with a modest iche in a government bureau, studying torms without producing any. So folk befs filled the knowledge vacuum. In adition to the concussion theory, other deas that gained acceptance included:

- The notion that plowing up the land nade it rain, a doctrine warmly embraced by the rainbelters—those farmers who ettled on the semiarid plains during a wet ear, relying upon a continuance of the generous rainfall. Abnormally heavy rainfall after the Civil War seemed to confirm he maxim, "Rain follows the plow."

- A theory that railroad and telegraph ines increased rain because of the electricity in the wires or in the current running along the steel rails.

- The idea that planting trees induced ain, which makes it understandable that he first Arbor Day was celebrated in 872 in Nebraska.

- The release of chemical gases to induce ain.

- And prayer. Whether the showers that lways finally came were of divine origin or not, it was incontrovertible, as a saying of the short-grass country had it, that "every dry spell ends with a rain."

Maybe, it was said, the climate was changing—wishful thought based upon he misinterpretation of the natural cycles of weather. Farmers on the hard-soil buffalo-grass plains said, "The country is becoming more seasonable." Hope fathered he thought. And when the corn wilted in he heat—the leaves curled up and the ears were only nubbins—when the pastures turned brown and the rain barrel was ow, then desperate men saw shimmering mirages of freshwater lakes and embraced he expedients of despair. The moment for he entry of the rain wizard had come.

Many of them are now forgotten—rogues, mystics, opportunists, flat-earth believers, self-deluders—but some left a mark. Clayton B. Jewell was a dispatcher for the Chicago, Rock Island, and Pacific Railroad Company who attracted the attention of Rock Island officials because of experiments he had made with rockets and gases. Good crops would bring emigrants, boost land values, generate freight traffic. So the Rock Island fitted out a special laboratory car, eventually expanded to three cars, for the rainmaker and his associates. They toured Kansas and made sorties into Oklahoma, Texas, Nebraska, and South Dakota. As with all the rain compellers, Jewell's formulas and methods were secret, but curious observers did

report glimpses of bottles, pipes, tanks, electric wires, and a pipe in the car's roof from which chemicals escaped. Jewell claimed he had brought down rain sixty-six times. On one occasion, according to a Kansas newspaper, so much precipitation followed the magician's ministrations that a farmer implored Jewell to put a stop to the deluge or his calves would drown. Jewell replied rather jauntily: "Machine's wound up for ninety days. Same price for stopping as for starting. Teach the calves to swim." Other railroads showed some interest but the Rock Island dropped the experiments. Jewell moved on to California, where he failed to milk the clouds near Los Angeles. He died in 1906 doing what he did best, dispatching trains for the Missouri Pacific at Coffeyville, Kansas.

Frank Melbourne, a born gambler and con man, was known as the Australian

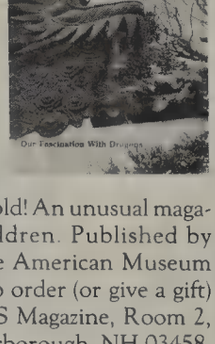
Museum Members entitled to $2.50 discount off subscription price!



Rain Doctor. The newspapers were well supplied with accounts of the wonders the cloud manipulator had performed or was going to, and they obliged by calling him the Rain Wizard. His charge was $500 or $150, according to what the traffic would bear, and he guaranteed to produce rain in three days. Like most of the "precipitators" Melbourne promised "no rain—no pay," but there were ways of juggling the odds. Melbourne usually set up his apparatus at an agricultural fair where he released gases from chemicals he said were previously unknown to science. The theory was that drops of moisture coagulated around the particles of rising gas and came down as rain. If it rained in the wrong place, the professor explained that the wind had caused the gases to drift.

Sometimes rain followed Melbourne's demonstrations and sometimes it didn't, but the Rain Wizard's reputation was badly damaged when it became known that his secret equipment included a barometer and that the dates he chose for his performance coincided with the weather forecasts of a popular almanac widely respected for the accuracy of its predictions. Melbourne was a kind of shooting star—up and then out—the beneficiary of shrewd publicity and human gullibility.

Melbourne's career was profitable enough to inspire a school of imitators in Kansas and Nebraska: a former county clerk, a bank cashier, a "colonel" in New Mexico, a "professor" with a "powerful rain machine." There were also some imaginative cloud crackers whose activities were not necessarily chargeable to Melbourne's influence, though they may have found his success inspirational. A versatile Missourian named Dorman, who manufactured artificial diamonds, a laxative, and wrote poetry, brought forth the Continental Rain-Making Company and used both chemicals and a shotgun. A "doctor" with the improbable name of George Ambrosius Morrison Sykes, who believed the earth was flat, was, despite eccentricities, a salesman of such awesome capabilities that the *New York World* said he could sell the Brooklyn Bridge "without even getting up a sweat."

At Goodland, Kansas, a clutch of corporate entrepreneurs—franchisers, we would call them today—created the Inter-State Artificial Rain Company (which either purchased or stole Melbourne's "system"), the Swisher Rain Company, and the Artificial Rain Company. All of these opportunists could read the almanacs and the barometer and had access to the Signal Service weather maps. Like medical doctors of the period, rain doctors were not called in until the case was desperate. So a rain could reasonably be expected without human intervention. It was a bet the rainmakers often won. In case of a cloudburst, a lawsuit for damages would be no disaster but, rather, a great coup, since it would constitute legal proof that the pluviculturist did indeed make it rain.

The last and most spectacular of the producers of meteorological fantasies was Charles M. Hatfield, a former sewing machine salesman with a ninth-grade education. As a result of experiments conducted on his father's farm in San Diego County, California, Hatfield announced that a combination of twenty-three chemicals, properly aged and evaporated from galvanized pans on top of wooden towers or platforms, produced a "chemical affinity with the atmosphere." He explained his principle in vague but impressive jargon. One is reminded of Starbuck, the central character in the N. Richard Nash play *The Rainmaker*, who explains, "I look up at the sky and I say 'Cumulus!' I say 'Cumulus-numbus! Nimbulo-cumulus!'" Sure enough, after this bizarre incantation, rain came down "in buckets, rain in barrels, fillin' the lowlands, floodin' the gullies."

In addition to his use of scientific mumbo-jumbo, Hatfield also understood the persuasive power of understatement. "I do not make rain," he insisted. "That would be an absurd claim. I merely assist Nature. I only persuade the moisture to come down." It was, he said, "a mere matter of cohesive attraction." Since southern California is a semiarid region, the natural habitat of the road runner, the horned toad, and turkey buzzard, of sagebrush and cactus, the eternal search for water made Hatfield's evaporators a familiar sight. For nearly a quarter of a century he conducted some five hundred demonstrations, for fees varying from $50 to $10,000. His apparent successes made some southern California municipalities fearful that he couldn't put the genie back into the bottle, especially after a dam at Lake Moreno broke with heavy damage and loss of life. Sixteen inches of rain fell in two days. The city of San Diego offered to pay the rain magician's fee only if he would relieve the city of damage suits amounting to some $3,500,000. Obviously Hatfield chose not to collect and departed in considerable haste, well armed and without his $10,000.

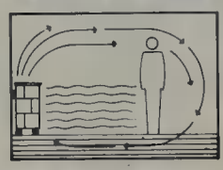
At the high point of his career, Hatfield enjoyed the courtesy title of "professor," and he became something of a folk hero like Paul Bunyan or Pecos Bill. In recognition of his fame, the Native Sons of the Golden West erected a historical monument of red granite to "Hatfield, the Rain-

How WESO puts the *pleasure* back into wood heat.

More comfortable, more convenient—and far safer than ordinary stoves—WESO's civilized ceramic tile stoves make other stoves seem prehistoric by comparison. And their rich, handcrafted exteriors have a beauty no iron stove can match...

Touch any other type of stove while it's operating and you could get a serious burn. But you *can* touch the tiles of a WESO Ceramic Tile Stove—even lean against them—while the stove fills your rooms with wonderful warmth. Such unsurpassed safety is just one of the reasons experienced woodstove users are switching to these intelligently-designed, splendidly efficient tile heaters. Here's another example:

WESO warmth is very different from most stove heat. A typical radiant stove bakes you on one side while you freeze on the other *(See the illustration to the right)*. The farther away you stand, the chillier you feel. Build a small fire and you have to huddle near the stove; build a big fire and you can't get near it!



But the WESO's uniquely-engineered "ceramic shell" design moves warm air naturally all around your room. You get a mild yet penetrating warmth—never harsh or scorching—plus remarkably *even* temperatures floor to ceiling, anywhere you stand. No roasting, no "cold spots," no noisy electric blower needed. Many people actually prefer WESO heat to furnace heat.

Our stoves won't make you change your lifestyle just to enjoy the pleasures and savings of burning wood. They offer every convenience you could ask for, including easy firestarting and operation; a sophisticated automatic thermostat that ends constant tending; a pull-out ash pan for mess-free cleaning; and a tempered glass window to let you see the fire. You can burn coal, too, without any costly "conversion kit."

There's never any rust, no exterior maintenance. The tile sections can be easily removed, so installing or moving your WESO isn't a struggle. And while most stoves require at least 3 feet between themselves and combustibles, you can safely place furniture as close as 9" to WESO tiles. That saves a *lot* of valuable room space.

In sum, WESO Stoves offer these and many other advantages most cast-iron and soapstone stoves are *physcially incapable* of duplicating. Send today for our FREE color stove portfolio and let us tell you the complete story.

Membership/ Subscription Problems?

We Want To Help!

Sometimes, all you need is information. Here are some helpful facts:

Orders – Changes of Address

It takes us from 6 to 8 weeks to process an order, a payment, a renewal, a change of address, or any kind of adjustment to your membership/subscription. So count on about 6 to 8 weeks from the time you place an order until the time you get your first magazine. If you send us a change of address, count on the same 6 to 8 weeks before the magazine is delivered to your new address. (And remember, when registering a change of address, be sure to give us your old address as well as your new one.)

Bills – Renewals

If you send us a payment, you may receive another bill, or even two, before the payment is recorded, and the computer is told to stop sending you bills. Don't be concerned. Just ignore the extra bill. If you send us a renewal, you may receive one or even two more renewal notices before the renewal is recorded, and the computer is told to stop sending you renewal notices. Please respond to only one notice and ignore the extras. And remember, if you wait until just before your membership/ subscription expires to renew, you may miss one or even two issues before the renewal is recorded. Renew early to avoid this possibility!

New Offers

If you are already a member/subscriber, and you receive a new member/subscriber's introductory offer from us, it's because we have used another reputable organization's mailing list. We aren't perfect. We try to screen out our own subscribers' names from these lists to save money, but sometimes it isn't possible. If there is even the slightest difference in the name and/or address (for instance, Mary Roberts and M. Roberts, or Mrs. Roberts, or 12 Oak Road and 12 Oak) the computer can't tell that it's the same name. So we'd appreciate it if you'ld simply give that introductory offer to a friend you think might enjoy Natural History.

Missed Issues

If you miss one or more issues, it may mean that your name and address have been entered incorrectly on our computer, or that we haven't received your payment, or renewal instructions. Or the Postal Service may have failed to deliver the copy that we sent. If you miss one or more issues, please contact us. With your help, we'll rectify whatever mistake was made.

Problem Correspondence

If you have written to us about a problem and not received an answer, please don't be upset. We may have been able to solve the problem without further correspondence. If the problem persists, though, don't hesitate to contact us directly. Remember to give us your complete return address as it appears on your magazine label, or we won't be able to write back.

For help or information on your membership/subscription, write:

Natural History Membership Services

Keep this Ad in case a problem arises.

We're anxious to give you the best possible service. Your co-operation will help us to do that. Thank you!

AMERICAN MUSEUM OF NATURAL HISTORY

Central Park West at 79th Street, New York, N.Y. 10024

maker" with an inscription describing the Moreno flood. When it was pointed out that the rainmaker's success was based upon knowledge of rain cycles, the use of weather charts, and delaying tactics until a drought was far advanced, the true believers pointed out that all great scientists had to bear the ridicule of the ignorant and the envious. Didn't they scoff at Copernicus and Marconi? Not until 1936, when Los Angeles drew Colorado River water from Boulder (now Hoover) Dam, did Hatfield's evaporators disappear from the California scene.

We reach the final, or at least the latest, chapter in the history of rainmaking through the concept of cloud seeding. In the 1920s a man named L. Francis Warren, often addressed as Dr. Warren be-

U.S. Air Force Photo

Dry ice pellets for seeding clouds are poured into a hopper on an Air Force plane.

cause of some unspecified connection with Columbia University, engaged the interest of a Cornell University chemist, Wilder D. Bancroft. Professor Bancroft, who held an authentic doctorate from the University of Leipzig, joined with Warren and the U.S. Air Force, which was interested in the military potential of weather control. Bancroft was attracted to Warren's idea that electrically charged sand particles sprayed from an airplane would bring down the rain. But the U.S. Weather Bureau countered Warren's enthusiastic press releases trumpeting uncanny successes; they declared that the approach was "picturesque and plausible" but "entirely futile." Electrified sand suffered the fate of all the methods that had preceded it: results were not conclusive. Statistical proof of effectiveness was lacking. The government lost interest and the necessary infusion of private capital never materialized.

Following the same idea of condensation nuclei, other theorists and inventors proposed various materials for sprinkling the skies—ammonia, carbon dioxide, sulfuric acid, chlorate of potash and Dry Ice, a trade name for carbon dioxide in a solid state. Arthur Brisbane, who wrote editorials for the Hearst newspaper chain during the reign of William Randolph Hearst, was able, because of his prominence, to go directly to President William Howard Taft, to promote liquid-air bombs and dust bombs. And some years later, still engrossed with the rainmaking idea, Brisbane proposed to President Warren G. Harding that powdered lime be dropped into the clouds. But the weather bureau pointed out that lime is a drying agent and the suggestion was filed.

More recent cloud-seeding attempts have been made with silver iodide crystals, notably by Dr. Irving Langmuir, the Nobel Prize-winner in chemistry, and his associate Vincent J. Schaefer. Together they worked on methods for de-icing aircraft wings during World War II. These investigations, according to Langmuir's biographer, Albert Rosenfeld, "led to controversial postwar experiments in seeding clouds for purposes of 'artifical rainmaking.' " It was in Langmuir's attempt to modify the weather "that he gained his most widespread celebrity."

In fact, controlling rain may not even be desirable; there are too many imponderables. Moving precipitation from one area to another produces no social benefits while possible risks include floods, erosion, more insect pests, and the proliferation of disease germs and noxious weeds. Or plant pathogens might flourish with changed conditions of temperature and moisture. Meanwhile a thorny legal question remains still unsettled: to whom does the weather belong?

Ultimately, the western farmer learned to adapt to a semiarid climate through irrigation, specially developed seeds, windmills, and the techniques of dry farming. So the rainmaker, with his smooth tongue and magnetic personality, a worthy analogue to the medical charlatan, faded from the scene, leaving a picturesque and slightly raffish footnote to American social and cultural history.

Gerald Carson, author and social historian, is a frequent contributor to Natural History.

American Museum of Natural History

Voyage of the Vikings
Oslo to Dublin
August 12 to 28, 1986

Cruise with five expert lecturers of the American Museum through the breathtaking fjords of Norway and the remote islands of the North Sea and Scotland. Join Dr. Thomas D. Nicholson, American Museum Director and astronomer, along with a Museum art historian, anthropologist, geologist, and ornithologist. Learn of the symbolism of Celtic and Norse art; the geological formation of fjords, firths, and forths; and share splendid birding excursions. Our exclusively chartered vessel, *Illiria*, is the finest small passenger cruise ship in the world (only 74 cabins). To receive a detailed brochure call the Museum at (212) 873-1440, or send the coupon below.

With the Grain

Throughout the Third World, it is the staple that defines the meal

by Raymond Sokolov

We talk, logically enough, about staple grains in our American diet. Wheat is certainly basic enough to the way we eat to qualify for this fundamental role in our nutritional patterns. It is rightly called the staff of life. Corn is its nearest rival and surpasses wheat altogether in the diets of Native Americans and Hispanics. And we all know that other cultures have based their cuisines on other grains: rice, oats, barley, millet, and so on.

The general notion of a staple is obvious. A staple is a basic source of food energy, a starch or carbohydrate eaten at virtually every meal. For most people, staples begin as grasses, whose seeds yield varying amounts of carbohydrate and protein, as well as other nutriments. But not all staples come from grains. The potato and the cassava plant (manioc) are the chief exceptions to the crucial role of edible grass in human survival.

But looking more closely at the specific ways in which individual cultures employ their staples, we can see immediately that evolved Western cuisines have moved some distance away from primary dependence on staples. For us, bread is the main form in which wheat comes to the table. At most, it is an accompaniment to the main dishes of a menu. Restaurants and cookbooks never list bread as a separate course. And many of us in this country eliminate bread entirely from our evening meals (although we eat masses of it as toast at breakfast or in sandwiches).

Even the more traditional French serve bread as an ancillary part of their meals. They, like us, fill their plates with animal protein, vegetables, dairy products, and all the other foods that modern agriculture can supply so dependably and with such delectable variety.

To replace starch with meat as the center of the meal is a sign of prosperity, a sign that a culture can afford to feed livestock with grain, quite inefficiently, instead of using it for human fodder. Italians have taken this step much like the rest of the industrial West, but they have held on to the pasta course as a starch-centered reminder of a more basic diet.

Ironically, pasta is now at the heart of the vogue of *nouvelle cuisine*. In three-star

Famine victims in Ethiopia cook grain supplied by a relief program.

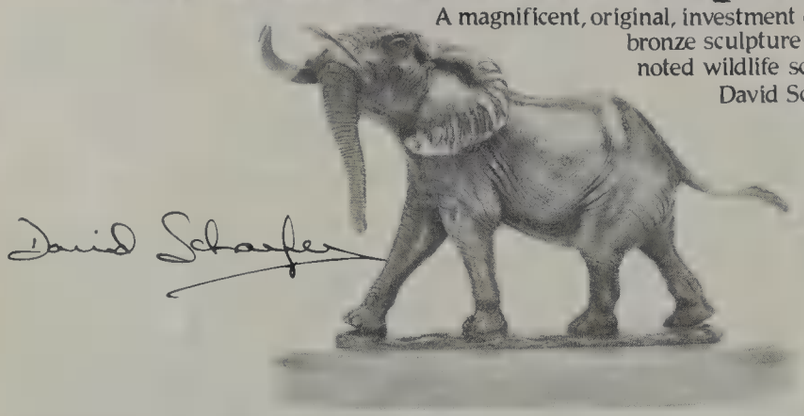
ATC Presents in an Exclusive Limited Edition

The Schaefer Bull Elephant

A magnificent, original, investment quality bronze sculpture by the noted wildlife sculptor, David Schaefer.



shown smaller than actual size of approximately 7¾" high x 12" length (including walnut base)

- **Individually hot cast in true bronze and hand finished to a lustrous patina**
- **Individually serially numbered, hall-marked and registered**
- **Certificate of authenticity**
- **Personal letter hand signed by David Schaefer**
- **All Things Creative's "No Questions Asked" Full Guarantee**
- **Exclusively issued in a single limited first edition of 6500 serially numbered sculptures**

This original and new "bookshelf size" masterpiece is a true David Schaefer bronze sculpture offered at a fraction of the investment of other larger Schaefer sculptures. The Schaefer Bull Elephant is the first in a series of limited edition "bookshelf size" African wildlife sculptures by David Schaefer.

This powerful, authentic, hand-crafted bronze elephant is the perfect size to showcase in home or office. We are absolutely certain you will be thrilled with your Schaefer Bull Elephant. Each sculpture is backed by All Things Creative's "No Questions Asked" full guarantee of satisfaction. If for any reason you wish to return your sculpture, just do so within 30 days and receive a full refund.

To order your "Schaefer Bull Elephant" at only $395.00 simply return the application with payment by check or charge it to your credit card.

French restaurants, you will be presented elite ravioli stuffed with lobster and floating on a refined sauce. No yuppie restaurant in this country would dare to write a menu without at least one exotic pasta concoction at the head of the list.

Nevertheless, I think few of the affluent customers in these modish establishments pause between forkfuls to reflect that they have reverted to the basic nutritional solution of the Third World. Pasta is, after all, nothing more than a convenient form of wheat, easy to store, shaped for quick cooking. In a typical pasta dish, the noodles form the overwhelming bulk and are flavored with a sauce normally composed of some more lavish form of protein and other flavorings to relieve the tedium of the basic mass of starch.

The simplest pasta I can think of would be tossed with oil and garlic and then sprinkled with cheese. More elaborate pasta dishes merely add other ingredients, without altering the fundamental notion: plenty of starch enlivened by smaller amounts of other foods.

This pattern, so rare in the Western diet as to be notable, is the normal structure of eating in the majority of households on the planet. Throughout the Third World, staple starches—not disguised by the relatively high technology that converts wheat to pasta or bread—are embellished with other food elements. But it is the starch that defines a meal.

China is the chief example. In his introduction to *Food in Chinese Culture,* K.C. Chang of Yale University wrote that the base of the Chinese dietary system is the division between *fan,* grains and other starch foods, and *ts'ai,* vegetable and meat dishes.

To prepare a balanced meal, it must have an appropriate amount of both *fan* and *ts'ai,* and ingredients are readied along both tracks. Grains are cooked whole or as flour, making up the *fan* half of the meal in various forms: *fan* [in the narrow sense, cooked rice], steamed wheat-, millet-, or corn-flour bread, *ping* [pancakes], and noodles. Vegetables and meats are cut up and mixed in various ways into individual dishes to constitute the *ts'ai* half. Even in meals in which the staple starch portion and the meat-and-vegetable portion are apparently joined together, such as in *chiao-tzu* [Chinese dumplings], *pao-tzu* [steamed bun with fillings], *hun t'un* [wonton], and *hsien-ping* [pan-fried bun with fillings], they are in fact put together but not mixed up and each still retains its due proportion and own distinction.

This parallelism carries through to cooking utensils, which are sharply divided between *fan* and *ts'ai* vessels. And, Mr. Chang says, the *fan-ts'ai* dichotomy

s so basic to Chinese thinking about food hat a Chinese cook presented with an American larder will produce a "Chinese" meal constructed according to the *fan-ts'ai* principle.

The universality of this principle has allowed Chinese to assimilate a wide number of staples in the *fan* category: rice, millet, *kao-liang* (a sorghumlike grain), wheat, maize, buckwheat, yam, and sweet potato. In our Chinese restaurants virtually the only *fan* we normally see is rice, but the basic principle is graphically illustrated when ethnic Chinese sit down at the table and deposit the *ts'ai* part of the meal on top of their rice, usually served in a separate bowl, and then consume the two types of food in combination.

Typical American diners in an American-Chinese restaurant often dispense with rice entirely. Waiters have learned to ask starch-averse Americans if they want to order rice. And even Americans who do order rice never think of it as the indispensable center of the meal. Like us, however, the Chinese, according to Mr. Chang, add more lavish amounts and kinds of *ts'ai* to their *fan* if they can afford it. The logical conclusion must be that the basic meal must have *fan* and whatever *ts'ai* can be scraped together.

This system of culinary thought, evolved from necessity, is alive in all the great rice-based cuisines of Asia. Hundreds of millions of people operate on the assumption that a meal is rice *and* something else. But the starch comes first and is always there.

In west Africa, this principle operates at its most basic. Millet reigns supreme; served as a porridge or in solid, dried "loaves," it is the "*fan*" of millions. The seeds of this nutritious grass are sold in the United States primarily for birdseed, but health food stores, impressed by millet's food value, carry it for human consumption. It makes an interesting alternative to rice or potatoes in a standard American meal. And serving millet from time to time is an easy way to give ourselves a taste of Africa (see recipe).

The taste of staple grains is, of course, extraordinarily important to the people who eat them every day. Rice connoisseurship in the Far East is not just a fetish of gourmets. Everyone cares about distinctions of texture and perfume. Rice may have become a staple grain because riziculture was practical for survival, but it is now so deeply a part of culinary life that it is impossible to imagine Asia without it. In the case of a rice famine, it would not solve the problem to ship wheat flour across the Pacific. Millennia of habituation to rice could not be easily wiped away by good

BEING KNOWN AS A NUMBER CAN BE A VERY PERSONAL THING.

JF 1222146

Look, for example, at the individual registration number on the back label of your bottle of Beefeater Gin. If it were the one on the left, it would tell you that your Beefeater was distilled Thursday, January 7, 1982, under the supervision of Thomas Bowman, Master Stillman, and that the distillation was approved personally by Mr. Norman Burrough, a direct descendant of our founder, before it was allowed to leave the distillery.

Does it help to know all this? Yes. That number is a vital part of Beefeater Gin's quality control.

Because the number is Mr. Bowman's personal signature. And Mr. Burrough's, as well.

And any artist is at his best when he has to sign his work.

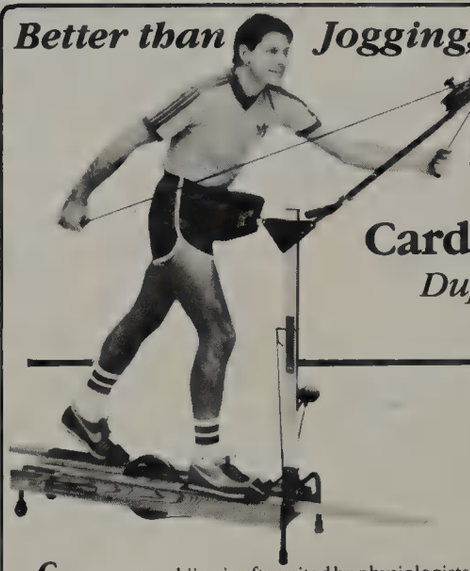
Better than Jogging, Swimming, or Cycling...



NordicTrack
Jarless Total Body
Cardiovascular Exerciser
Duplicates X-C Skiing for the Best Motion in Fitness

Cross-country skiing is often cited by physiologists as the most perfect form of cardiovascular exercise for both men and women. Its smooth, fluid, total body motion uniformly exercises more muscles so higher heart rates seem easier to attain than when jogging or cycling. NordicTrack closely simulates the pleasant X-C skiing motion and provides the same cardiovascular endurance-building benefits–right in the convenience of your home, year 'round. Eliminates the usual barriers of time, weather, chance of injury, etc. Also highly effective for weight control.

More Complete Than Running

NordicTrack gives you a more complete work out-conditions both upper body and lower body muscles at the same time. Fluid, jarless motion does not cause joint or back problems.

More Effective Than Exercise Bikes

NordicTrack's stand-up skiing motion more uniformly exercises the large leg muscles and also adds important upper body exercise. Higher pulse rates, necessary for building fitness, seem easier to attain because the work is shared by more muscle mass.

Even Better Than Swimming

NordicTrack more effectively exercises the largest muscles in the body, those located in the legs and buttocks. When swimming, the body is supported by the water, thus preventing these muscles from being effectively exercised. The stand up exercising position on the NordicTrack much more effectively exercises these muscles.

A Proven, High Quality Durable Product

NordicTrack is in its 7th year of production. NordicTrack is quiet, motorless and has separately adjustable arm and leg resistances. We manufacture and sell direct. Two year warrantee, 30 day trial period with return privilege.

Folds and stands on end to require only 15" x 17" storage space.

intentions and classes in breadmaking.

At the very least, an immense effort of palatal and culinary reeducation would be required, with all the government apparatus and social control that such a complete disruption of normal life implies. This is exactly what seems to be happening in Ethiopia, where the authoritarian Mengistu regime is attempting to force the populace to accept the grain shipments sent by generous outside countries to alleviate the famine brought on by years of drought.

The problem in Ethiopia is especially severe. Added to the general conditions that have plagued the entire sub-Saharan Sahel region—bad weather, political turmoil, and primitive transport facilities—is the very special problem of Ethiopia's staple grain, teff.

Teff (*Eragrostis abyssinica*) is the cornerstone of Ethiopian culinary culture. Ground into flour, fermented, and then cooked like a large pancake, it is the basis for *injera*, Ethiopia's unique, flat, spongy bread. In a typical meal, the table is covered with *injera*, and other foods are arranged on top. Still other pieces of *injera* are provided, and diners pick up food from the table with torn-off pieces of the bread. After all the food has been consumed from the table, the *injera* that has been absorbing the juices is itself torn apart and eaten.

In Ethiopia, the lack of teff is a major political issue. On-scene news reports at the beginning of the summer indicated that most of the teff seed in Ethiopia had been eaten during the famine. And even though the rains had finally come, it looked as though farmers would have to plant sorghum and potatoes. Those were the seeds available from the outside, and many Ethiopians would be lucky if transportation could be found to bring even those undesirable seeds to them. But there was apparently nowhere at all to turn for teff seed.

Perhaps there are worse disasters than the disappearance of a diet based on a rare grain. In a generation or two, if the rains hold up and the four-wheel-drive trucks get through, Ethiopians will have forgotten teff and will have switched to sorghum *injera* or mashed potatoes. But a unique way of life will have been lost, unnecessarily.

Teff seed does exist, right here in this country. The drooping flower panicles of this plant wave in American gardens, where it is sometimes planted as an ornamental. The English-language vernacular name of the genus is "love grass," a direct translation of the Greek *Eragrostis*. Garden Magic Company (P.O. Box 6570, Zephyr Cove, NV 89449) sells the seed.

No doubt there is not nearly enough seed available right now to supply the needs of millions of Ethiopians. But there could be. If the U.S. Department of Agriculture promoted large-scale planting through subsidies and price supports in the time-honored manner, in a few years, American farmers could resupply Ethiopia with all the seed it needs to resume its traditional teff cuisine. In the end, a culture would be saved, and we would have an extremely powerful bargaining chip with which to exert benign pressure on the Mengistu regime for democratic reform.

Raymond Sokolov is a writer whose special interest is the history and preparation of food.

Tuo Zaafi

(West African millet dish adapted from Ellen Gibson Wilson's *A West African Cookbook*, Avon Books)

1 cup millet meal
½ teaspoon salt (optional)

1. Mix the millet meal with enough cold water to make a thin paste.
2. Bring 1½ cups water to a boil in a heavy pan, with salt if used.
3. Pour the meal paste into the boiling water. Lower heat so that the water barely simmers. As the mixture thickens, stir to prevent burning. It should take 15 minutes for the meal to expand fully and to soften to the consistency of porridge.
4. To serve, dip a large spoon into water and then into the *tuo*. Put a scoop carefully on each plate.

Yield: 1 to 2 servings

Sweet-Sour Millet

(Adapted from Adelle Davis's *Let's Cook It Right*, New American Library)

1 crushed bay leaf
½–1 teaspoon salt
1 cup millet
1 clove garlic, finely chopped
⅛ teaspoon ground nutmeg
2 tablespoons oil
2 tablespoons vinegar
2 tablespoons brown sugar

1. Bring 2 cups of water (or stock) to a boil in a heavy saucepan with the crushed bay leaf and salt.
2. Add millet in a slow stream. Reduce heat and simmer slowly for 15 minutes, uncovered.
3. Add remaining ingredients, stir, and simmer another 5 minutes, or until the millet is quite tender.

Yield: 4 servings

After emerging from a night's rest in the ventilation shaft of a termite mound, a group of dwarf mongooses may spend a half an hour or so on their toilet before starting off on the day's foraging expedition. Hornbills, birds that frequently associate with mongooses, wait in nearby trees for the food search to begin.

J.B. Davidson

A Taru Life Story

In eastern Kenya, the dwarf mongoose forms an unlikely partnership with the desert birds

by O. Anne Rasa

Any list of mutualistic relationships would be heavily weighted toward the highly organized, impersonal world of the insects. The story of ants protecting and "milking" their cattlelike aphids, for example, is well known. Much less common is evidence of mutualism among warm-blooded vertebrates, and mutualistic relationships that cross taxonomic class lines, say, between birds and mammals, are especially rare. But in the Taru Desert of Kenya, I discovered just such a mutualism between the dwarf mongoose *Helogale parvula* and two species of hornbill. This relationship appears to be the closest known mutualism for any vertebrates and is comparable only to that found between ants and other insect species.

The Taru Desert is an enormous, flat area of semidesert bushland, dominated by the frankincense tree. It extends sixty miles inland from the coast of Kenya and stretches from the Tanzanian border in the south to the Somali border in the north. The region's only water sources are water holes, which are dry for more than half the year. From January to March, the hottest time of the year, temperatures reach 116° F in the shade. To survive, the animals that live permanently in the Taru must be able to obtain water from their food. Among the species indigenous to this harsh environment are the highly social dwarf mongooses and dry-bush hornbills.

Dwarf mongooses live in matriarchal families—in my study area there were about twelve animals in each group—and display a highly advanced degree of division of labor and altruistic behavior. Depending generally on its age and sex, a mongoose may serve the group by baby-sitting, attacking predators, driving away intruding mongoose groups, or acting as a guard to warn of a predator's approach. These roles, however, are not exclusive or permanent, and any group member can take over any of them as needed. Dwarf mongooses are also the only mammals, except humans, known to care for sick and injured members of the group. (Reports of such "nursing" behavior in lions, elephants, and dolphins have so far not been scientifically documented.)

The smallest of all mongooses, dwarf

Two dwarf mongooses, right, perch on top of a termite mound and stand guard while the rest of the group forages. Their task is to alert the group by repeating a loud warning call when raptors or other predators approach. When hornbills join a foraging group, below, the mongooses often employ fewer guards, taking advantage of the bird's ability to stop predators.

O. Anne Rasa

mongooses are almost entirely insectivorous. Unlike their more strictly carnivorous relatives, they feed mainly on beetles and grasshoppers, but mice and larger arthropods, such as spiders, scorpions, and centipedes, are a preferred part of their diet. Their preferences for grasshoppers and larger prey items overlap almost entirely with those of the two hornbill species with which they associate—the Von der Decken's hornbill (*Tockus deckeni*) and the yellow-billed hornbill (*T. flavirostris*).

The hornbills' family life, while not as gregarious as the mongooses', is also a tightly knit affair. Once mated, the birds stay together for several years. A close pair bond is important because during nesting—which may take place twice a year—the female is entirely dependent on her mate for her survival and that of their young. Hornbills nest in holes that they find in living trees. After the female has laid one or two eggs, she gradually walls herself in with a mixture of mud and feces, leaving only a small slit open to the outside. The slit is big enough to allow the male to feed her but too small to allow a predator, even a snake, to enter. While thus immured, the female molts all her flight and tail feathers and is unable to fly. Only after the eggs hatch and her new feathers have grown does she break down the protective wall and join her mate in provisioning the chicks. At this point, she usually has spent from six to seven weeks within the nest cavity.

The elder of her chicks immediately rebuilds the wall. As each chick matures, it, too, breaks out. With each breakout, the wall is rebuilt until each young hornbill has left the nest. Although the hornbill's social life differs dramatically from that of the mongoose, elaborate cooperative behavior characterizes both systems and may have aided the evolution of their mutualistic association.

The first time I encountered a group of mongooses foraging in the Taru Desert, they were accompanied by a large flock of birds. Von der Decken's and yellow-billed hornbills were present, as were the smaller red-billed hornbills (*T. erythrorhynchus*), white-crowned shrikes (*Eurocephalus anguitimens*), African drongos (*Dicrurus adsimilis*), and lilac-breasted rollers (*Coracias caudata*). As the mongooses wandered through the tussocky grass, the hornbills hopped behind or right in the middle of the group, while the other birds fluttered from tree to tree to keep up. Everywhere the mongoose group passed through the grass, grasshoppers, locusts, and moths flew up, only to be caught, usually in midair, by one of the birds. At first I thought the birds were simply stealing potential prey from the mongooses. Only after observing the animals and collecting data for months did I become aware of the true extent of the relationship.

I soon realized that the birds, especially the hornbills, actively sought the association with the little mammals. Dwarf mongooses generally seek shelter at night in the ventilation shafts of active termite mounds. The hornbills may have regular roosting areas, sometimes as much as a mile and a half away, but in the morning, they arrive and wait in the trees around the mound for up to three-quarters of an hour until the first mongoose emerges. The birds may then wait another half hour for all the mongooses to finish their morning toilet on the mound (a ritual that involves grooming, defecating, and marking territories with their scents) before starting off on the daily foraging expedition.

Such patience suggests that the wait is worth it. And the birds' arrival at the right termite mound suggests that they are very likely the same birds that accompanied the mongooses on the previous day. Because dwarf mongooses are nomadic—they may wander more than one-third of a mile per day and rarely spend more than one night in the same termite mound—it is likely that the birds rely on more than luck to locate the mound.

At times, the Von der Decken's and yellow-billed hornbills become agitated during the mongooses' morning ritual and actively attempt to hasten the mongooses' departure from the mound. At this point they adopt what I call their "chivying" behavior, which usually involves flying onto the mound, landing among the grooming mongooses, and walking demonstratively toward the base of the mound, where they wait briefly before repeating the process. This sequence continues until the mongooses leave. The birds may adopt a more extreme form of chivying if they have waited for more than an hour for the mongooses to emerge from the mound in the morning. In such a case, a bird flies down onto the mound, peers into the ventilation shafts, and calls, making a rhythmic "wok-wok-wok" sound. This approach gets a quick response; the mongooses ap-

O. Anne Rasa

pear immediately and leave the mound within four minutes.

But the mongooses are by no means passive partners in the association. They, too, appear to count on their morning rendezvous. Sometimes there are no hornbills waiting in the trees when the mongooses emerge from the mound because the birds have been disturbed in the early morning hours by predators or large herds of ungulates. More commonly, the disturbance has taken place the previous evening, driving off the hornbills before they could see where the mongooses had taken shelter for the night. In either case, when no hornbills appear, the mongooses are slow to begin the day's foraging, taking almost twice as long to leave the mound, even when other bird species are present. And if either Von der Decken's or yellow-billed hornbills arrive before the mongooses have given up and left without them, the mongooses then depart quickly: the longer they have waited, the faster they leave.

The advantage of the association for the two hornbill species is easy to understand: because hornbills and mongooses eat many of the same foods, hornbills can profit from the mongooses' foraging efforts. But the Von der Decken's and yellow-billed hornbills are not the only birds known to follow the mongooses. Why, then, has the mutualism evolved only between the mongooses and these two species? All of the other bird species are just as likely to forage in mixed-species bird flocks as they are to join a mongoose group. I have often seen these birds leave a group of mongooses to join a passing flock. Significantly, these other birds feed primarily on smaller insects; none includes larger prey in its diet. The two hornbills, in contrast, share the mongooses' taste for mice and large arthropods, and it is in competition for these items that they have the advantage. The mongooses are effective in finding and flushing a mouse, for example, from its hiding place in the grass, but if it escapes them, the more agile hornbills are more likely to make the final capture. Of all the birds, therefore, these two large hornbill species are the ones with the most to gain from associating with the mongooses. This may also explain why I rarely saw them when they weren't in the mammals' company.

Interestingly, hornbills never attempt to kill young mongooses, even though they are smaller than the rats that hornbills are known to catch and eat. On many occasions, I have seen a hornbill pick up a young mongoose that was begging for an insect held by an adult, fling the little mammal to one side, and then try to steal the insect from the adult mongoose's mouth. Most likely, the juvenile mongooses simply don't behave like prey—for one thing, they don't respond to the hornbills as raptors—but whatever the reason, hornbills show no inclination to kill the goose that lays the golden egg.

For the mongooses, the advantage of the association is based on protection from predators, especially birds of prey. The Taru is rich in raptors, not only in the number of species but also in the number of individual birds. It is also along one of the main migration routes for Palearctic and intra-African migrants. Mongooses spend about 18 percent of their foraging time hiding from avian predators. On average, a group is disturbed by raptors 12 times a day and attacked 1.3 times.

Many—but not all—of the raptors that prey on mongooses also prey on the hornbills. The hornbills' response to avian predators is straightforward: they explode into vertical flight and land in the nearest tree, where they hide among the branches while making very slow "wok" sounds. The mongooses have developed a more complicated, highly effective antipredator behavior. One member of the group—usually a subadult male—climbs to an elevated position in a tree or on a termite mound, from which it scans the surroundings while the rest of the group forages. Should it sight a predator, the guard warns the group by repeating a loud warning call; variations in the call indicate whether the predator is in the air or on the ground. On hearing the warning, the other members of the group run for cover—in termite mounds, in holes, under bushes, and in fallen trees.

Depending largely on how fast or slow the group is moving, as many as six guards may be present at one time: the slower the rate of foraging, the larger the number of guards. On average, guard duty lasts about fifteen minutes, but it may stretch to three-quarters of an hour. During this time, guards do not feed. Guarding is the most dangerous of the many roles played by the members of the mongoose group. The guards usually bring up the rear of the foraging group, and the only successful attacks I have observed on adult mongooses have been on guards running to catch up to the rest of the group, which may have wandered more than 250 feet away. The guard has to cover this distance alone and is thus especially vulnerable to an attack from the air.

The speed of the group, however, is not the only factor that determines the number of guards. I compared how many guards were present at any one time with the number of birds accompanying the group at that moment and was surprised to find a strong correlation: the more birds that are present, the fewer guards there are. With ten hornbills or more (I have seen as many as twenty-six), the mon-

Kenneth Fink; Bruce Coleman, Inc.

The yellow-billed hornbill, right and below, is one of several bird species that benefit from foraging with mongooses. As the little mammals work their way through the grass, they disturb a variety of insects and other arthropods, many of which are snatched up by the agile birds. Bottom: The smallest of all mongooses, the dwarf mongoose is primarily insectivorous, but it will prey on mice when the opportunity arises.

O. Anne Rasa

Bill Gabriel

gooses often go so far as to put up no guards at all, seeming to rely entirely on the hornbills to warn them of a predator's approach. When the birds spot a predator and give their warning, the mongooses run and hide, rarely bothering to utter warning calls of their own.

Such a system can work only if the hornbills warn of all mongoose predators, regardless of whether the birds themselves are at risk. (Although the two hornbills and the dwarf mongoose have many of the same predators to worry about, some raptors attack the mongoose but not the birds.) Many bird species have an inborn knowledge of what the raptors that prey on them look like; this enables them to flee at the first sight of an appropriately sized or shaped bird or even a shadow. If such knowledge is inborn rather then learned, I doubted that the hornbills would be able to recognize and respond to predators that threaten only the mongooses. And yet they do. Some of the Taru's raptors are too small (for example, the shikra, *Accipiter badius*) or too weak (the grasshopper buzzard) to capture hornbills, even young ones, which, by the time they emerge from the nest hole, are as large—if not larger—than their parents. Both these birds, however, elicit warning responses from the hornbills, and both kill mongoose young. The buzzard, the brown snake eagle (*Circaetus cinereus*), and the pale chanting goshawk (*Melierax poliopterus*) are the most dangerous mongoose predators.

Von der Decken's and yellow-billed hornbills are apparently also able to identify birds of prey that are not a threat to the mongooses. Neither the birds nor the mongooses are alarmed by the kestrel (*Falco tinnunculus*), the lesser kestrel (*F. naumanni*), or the red-footed falcon (*F. vespertinus*). These relatively small raptors are Palearctic migrants, and by the time they arrive in the late spring, the young mongooses are already too large for them to catch. Sometimes, kestrels and falcons even join the foraging group.

Thus, what appeared initially to be a fairly simple exchange of benefits—with the mongooses flushing food for the birds, in return for the birds announcing the approach of predators—has turned out to be a complicated mutualism of, most likely, long evolutionary standing. The mongooses' "commitment" to the relationship has led them to alter their guarding behavior—a highly effective (albeit dangerous to the individual guard) intraspecific defense against predators. The hornbills have had to learn to recognize and respond to raptors that do not threaten them but do threaten the mongoose, while at the same time passing up opportunities to attack young mongooses. Both bird and mammal benefit substantially from the association, and both have altered their behavior to a degree not previously reported for any social vertebrates involved in a mutualistic relationship. To survive the Taru desert environment, mongooses and hornbills seem to have adopted the motto: "Together we stand, divided we fall." □

Travel with the lecturers of the American Museum

Alaska Wildlife Adventure
June 27-July 10, 1986.
Majestic Glacier Bay. Awesome Mount Denali (McKinley). Tundras, flower-filled meadows, icebergs, craggy peaks, volcanos. You owe yourself the sight of America's great wilderness. Juneau. Katmai National Park. The Chugach Mountains. Nanana River. See humpback and killer whales, mountain goats, caribou, moose, grizzly and Kodiak bears, Dall sheep and countless shore birds. Optional excursion to the remote Pribilof Islands (July 10-14). Basic Tour cost: $4,500. per person.*

The Natural History of Hawaii
Feb. 19-March 4, 1986.
Discover the rich marine life and geology of Hawaii from a naturalist's vantage point. View Humpback whales at the height of the mating and calving season. Explore tidal pools, lava tubes, and lush valleys. Exotic fish, waterbirds, sea turtles, tree ferns, fuschia flowers. Panoramic vistas. Ancient animistic rock carvings. $1,995. per person.*

Archeology Tour to Mexico
Jan. 6-30, 1986.
Mexico's colorful history and landscapes blend with your escape from winter. Archeological excavations, jungles, verdant coasts and dramatic mountain ranges. The Pyramid of Quetzalcoatl, Oaxaca, Mitla, Monte Alban, Palenque, Campeche, Uxmal, Chichen Itza, Merida. The anthropology museum of Mexico City. The gardens of Cuernavaca. Xochicalco. Zempoala. Puebla. Teotihuacan. $2,300. per person.*

Caribbean Christmas on the Sea Cloud
Dec. 22, 1986-Jan. 5, 1987.
Celebrate Christmas and New Years sailing aboard the legendary tall ship, *Sea Cloud*. On deck with 36 sails set, you will enjoy an exhilirating experience no standard Caribbean cruise program offers. During the holidays join Museum lecturers for swimming, snorkeling and birding at ports-of-call which include Antigua, St. Martin, St. Bartholomew, Martinique, Barbados, Mustique and Palm Island. $5,290-6,890. per person.*

Trinidad and Tobago Wildlife Tour
April 14-23, 1986.
A snorkelers and birders paradise! An underwater rainbow of tropical fish and coral. Sandy beaches, lush rain forests with trogons, kingfishers, Scarlet Ibis, boobies, Motmots, Chachalacas. $1,950. per person.*

Amazon Wildlife Adventure
June 21-28, 1986.
Experience the unrivaled diversity of fauna and flora, the beauty and tranquility of nature's mightiest river: the Amazon. Over 4,000 bird species. Exquisite butterflies. Sloths, tapirs, caimen, capybaras, giant tree frogs and more. A mysterious environment, full of contrasts. Ceiba trees, giant Victoria lilies, orchid-laden trees. Optional extension to the famed Incan sites of Cuzco and Machu Picchu (June 28-July 3). Basic Tour cost: $1,498. per person.*

French Caves and Castles
May 2-15, 1986.
Discover prehistoric caves, medieval castles, chateaus and gastronomic delights wit Museum art historians and paleontologists. Explore historic towns and churches, view famous art collections and cave art normally not available to the public. $3,50 per person.*

Anthropology Tour to Morocco
March 21-April 5, 1986.
An insider's view of a diver land. Mountains, oases, a beautiful coast. Marrakech Fes, Tangier, Rabat, Casablanca. Mosques, markets palaces, archeological digs casbahs, museums, tombs cultural crossroads where Phoenician, Roman, Turki Arab, Jewish and French influences left their mark. $1,750. per person.*

Zambia, Zimbabwe and Botswana Safaris
Sept. 12-28 or Sept. 26-Oct. 1986.
Join nature and photography experts in one of the world's greatest wildlife areas: the Luangwa and Wanki National Parks, the Okavango Delta an the Kalahara Desert. The full moon will grace our stay at breathtaking Victoria Falls. Superb birding and big game viewing. Black and White Rhinoceros, elephants, giraffe zebra, wild dogs, hyenas. $3,8 per person.*

Solomon Butcher's Pioneers

An itinerant Nebraska photographer captured a generation of sodbusters

by John E. Carter

It was land, raw and powerful and new, that brought people west. Solomon D. Butcher, an itinerant Nebraska photographer, captured the land and the homesteaders who settled it. A pioneer who photographed pioneers, Butcher left a legacy of nearly four thousand prints and negatives that bring us face to face with the generation that settled the vast prairie lands of Nebraska. Since 1912 these images have been accessible, a prized part of the research collections of the Nebraska State Historical Society.

When photography was invented, young America was beginning to stretch into the new trans-Mississippi West, and within ten years of the revelation of Daguerre's successful photographic process in 1839, image makers were pressing onto the frontier. Few pictures from this early period have endured, and we can only imagine the vision of the fresh world found by those who first photographed the lands of the Louisiana Purchase.

With the end of the Civil War, America once again began its westward exodus, and the government launched exploratory surveys into the vast reaches of the frontier. Before the Civil War, most surveys were accompanied by artists who recorded what they saw with pencil and brush. In the postwar surveys, cumbersome photographic equipment replaced the sketch pad in capturing the breathtaking plains, deserts, and mountains of the West. As railroads cut across the plains and snaked into the mountains, they, too, took photographers with them, recording not only the progress of construction but also the land that the tracks crossed.

When, in 1869, the railroads completed the joining of East and West, the stage was set for a great experiment. Influenced by the Jeffersonian vision of a nation of yeoman farmers, Congress passed the Homestead Act of 1862 and the Timber Culture Act of 1874. This legislation, together with the sale at low prices by the railroads of the huge grants of land given them by the government, provided the means by which any settler could obtain a piece of land, a piece of the dream. The seductive advertisements of both the government and the railroads drew thousands west, offering a new promised land, a virtual garden of Eden.

Among the thousands who answered the siren call was Solomon D. Butcher. He was born in Virginia on January 24, 1856, the first child of Esther Ullom and Thomas Jefferson Butcher. In 1860 Solomon's father moved his family to Winona, Illinois, where he got a job with the Illinois Central Railroad pumping water for their locomotives. Young Butcher completed his high school education there in 1874 and for a time that year apprenticed to a tintypist and learned the art and science of photography.

In 1880 Butcher's father abandoned his secure job with the railroad to take a homestead in Custer County, Nebraska. Early in March 1880, accompanied by his father, his nineteen-year-old brother, and his brother-in-law, Solomon set out on the trek from Illinois to Nebraska, some seven hundred miles, in two covered wagons.

Seven weeks of travel ended when they arrived in northeastern Custer County, where Solomon and his father each took a claim. After determining that their claims had an adequate supply of water (an important concern on the prairie), they went to Grand Island, ninety miles southeast, to file for their properties in compliance with the Homestead Act.

When they returned to their claims, shelter became an immediate concern. Construction with sod (or Nebraska marble, as the locals called it) was not as simple as it might at first appear. The first trick was to locate the proper stand of grass that grew dense, dirt-holding root systems. A special breaking plow was used to cut the sod into long ribbons eighteen inches wide. These ribbons of sod were then cut again into three-foot lengths with a spade or corn knife, and the sections, three inches thick, were then laid like bricks to form walls. "My first experience in sod laying," reported Butcher, "con-

Posed in front of their sod house, a family of homesteaders faces Solomon Butcher's camera (1886). A family's possessions and livestock were as much a part of Butcher's images as the people themselves.

All photographs from the Solomon D. Butcher Collection, Nebraska State Historical Society.

sisted principally in wearing out my hands and my patience."

But Solomon rebelled at the thought of spending five years working a claim, as the Homestead Act required. After a two-week occupancy, he turned his land back to the government.

In the winter and spring of 1881–82 Butcher attended the newly formed Minnesota Medical College in Minneapolis. The experience did not result in a medical career, but it did introduce him to his wife-to-be, a young widow. Still restless, he returned with his bride to Nebraska. "I had seen just enough of the wild west," he later wrote, "to unfit me for living contentedly in the East."

Perhaps driven by the fear of returning to the physical life of farming, Butcher seized on an idea: he would produce a photographic history of Custer County. "From the time I thought of the plan," he said, "for seven days and seven nights it drove the sleep from my eyes."

But he had only the idea. His resources had long since been squandered in his moves and halfhearted attempts at homesteading. Butcher's father, however, had managed to make a comfortable life for himself. So Solomon asked his father for a team and wagon to transport the equipment necessary to make his photographs. His father was a "cautious man," and while the elder Butcher pondered the merits of the project, Solomon went to town and within two weeks arranged with seventy-five of the area's farmers to take their pictures for the history. This convincing initial response won both his father's blessing and the wagon, and thus supplied, Solomon began his enterprise.

Travel was complicated for Butcher; roads, if they existed at all, consisted of little more than ruts. He would journey for hours to reach the home of a family that he wished to photograph, and often he accepted food, lodging, and the stabling of his horses in exchange for a print. As he traveled, he supported himself with subscriptions and donations that various citizens made to the project, as well as by the sale of photographs. Over the next seven years he made some fifteen hundred images. Along with the photographs, he col-

Sod houses, built from the dense plains soil, were usually dark and cramped inside. In good weather, almost all activities took place outdoors. An extended family, left, lines up for a formal portrait, accompanied by their three mules (1888), and a group of men, below, engage in an open-air meal and card game (ca. 1886).

lected biographies and stories from the county's residents.

When it was finally published in 1901, the *Pioneer History of Custer County and Short Sketches of Early Days in Nebraska* ran for more than four hundred pages and contained eighty reminiscences illustrated with Butcher's photographs. The first edition of one thousand copies sold out before delivery that summer, and a second edition was ordered before Christmas. For once in his life Butcher tasted success.

Butcher's work has since become widely known. Scores of history texts have used his photographs of sod houses to illustrate the settlement of the Great Plains, and many of his pictures have made their way into books, films, and exhibits dealing with the American West.

S.D. Butcher has crept, almost anonymously, into the fundamental fabric of American thinking about the West. The fortunes of time and place were what created a number of the West's notable photographers. There were only so many government surveys and only so many railroads; fewer still were the number of photographers with a powerful aesthetic vision. It is therefore understandable why there were only a few William Henry Jacksons, Timothy O'Sullivans, and Carlton E. Watkins. But itinerant photographers like Butcher were common, for itinerancy was a fact of life for many western photographers.

Photography was not a lucrative profession. The economic fate of photographers was tied directly to the fortunes of the community in which they worked. If it rained and crops were good and prices up, people could afford photographs. If it was dry or crop prices were down, there was little interest in something as superfluous as a photograph.

Photographers facing these economic realities had limited choices. If the opportunity presented itself, they could also do contract work for the government, a railroad, or other major enterprises. Photographers could also try to produce pictures of interesting subjects that would sell outside their immediate market area, such as those of Indians, cowboys, or notable places or events. Another choice was to expand into fields such as pharmacy or patent medicine. The photographer could also go on the road and peddle portraits and other such images door to door. Most of these options forced photographers out of the studio and onto the road. Itinerancy was one method of breaking the downward economic cycle or at least forestalling it—a maneuver to extend the demand for photographic services.

Butcher's work has recently begun to capture the attention of art historians, and his photographs have been shown in prestigious museums and art galleries, but this is an alien environment for Butcher. Aesthetics was not a central concern for him, and anyone who has attempted to extract competent prints from his negatives will attest that he was not a technician of singular capability. Unquestionably he was not a prairie Stieglitz.

But if his method was not unique and his technical ability was merely adequate, how is it that his work has become so well known and widely used? It is significant

The subject range of the itinerant photographer was vast. Butcher might capture a gentleman out for a drive in his new car (1911) or take a humorously staged photograph on a Nebraska ranch (1903).

that Butcher was not primarily a portraitist. Because he was interested more in the settler's way of life than in the settler, he tended to step back and shoot whole homesteads. For him the house and possessions were equal in importance to the homesteaders themselves. In some of his photographs, in fact, the people in the picture are so small as to be rendered almost insignificant. What his pictures really deal with are states of existence. The houses and personal possessions serve as more than mere studio props. They are narrative elements that make a conscious statement by both the photographer and his subjects about the life that the subjects were living.

In my mind the significance of Butcher's work, then, is to be found in the statement that the photographer and the subjects make. There is a pride here that comes not from the accumulation of wealth but rather from being a part of history in the making. These people—the ones who came to settle the plains—came for land, to farm and ranch, to live that noble yeoman existence that Jefferson heralded.

I think Solomon Butcher was steeped in that significance. Certainly he knew of and revered Jefferson and his ideas, having been born in Jefferson's home state, the son of a man named for Jefferson. Moreover, he knew from intimate experience what the yeoman life meant, what the real worth of land was.

Some have looked at Butcher's work and seen in it lives of privation and suffering. It is, I think, because we like to make pioneers and settlers more than human, facing and overcoming all odds of man and nature. Perhaps there is a kind of severity that plains life etches into the faces of its people, but Butcher's people were, for the most part, neither hard nor in a state of suffering. Life may not have been easy, but neither was it desperate. These are not the faces of shattered lives, as pictured by Butcher's contemporary Jacob Riis; rather they are faces of hope, determination, and accomplishment.

In 1932 Jules Haumont, nephew of Gideon and Isadore Haumont, the men who built a palatial two-story sod house that Butcher photographed, said:

We came here to this beautiful country, in those early days, young, strong, healthy, filled with hope, energy and ambition. Poor, it is true, Oh! how poor in worldly goods, but rich beyond dreams, in everything that makes life worthwhile. I do not know how large a bank account some of the old settlers may have today, I do not care, they will never be as rich as I felt when I first settled on my homestead. I remember the time I did not have the money to buy a postage stamp. I remember the hard winter, the drought of 1894, the many obstacles to overcome. We came to win the battle, and

we did. To what amounted those inconveniences, compared to the joy we felt, when we turned the long furrows of virgin sod, or planted our first fruit trees. We were empire builders. The future was ours.

Because many of the pictures that Butcher made were more than portraits, a unique interaction resulted between photographer and subject. Images appear to have been set purposely like a stage. The subjects seem to assume stances that are symbolic and expressive. Some appear with jaw set and shoulders back; others with sweeping, master-of-all-you-survey gestures. In some instances people dragged their most precious possessions out to be photographed with them or rearranged equipment and livestock to be a significant part of the image. But this hauling out of prized possessions was not done as often as some have assumed. Sod house dwellers were fundamentally people who lived out of doors. A sod house was a shelter while they slept, a haven from storm, and a place to cook in the winter. The standard litany recited about sod houses is that they were warm in the winter and cool in the summer—and that is true, owing to their three-foot-thick earthen walls. But they were also dark and usually cramped. So when the weather permitted, almost all living activities took place outside. Many items, such as chairs, sewing machines, and stoves, normally associated with indoor activities, are found outside in the Butcher photographs. When the sod house era had passed, so too had this need for outdoor living. In his later photographs, which show frame structures, the clutter of outdoor living disappears.

The history that Butcher recorded was personal—one of individuals and not movements. Only one in three homesteaders stayed the five years required to prove up on their claims, and many of those who proved up would be forced out by later adversity. Therefore, each homesteading ex-

perience was an individual drama. The pride of survival is evident in the faces of Butcher's subjects; their gaze is arresting and their expressions electric with hope. Like other nineteenth-century photographers, Butcher engages his subjects directly. They face the camera squarely, photographed not in the act of doing but rather in a state of being.

In many of Butcher's photographs, people appear barely visible in doorways and windows or they stand so far in the background as to be hardly noticeable. In this way Butcher would often pepper his photographs with people, seemingly scattering them about the frame. This curious spatial arrangement tempts one to speculation. The proximity of person to person may be tied to kinship, with members of the nuclear family massed together and extended family members or hired help projected out elsewhere. It might be that such groupings are the result of subjects posing themselves (although that is unlikely, for only the photographer would know the scene's organization as the camera sees it). More than likely, however, these groupings are the result of Butcher's own eccentric aesthetic, combined informally with the desires of his subjects.

In most of his landscapes (of which there are few) Butcher placed a person somewhere in the distance. Perhaps he did so to indicate scale or to include a human element in the pictures that he made of the land, much as he put the land in the pictures that he made of people.

The interaction of human subject and the land bears close examination in Butcher's work. As a whole the collection reveals a great deal about the process of settlement—far more than the photographer had likely intended. This process is almost an evolutionary one: of people marking the land, dividing it. "Of all the bewildering things about a new country," wrote Willa Cather in *O Pioneers!* "the absence of human landmarks is one of the most depressing and disheartening . . . ."

It is here in a bewildering new country that the settlement odyssey begins. The first sod houses divided only the inside from outside. With typical eloquence Cather describes them as "only the unescapable ground in another form." In these preliminary dwellings people and animals share quarters; work areas are indistinguishable from living areas. Soon one witnesses the cropland becoming more distinct and living and working areas more defined. Fences segregate animals from humans, and outbuildings more sharply focus the various labors of agriculture. With the frame houses come yards and ornamental gardens, and the differentiation begins to move indoors. The frame dwelling offers more than the shelter afforded by sod houses, for it can provide privacy and an interior division of labor. Spaces within the house are dedicated to specific activities: eating, sleeping, socializing, and even storage.

With but little imagination we can see the process as one of bringing the horizons closer. From the collective level, that is what the legal division of land did, sectioning a continent into 100-mile-squares, and those into 160-acre, quarter-mile squares. Inside these quarter-mile squares individuals begin to define inside from out, animal habitation from human, working land from living space, and space inside the house itself. It seems a process of putting boxes in boxes, the "record of human strivings" to which Cather referred.

There is a sense of humor and a lack of preciousness in Butcher's photographs that I find refreshing, and yet these very qualities may exclude him from serious consideration by art historians. I suppose that it is just as well, for Butcher himself would be uncomfortable in such a company as that.

He really was just an average sort of fellow—a dreamer at that. We can, however, thank him for having the common sense to see the obvious. I often wonder whether, if he were alive today, he would be photographing mobile homes and fast-food restaurants. It is that kind of vision for which history, in hindsight, is grateful. "How well I have succeeded," he said in his *Pioneer History of Custer County*, "I will leave to the reader to judge after he has read to the last page and looked at the last picture, and hope you will always hold in kindly remembrance your humble servant S.D. Butcher." □

A settlement odyssey begins. The Reverend Peter Widvey, his wife, children, dogs, chickens, and mules pose below the unfinished sod house that was to be their home (1887). When Butcher took this photograph, the family was living in the little dugout visible in the upper lefthand corner.

The first Subaru
designed to
accelerate your
pulse rate.
Seat belts save lives.

Subaru humbly introduces a car that will knock your socks off.

The 1985 Subaru XT Coupe.

A car whose combination of styling, technology and interior features is not only new, but unique among today's cars.

Starting from the ground up, we took the best inherent qualities associated with Subaru and combined them with our latest, most advanced technologies. And they include everything from a self adjusting air suspension system most commonly found on jets to front wheel drive with 5-speed turbo.

The result is a car that lets you control roads, hug curves and plow through snow, all the while surrounding you in the most luxurious creature comforts.

From the outside, the most innovative aspect of the Subaru XT Coupe is its styling. And yet the term styling is one that hardly does justice to this exterior.

The Subaru XT Coupe is one of the most aerodynamic production cars in the world. Its astoundingly low drag coefficient is achieved with a low slanting hood, concealed headlamps, flush roof pillars and door handles, and a smooth flowing roofline, to mention just the most obvious contributors.

The only car of its kind with an "On Demand"™ four wheel drive system.

No other sporty car offers you the choice of the following technologies: front wheel drive, front wheel drive turbo, and Turbo Traction.™

In plain English, our "On Demand" four wheel drive transmission lets you switch from front wheel drive to four wheel drive instantly and without stopping. Turbo Traction combines Subaru's proven "On Demand" four wheel drive system with the power of a 1.8 litre fuel injected water cooled turbo.

And when the talk shifts to engines, the XT Coupe really takes off.

Because it's the most powerful, most performance oriented car Subaru has ever engineered.

And if that's not enough, you can combine any Subaru engine with either a 5-speed manual or 3-speed automatic transmission.

To call the Subaru XT Coupe unique in its class would be inaccurate. It creates an entirely new class of its own.

The interior is as advanced as the exterior.

From the all new adjustable sports seats with high side bolsters for lateral support, to the soft grip telescopic tilt steering wheel with moving instrument panel, this interior has been designed to make you feel a world away from the world outside.

Its "fingertip close" instrument pods put vital controls within easy reach. And the unique video monitor easily provides important engine information at a single glance. But they're only part of a state-of-the-art display of information for which the word "dashboard" is barely adequate.

In fact, once inside you'll notice that the XT Coupe bears no resemblance to any previous Subaru. Or, for that matter, any other car.

An untraditional car born out of traditional values.

The 1985 Subaru XT Coupe is available in four versions. DL, GL, and the extra luxurious front wheel drive GL-10 Turbo, and GL-10 4WD Turbo.

All of them, however, have one important thing in common. They're all Subaru. Which means no matter how technologically advanced and luxurious, they're all true to the Subaru tradition of building the world's most dependable cars at an affordable price.

In fact, according to a recent survey by an independent research firm*, Subaru was ranked second only to Mercedes Benz in customer satisfaction. Better than Toyota, Honda, Nissan, Mazda, BMW, or any car by GM, Ford or Chrysler.

What's more, many Subaru dealers also offer Added Security.® The only extended service contract backed directly by Subaru.

The 1985 Subaru XT Coupe.

It's everything Subaru has always been. And everything it's never been.

THE 1985 SUBARU®

Inexpensive. And built to stay that way.

*J.D. Power and Associates Customer Satisfaction Index 1984 Survey of 1983 Model Year Car Buyers with 12-14 months ownership experience.

A Movable Feaster

A tiny, caterpillar-like carnivore has survived since all the continents were one

by Michael T. Ghiselin

In 1826 Rev. Lansdown Guilding published a description of a curious little animal from the Caribbean island of Saint Vincent. To him, it looked rather like a slug, but it was a most peculiar one, with many little feet. He named it *Peripatus juliformis* and created a new class of mollusks to receive it. This obscure creature has been the subject of scientific inquiry and debate ever since.

To most people, *Peripatus* looks more like a caterpillar or a centipede than a snail or a slug. Pre-Darwinian zoologists agreed that the resemblance to mollusks was superficial. Their evolutionist successors recognized the creature as a very primitive arthropod, illustrative of the early stages of adaptation to life on land and suggesting links between major animal groups. Peripatuses and their allies came to be classified as a distinct group called the Onychophora, a name that refers to the claws on their feet.

Today, they still occasionally provoke taxonomic controversy. Onychophora is sometimes treated as a separate phylum, sometimes as part of the Arthropoda (along with insects, crustaceans, and spiders). There is little doubt the phyla are related, but it is still being debated whether the onychophorans are closest to insects and centipedes or whether they branched off from the mainstream of arthropod evolution somewhat earlier. Fossils are of little use in deciding this issue; as with soft-bodied organisms in general, remains are few and hard to interpret.

Our growing understanding of continental drift in recent decades confirms the idea that the onychophorans are very old. The thirty or so known species fall into two natural groups. One group, which includes the genus *Peripatus* itself, occurs in tropical America, the Congo, and within and around the Malay Peninsula. The other group inhabits Chile, South Africa, New Zealand, Australia, and New Guinea. Since onychophorans can't swim across oceans, these two discrete groups must have evolved before the ancient supercontinent of Gondwanaland broke up. Even before that time a desert seems to have separated the northern and southern forms. Then, when the huge landmass

Photographs by Raymond A. Mendez

Peripatuses capture prey by shooting a gluey substance from openings on each side of the mouth. Below: After firing its glue, a collared peripatus draws back its head to break the sticky threads. Wartlike papillae, each with a sensory bristle, ring the animal's body and legs.

A collared peripatus closes in on a cricket, a favored prey item. Crickets are more agile than the slow-moving peripatus, but they are helpless against the predator's glue.

came apart, peripatuses drifted with the fragments, sometimes to within crawling distance of new habitats.

In the late nineteenth and early twentieth century, peripatuses and their relatives were very popular objects for evolutionary research. These animals were an old form of life, yet their anatomy seemed to have evolved very little. Indeed, for more than a century, they, along with the lungfishes and egg-laying mammals, have been viewed as living fossils. And because they have some characteristics of segmented worms and some of arthropods, they are one of the best cases of a transitional form, or nonmissing link.

For example, the peripatus's eye, at the base of each antenna, is more like the simple eye of a worm than the compound eye of an insect. Like higher arthropods, the peripatus has limbs, but these do not have

Stalking the Collared Peripatus

by Morley Read

When darkness falls, I set off through dense forest to my study site, a steep earthen embankment about 130 feet long. Offering numerous holes for daytime retreat, the bank is prime peripatus habitat. I scan the slope with my headlight; the night forest is alive with the sound and movement of bats, crickets, and frogs. Occasionally I glance at the path ahead to avoid an encounter with a fer-de-lance, one of the most venomous snakes in the area. For the past two years, I have studied peripatus nocturnal habits at the Simla Research Station in Trinidad, home of the largest species, the collared, or giant, peripatus (*Macroperipatus torquatus*). Its length (up to six inches), dark red body, and bright yellow collar make this species somewhat more conspicuous than its plain and equally reclusive relatives.

After an hour's search at the site, I spot the caterpillar-like animal trundling over the soil, its stumpy feet propelling it several inches a minute. The double claw on each foot enables the animal to grip and climb vertical surfaces. On an average night, one or two collared peripatuses will be visible, out of a population of about thirty—half of them adult females; the remainder, adult males and juveniles. Many simply stay in their burrows. Those that do emerge are usually well concealed by leaf litter and other damp forest detritus.

Although capable of walking many yards in a night, adult females maintain home ranges of a few square feet centered on one or more favorite burrows. Males, smaller and with fewer legs, roam in search of food and mating opportunities.

My study focuses on the feeding behavior of the collared peripatus. Witnessing a capture repays many long nights of watching. A carnivore, whose diet includes crickets, spiders, cockroaches, and assorted microfauna, the collared peripatus often attacks prey as large as, and nimbler than, itself. The first feeding I observed pitted the peripatus against a delectable but agile long-legged black cricket, *Aclodes*.

Whether lurking at burrow's edge or venturing out to hunt actively, the collared peripatus detects nearby prey by touch and smell. The creature's typical sluggishness now serves as stealth, and its dramatic defensive maneuver, shooting strands of glue from openings near the mouth, is put to aggressive use. At times when its approach is entirely undetected, the peripatus examines a potential victim with its antennae and sometimes rejects it. Glue is mainly protein, and its expenditure on overly large prey likely to escape or on tiny prey that yield little nutritional return is presumably not cost-efficient for the peripatus.

Glue squirting is instantaneous. Suddenly a cricket is lassoed with lengths of sticky thread. Struggling all but guarantees entrapment, as the prey's legs stick together, but if the victim continues to kick, a few small squirts will suffice to glue down any flailing appendages. (Twice as much glue is needed to disarm a fanged spider as for a cricket of similar size. In one case I observed, this tactic failed, and an exceptionally big spider ate the peripatus.)

With the prey safely subdued, the dining ritual begins. Using its spiky jaws, the peripatus repeatedly bites and pierces a soft spot in the prey's body and injects a potent saliva that, within ten to fifteen minutes, kills the cricket and renders its inner body soft and palatable. During the waiting period, the peripatus gobbles up as much expended glue as it can to regain valuable protein. When the feast is ready, the peripatus dismantles the cricket, methodically tearing apart the hard abdominal plates and extracting strands of flesh with a ratchetlike jaw action. Several phalangids, relatives of the spiders and the "hyenas" of the jungle floor, gather, eager to steal a piece of the kill. In several hours, only the cricket's exoskeleton remains, and the collared peripatus is satiated for another two weeks. By dawn, all traces of the encounter have been erased by scavengers.

Working its jaws into a soft spot between two of the cricket's thoracic plates, the peripatus pours in its lethal saliva. Within fifteen minutes, the potent injection kills the cricket and begins to dissolve its inner flesh.

Having pulled away the cricket's abdominal plates, the peripatus delves into the body to feed on the softened contents.

the characteristic joints of the limbs of hard-bodied insects. Most of the body of the peripatus is wormlike, being soft and flexible, but the beginnings of a hard exoskeleton—like that encasing the whole body of higher arthropods—is found in the paired claws on the tips of its feet. Its soft body, incidentally, permits the peripatus to maneuver adeptly under stones and leaves or through cracks into rotting wood, in search of moist places. Otherwise it would dry out.

Because it has so many transitional features, the peripatus is a good subject for studying how one group of organisms evolves into another. One pair of limbs has been modified into jaws, and the hard tips have become enlarged claws. Another pair of limbs, near its mouth, has been modified into an organ that can shoot a sticky substance as far away as six inches. The animal uses the glue— produced by a modified kidney—for defense and to capture small animals for food. This example illustrates how a new organ, such as the animal's glue producer, does not arise out of nowhere but evolves from a preexisting organ that is in the right place and is able to shift to a new function.

If there were a Hall of Fame for life forms, perhaps the thirty odd species of peripatuses and their relatives would be retired to rest on their many scientific laurels. But contemporary biologists are raising many new kinds of evolutionary questions about the onychophorans, especially about their reproduction.

Onychophorans may be living fossils, but they have evolved a range of internal reproductive systems that at one extreme are like those of a lizard; at the other, resemble those of higher mammals. Some onychophorans bear young that develop internally; others still lay eggs. At the most primitive end of the onychophoran reproductive scale, *Ooperipatus* lays shelled, yolk-rich eggs, which develop outside the mother's body. Interestingly, like the egg-laying mammals, *Ooperipatus* is found in Australia. Taken all in all, the various types of onychophorans form an evolutionary series in which the embryo comes to be nourished less and less by yolk and more by secretions from the mother. In the most advanced mode of reproduction, found in peripatuses and their close relatives, a tiny egg attaches to the uterine wall and forms a true placenta—an arrangement similiar to that of higher mammals. This is a remarkable case of convergent evolution.

In some onychophorans, gestation is very long—twelve to fifteen months is not unusual. Often the uterus contains a series

Peripatuses lose both energy and body weight when they expend glue. While the saliva is acting on the prey, the peripatus salvages protein by eating any used glue that it can recover.

Although peripatuses evolved millions of years before placental mammals, some species bear live young. Below: By contracting its body, a young peripatus has almost completely freed itself from the mother's genital orifice (at top). Right: Although there is no evidence of parental care, newborns usually remain with the mother for several days. Young are able to walk and eject glue immediately after birth.

of developing embryos of different ages. Females begin to reproduce long before they reach full size, and a large proportion of their bulk consists of developing young. Therefore these animals have evolved an elaborate system of prenatal care, without having changed much otherwise. The reason why this "living fossil" has been so conservative in most aspects of its ecology remains unknown, but the variety of its reproductive modes can be explained in ecological terms. The placental forms are found in tropical areas, where the climate is stable and the food supply relatively constant. Under these conditions, parent organisms can consistently provide offspring with food and can successfully raise young throughout the year. Egg-laying forms are found in temperate regions with markedly different seasons. Here, a parent may be more successful if it raises a whole clutch at once, during the limited time that food is plentiful.

Another interesting question, also related to reproduction, is the evolution of sexual dimorphism. In most onychophorans, females are considerably larger than males. One explanation may be that large females are more successful at reproduction, but perhaps small males are better at becoming fathers. In evolutionary theory, reproductive success relative to other members of one's species is all that matters. In other words, whatever helps an organism outreproduce its conspecifics will evolve in the long run.

For an animal that moves like the peripatus, the larger it is the more legs it needs (just as large trucks need more wheels). A comparison of various species of onychophorans reveals that the biggest animals tend to have the most feet. Both males and females are about the same size when born, but in species in which females are larger than males, females have more legs from birth. All this is indirect evidence that females have evolved a larger body relative to males. Large size allows females to carry more offspring. (Onychophorans are born rather large. In one study, a half-grown female already contained young ready to be born; these were half her body length.)

But what about the small males? The male contributes nothing but sperm to reproduction. Most often, he places a packet of sperm in the female's reproductive opening. In some South African onychophorans, the male injects sperm through the female's body wall into her bloodstream. In either case, the sperm accumulate in a storage organ and are kept until needed. One impregnation may suffice for the female's lifetime. With such an arrangement, the best way for a male peripatus to reproduce is to mate as soon as possible and not waste time growing. If he dies after mating, his sperm live on in the female. Indeed, male onychophorans are sexually precocious, and some may even be fertile at birth.

Something more must be going on with the small male, however; a larger male that lived longer could produce more sperm and copulate more often. There may be other advantages to being small. Perhaps the small male can crawl more easily among leaves and under stones to find a mate or a moist spot or to avoid a predator. An adequate treatment of the question of smaller males will probably involve a complex balance among the advantages and disadvantages of a given size in feeding, growing, surviving, reproducing, and other activities.

A relationship between size and reproductive strategy can be seen in other animals. Some actually change sex as they grow older, sometimes from male to female or vice versa. In a fair range of animals, the young start off as males and produce sperm. But when they grow large enough to make an adequate supply of eggs, they become females. In other animals, males monopolize mates by fighting. Various fishes begin and grow as females until they get big enough to win fights. Then they switch sex. The same basic principles apply to peripatuses, but instead of changing sex, males mature early and remain small, while females mature later and grow more. A similar pattern has been discovered in the viviparous surfperches of California. The young are born relatively large, and males, which are much smaller than females, are able to father offspring soon after birth.

Naturalists have been observing such peculiarities of reproduction for many years. Often they have been recorded as mere curiosities or attributed vaguely to some advantage for the species. With modern "sex-allocation theory," evolutionary biologists can explain such facts in terms of a few basic principles that apply to all organisms. Peripatus may be an exotic creature, but the truths that it exemplifies cast light on all the rest. □

Hungry for sugar, ants hover around a treehopper trio. Treehoppers feed on phloem sap and excrete sugary honeydew; ants tend them in order to collect it.

A. Wilkinson; Valan Photos

Sugar Nannies

What's good for honeydew-hooked ants is good for sugar-excreting treehoppers

by Catherine M. Bristow

J.H. Comstock, one of the leading figures in American entomology, once wrote, "Nature must have been in a joking mood when she made the treehoppers." Treehoppers—so called because most types feed on trees or shrubs, from which they launch themselves abruptly if disturbed—certainly are curious. Some look just like thorns. Others look like cartoon monsters from outer space. Many of them have weird-looking, overdeveloped pronotums, the structure that covers an insect's chest or shoulder region. Of course, not all treehoppers are striking. But even relatively drab species such as the ironweed treehopper, *Publilia reticulata,* have a remarkably rich repertoire of behaviors, many of which stem from their propensity to enter into alliances with other insects.

Many insects, including treehoppers, are commonly tended by ants. "Ant cattle" was the term Linnaeus used to describe them in 1766, and the behavior of ants around these herds has fascinated several generations of naturalists. The ants, and in the temperate zone this includes many species, seem almost nurturing: they patrol the area around their chattel for up to several hours at a time, aggressively driving off intruders and sometimes carrying the insects to better feeding spots. They often build small shelters over them to keep them dry during rainy weather. Ants have even been known to protect the eggs of some insects by storing them in their own nests during the winter. What do the ants get out of it? Mainly, access to sugar—which is continually excreted by treehoppers, aphids, and the other insects ants tend.

Casual observers of this phenomenon usually notice the ants, and from that perspective, treehoppers and other ant-tended creatures do seem like docile herds that are exploited at the whim of their masters. But recent studies, by myself and others, indicate that this is not entirely the case. Treehoppers have developed ways of exploiting ants in return, improving on the standard benefits. This reciprocal exchange of services between two species is called a mutualism. And the mutualism between ants and treehoppers is one of the most intriguing examples of cooperation in nature.

Ironweed treehoppers belong to the insect order Homoptera, which includes most other ant-tended insects such as aphids, scale insects, and mealybugs. All homopterans have mouthparts designed for piercing plant tissues and sucking up the juices. Although different species feed on different plant tissues, most of those that attract ants feed on phloem sap. Phloem is one of the plant's vascular tissues and is its pipeline for transporting nutrients from leaves to roots or flowers. The sap contains primarily sugars and also some amino acids. So while it supplies more than enough carbohydrates to meet a treehopper's growth requirements, it doesn't provide much nitrogen, found in protein or amino acids, which all animals need to build tissues and carry out many other physiological functions. Treehoppers overcome this problem with a strategy that's not particularly efficient but very workable: they simply eat more sap. This allows them to take in the requisite nitrogen and then excrete the extra sugar—along with water and traces of other compounds—as honeydew.

Phloem sap, the basis of maple syrup, can be very sweet. Even after being digested by treehoppers, it is usually 10 to 20 percent sugar. As a result, honeydew is a valuable food to many animals. Bees sometimes collect it instead of nectar and make honey out of it. Even humans have collected honeydew for food: the manna of the Old Testament may have been dried honeydew, and today people still gather *man*, or sugar lerp, in several parts of the world. Ants, however, are undoubtedly the keenest collectors of honeydew.

How do these sugar aficionados operate? An ant will approach a treehopper and stroke the insect's back end with its antennae. If the treehopper has any honeydew, it will usually respond to this stimulation by excreting a droplet, which the ant takes in its mandibles. The ant normally stores the liquid in its crop, an expandable storage organ. Usually an ant worker will continue "milking" treehopper nymphs until its crop is full. Then it returns to the nest and freely passes the honeydew to other ants.

However renewable or defendable this food source may be, ants don't get a free lunch. Ironweeds, and other treehoppers, do their feeding at host plants, and if they want honeydew, ants have to make a trip there. This means some time and energy must be expended in travel from the nest to the feeding site. Also, since treehoppers allow other animals to feed on their wastes, ants may have to spend time defending the resource. I have seen ants aggressively attack other insects that approached their sugar cattle. Most of the time this involved ants from other colonies, which were after some honeydew themselves, but it can also include predatory insects such as ladybugs. (An individual ant may be able to repulse an intruder on its own. However, an ant generally sounds an alarm in situations like these—secreting a pheromone that mobilizes nest mates. So it soon has help.)

Traveling to a food source and defending it take time and energy, and a number

Food is the main reward ants get from associating with treehoppers, but the latter receive a wide range of benefits. If ironweed treehopper mothers can attract ants to their nymphs, they can abandon the clutch early and go on to lay more eggs. The mother below is remaining with her eggs in an attempt to lure the formicine ants next to her to begin tending her young.

Raymond A. Mendez

of variables influence whether an ant colony will find it worthwhile to work a particular group of treehoppers. For example, the size of a treehopper colony (in this case, colony means the nymphs of one mother) and its distance from the ants' home nest are important considerations. So too are the nutritional needs of a particular ant colony. Energy foods like sugar may be able to sustain workers, but ant larvae need protein. Honeydew may be less important to a colony at certain times than carrion, small insects, or seeds.

As a result, ants modify their foraging behavior depending on circumstances. They may abandon treehopper colonies that are too small or too far away. Species of larger ants may also have standards different from those of smaller ants of what makes a treehopper colony worth exploiting. Generally, larger ants are pickier than smaller ones about getting bigger colonies of treehoppers and more sugar.

But ants have very little in the way of specialized adaptations that keep the mutualism going. Even something that might seem like an obvious adaptation—building shelters for their insect stock, for example–is less for the treehoppers than for themselves. A few ant species form permanent trails to trees that support large populations of sugar producers. But most ants are more opportunistic than this. Indeed, their main concession to their partners is that they rarely eat them!

For treehoppers, it's another case entirely. The benefits provided by the ants are much more important to their success, and they have invested much more in maintaining the association. The ironweed treehopper is a good example. I spent several summers studying this species in an old field in New Jersey, tracking the new generation of nymphs for the six to eight weeks of their development. The field is actually a farm that was abandoned thirty years ago, and the main plants growing there now are goldenrod, brambles, and wild rosebushes. But down in the wet meadows and around a local pond we find dense patches of ironweed plants (*Vernonia noveboracensis L.*), some of which have gotten to be six feet high.

Ironweed treehoppers develop into adults their first year and overwinter in hibernacula at the roots or bases of plants. When they emerge in May they move about, presumably searching for mates and feeding plants. They mate on the feeding plants, and the males disappear shortly after that. The females then begin laying their eggs.

Both the mothers and their offspring, I learned, receive several different kinds of benefits from ant attendants. The most important of these is protection of the young from natural enemies, for without ants young treehoppers are essentially defenseless—they can't run away or protect themselves. Indeed, even with ant protection, many fall prey to spiders and ladybugs. Tended by ants, about twelve treehoppers will survive out of fifty, the average size of an egg mass. Without ants, the survival rate is only about 5 to 10 percent. In a world that measures success in terms of the number of copies of genes an animal passes on to the next generation, this difference can be very important.

Young ironweed treehoppers gain two

Ants of the species Ectatoma tuberculatum *watch over, and milk, a herd of treehoppers in Trinidad. To collect honeydew, an ant approaches the nymph and strokes its back end with antennae. The treehopper may then excrete a drop of honeydew, which it holds in place until the ant takes it in its mandibles. Ants generally store food in their crops and share it at the nest.*

Raymond A. Mendez

other rather surprising advantages from ant care. First, they grow to be larger adults. And, unexpectedly, some ants enhance growth more than others. Nymphs tended by *Myrmica lobicornis fracticornis* and *M. americana*, both medium-sized ants, are 20 percent larger than untended nymphs by the time they become adults. By contrast, nymphs tended by *Tapinoma sessile*, a much smaller ant, end up only about 10 percent larger than their untended counterparts. Tended nymphs also develop faster. Again, *Myrmica* ants are more effective at speeding things up. They cut almost ten days off the normal fifty-day development period. We still don't know why ants should have this effect, but we speculate that the treehoppers may develop faster because they tend to spend more time on the tops of leaves when ants are around. This means they're out in the sun for longer periods, and Tim Casey, a researcher at Rutgers University, has suggested this could influence growth.

Whatever the reasons, it seems clear that treehoppers with ant guardians have an array of advantages over those without them. Quicker development for a nymph means it spends less time vulnerable to the vagaries of the weather or to marauding predators. And bigger individuals have a competitive edge. In most invertebrates, the female's adult size is directly proportional to her fecundity—or the number of eggs she can produce. Large individuals may also have a better chance to survive the winter, to avoid predators, and to obtain mates. And finally, since larger treehoppers produce more honeydew, they may be able to attract the largest and best ants to tend their young. Although these

A group of formicine ants converge on a ladybug that has come to prey on their ironweed treehopper stock. At a study site in New Jersey, ironweed treehoppers that were protected by ants had a higher survival rate and grew to be 20 percent bigger than nymphs with no care.

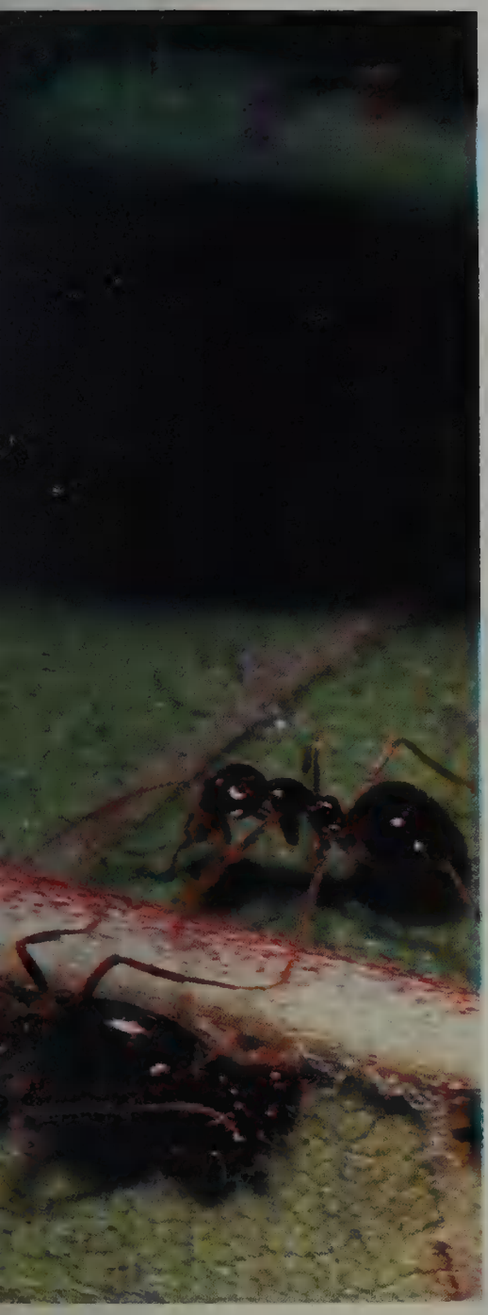
Raymond A. Mendez

patterns seem to apply to *Publilia reticulata*, we will have to test them directly to know for sure.

Why ironweed treehoppers do better under the attentions of one ant than another also remains unknown. We know that ants can increase the growth and fecundity of aphids, probably by causing them to increase their feeding rate. A similar mechanism may be operating for the treehoppers. In any case, all of these differential benefits mean that treehoppers must not only have adaptations to insure ant attendants but they must also try to attract the best ants. This, I have found, is exactly what they do.

Obviously, the best way for treehoppers to draw in ants would be to increase their output of sugar. They do this primarily by aggregation, or living in groups. The first opportunity for aggregation comes early in the reproductive season, when females are choosing ironweed plants on which to lay their eggs. Females can be quite picky at this time, selecting only the largest and most vigorous stems. Using some cues that we do not yet understand, they will often congregate on stems, and many plants end up supporting two or even three colonies of treehoppers while others have none.

Such aggregation of colonies is the first step toward increasing the density of honeydew producers and thus the overall crop. Another strategy females use is to put all their eggs into one basket. Most female insects hedge their bets by laying their eggs over a variety of suitable sites. This not only reduces potential competition between offspring but also reduces the risk that all the young will fall prey to some calamity such as a predator destroy-



ng the entire colony or a large animal damaging the feeding plant.

Female treehoppers, however, generally deposit a single clutch of about fifty eggs in the midrib of a leaf. Laying such a large clutch guarantees that all the young nymphs will at least start their lives as members of a group.

The young nymphs also behave in a highly gregarious way. Newly hatched treehoppers are only about a millimeter long and are not capable of moving about to any great extent. As they grow, they normally pass through five molts, each stage being larger and more mobile than the last. By the third stage, or instar, nymphs are able to move to adjacent leaves. This reduces competition among them, for a single leaf would never be able to support all fifty nymphs through their six- or seven-week development period. But even though they are spread out all over the plant, the nymphs remain gregarious, usually feeding in groups ranging from a minimum of three, up to fifteen.

The instinct to remain with family members is very strong. An individual nymph can be marked and moved to another suitable plant about three feet away—a considerable distance to a creature that measures only about a quarter of an inch in length. Yet within twenty-four hours, the marked youngster will be back in the midst of its brothers and sisters.

A group undoubtedly serves to attract ants, since more treehoppers produce more honeydew. And the young treehoppers behave as if they recognize this basic principle. When attendants are present, the nymphs will eventually spread out over several leaves. But if ants are excluded from a dispersed colony, the young treehoppers will immediately reaggregate into one or two large clusters.

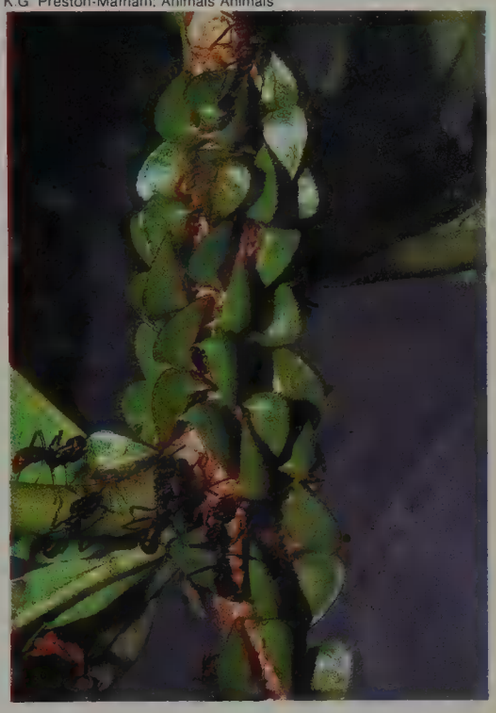
Another method ironweed treehopper mothers use to lure ants is to remain with their eggs after they are laid and even after they are hatched. This sort of maternal care is unusual for insects, except among the true social insects (for example, bees, ants, or termites). Why does a female remain? There appear to be two reasons.

The first reason is the obvious one—she is there to protect the eggs. Although ironweed treehopper females are not well equipped to deter large or determined predators, they do kick sharply at any intruders. A mother's care, when no ants are present, increases the survival of young from 3 to about 10 percent. This is still considerably lower than the 25 percent that survive under the protection of ants.

The other reason for staying is that a large female produces considerable honeydew in her own right and may attract ants during the period when the young themselves are not able to attract their own bodyguards—that is, before the eggs

Sensing a rich source of sugar, ants swarm onto a dense cluster of treehoppers in Trinidad. Treehoppers often aggregate, possibly to concentrate their total sugar output and make themselves more valuable to ants.

K.G. Preston-Mafham, Animals Animals



hatch, and when the young treehoppers are very small. Colonies that start out with a female in residence, I have found, are far more likely to be protected by ants throughout their development.

Females even seem to time their reproduction so they can attract preferred ants. Because ironweed treehoppers overwinter as adults they get an early start on their families and a longer growth season. But a second benefit is that the appearance of early colonies in June coincides with the period of peak activity of larger ants such as the two *Myrmica* species. These ants are, in general, more tolerant of cool temperatures; and by timing her oviposition to fall at this time, a female more than doubles the chances that her brood will be guarded by the best ants possible.

The adaptations that these treehoppers have evolved to attract ants are remarkable. However, there is more to the story, for ironweed females have developed the ability to modify their behavior to take full advantage of the surrogate mothering provided by ants.

Ironweed females are actually capable of producing several fifty-egg clutches, so in staying to care for the first one they are making a sacrifice. This cost is offset by the increased survival of the young. If ants

E. S. Ross

Aphids and scale insects, which also produce honeydew, are other insects with which ants form mutualistic relationships. The worker ant below is presiding over a batch of aphids, one of which is presenting its rear end—the classic posture prior to the excretion of a honeydew droplet. Treehoppers in the temperate zone are often dull looking, but tropical types are a wild collection of creatures. The group of spiny Guatemalan treehoppers, right, are sucking phloem sap.

Dwight R. Kuhn

are present to take up parental responsibility, however, the young will be adequately cared for and the female can depart. Indeed, this is what I have found she does. If no ants are present, the female ironweed treehopper remains with her young as long as any survive—on average, slightly more than a month. When ants are there, however, she abandons her offspring about six days after hatching begins. Thus females remain only long enough to insure ant attendance through the period when the young are not producing enough honeydew to attract ants themselves.

But what benefit does a female gain from desertion? Mainly she gains another chance to reproduce, for females that let the ants take over maternal chores go on to a new site and lay a second clutch of eggs.

For second, as for first, broods, females must balance the trade-offs between making the eggs attractive to ants and avoiding the danger of putting all their eggs in one place. Females achieve this by adopting a mixed strategy. About half lay their second clutch on another leaf of the same plant. This seems to happen particularly if they are not sharing the plant with any other mothers. The other half of the females move on to a new ironweed plant.

Producing a second brood on the same plant has inherent drawbacks, for it is the ultimate case of putting all your eggs in one basket. But there are several advantages, too; besides eliminating the uncertainty of finding another suitable feeding plant, the female gets automatic care for her second clutch. This is because the ants already caring for her first brood patrol the entire stem, and thus provide a ready-made protection service for the new clutch. And the females know this instinctively, for, as my studies have shown, rather than waiting until the nymphs are a week old, they desert these second clutches six days *before* hatching begins.

If the female moves onto a new plant to lay her second clutch she is essentially starting from scratch. And, once again, she behaves with fitting maternal solicitude—remaining with the newly hatched nymphs for more than a month if she fails to attract ants, or departing after a week if she succeeds.

A female treehopper, then, shows a remarkable—though totally instinctual—grasp of her situation. She can make the most of a wide range of circumstances by staying flexible in her behavior. This range of responses insures that she will produce the most young with adequate care and that they will have a good chance of being tended by the best available ant "nannies." □

THE ARMCHAIR SHOPPER

1. The official gazette of our imaginary republic contains not only information on our functional, natural-fabric, travel and safari clothing but also travel tales and trivia, clothing reviews by distinguished critics, unique and soulful artwork. Our offerings include: bush jackets, safari bags, multi-pocketed vests, khaki trousers and shorts, bush dresses. $1

Legacy of Ancient Indians

by Nancy Oestreich Lurie

Anthropologists use the term Woodland in more than one sense. Such is the case with *Ancient Art of the American Woodland Indians*, the catalog for an exhibit produced by the Detroit Institute of Arts. The title refers to a geographic area bounded roughly by the Atlantic Ocean on the east, the Saint Lawrence-Great Lakes waterway on the north, the Mississippi River on the west, and the Gulf of Mexico on the south.

Ethnologists, who work with living peoples, developed the term to classify the broadly similar cultures adapted to the Woodland region at the time of and since European contact, in contrast to the Plains, Northwest Coast, or other geographic culture areas. Archeologists use Woodland in a limited, temporal sense as a period of distinctive cultural characteristics occurring between, and to some extent overlapping, the Archaic (ca. 8000–1000 B.C.) and Mississipian (ca. A.D. 100–1600) periods. The artifacts depicted and discussed in this book come from the Woodland geographic region and were specially selected for their outstanding workmanship and beauty. They include ritual, ornamental, and utilitarian objects of clay, stone, mica, copper, shell, and wood from the Archaic, Woodland, and Mississippian periods.

The exhibit opened at the National Gallery of Art in Washington, D.C., this past spring, is appearing at the Detroit Institute of Arts this fall, and will end its run at Houston's Museum of Fine Arts in the winter of 1985–86. Long after the exhibit is dismantled, this catalog will serve as a valuable reference, as well as a visual delight. Thanks to the magnificent photographs by Dirk Bakker (including fifty-

Saint Louis Science Center

two full-color plates), one can almost feel the shape and texture of the artifacts. Maps further enrich the presentation, as do reproductions of drawings made by Europeans at the time of contact and photographs showing the sweep and grandeur of ancient earthworks as they appear today.

The objective of both the exhibit and the catalog is to promote recognition and appreciation of the prehistoric art of the North American Woodland area. Given the powerful testament of these compelling objects and artifacts, the question arises, why have the artistic traditions of this region been so long overlooked? A partial answer, supplied in the preface by Michael Kan, is that it was not until the 1930s that American Indian objects in general began to be appreciated for their artistic appeal. Kan's discussion of exhibits of Indian art over the past fifty years concentrates on ethnographic rather than archeological materials, but even the more recent appreciation of the artistic worth of archeological specimens has emphasized the Southwest, particularly prehistoric pottery.

In my opinion, historians and the art-oriented public have neglected prehistoric art in eastern North America mainly because archeological work in this area has long been concerned with cultural and historical reconstruction in general. For the nonarcheologist, these studies are pretty dull going. Myriad potsherds and projectile points must be submitted to intensive quantitative analysis for evidence of migrations, relationships, and trade. Painstaking excavation and plotting on paper of changes in earth strata and evidence of post holes, hearths, and middens must be carried out to learn about the size and nature of settlements, dwellings, and domestic arrangements. The mundane facts of everyday life in the successions of ancient sociocultural systems necessarily dominate the archeological literature. Those objects on which exquisite effort was lavished, and which can properly be designated as art, can only be fully understood against this background. For those who want to learn about the people and the circumstances that produced these artifacts, this volume is an excellent introduction.

After an introductory overview, David Penney discusses the Late Archaic period (ca. 3000–1000 B.C.), with a glance back at the beginnings of human habitation in the area, known as the Paleo-Indian period (12,000–8000 B.C.), and the Early and Middle Archaic periods. The latter were characterized by small roving bands using a wide variety of foods—big game, smaller animals, waterfowl, and many edible wild plants—whereas the Late Archaic shows the development of relatively large settlements along river valleys and more specialized exploitation of local ecological conditions. There is evidence of intergroup hostilities but also of extensive trade over long distances. During the Late Archaic, rattles, flutes, and smoking pipes make their first known appearance in this part of North America. The chapter is illustrated with characteristic ground-stone implements and copper artifacts of pleasing symmetry and remarkable beauty. Less familiar Archaic items included in the exhibit are exquisite effigy beads of red jasper in the form of owls and a locust.

The Woodland period is detailed by David S. Brose, curator of archeology at the Cleveland Museum of Natural History. At one time archeologists thought that a sharp distinction could be made between the end of the Archaic and beginning of the Woodland period, but there seems to have been a fairly easy transition from egalitarian bands of hunters and gatherers to more settled peoples with more complex social organization. By about A.D. 500 the Woodland period took on distinctive characteristics. The presence of pottery is the definitive marker of this period, increasing in importance and proliferating into a variety of localized styles as the period wore on. Agriculture also first appears in the region during this time. It is still unclear when plant domestication began, but it may have started in later Woodland times with native plants giving way to maize cultivation introduced from farther south.

Early, Middle, and Late Woodland cultures in their various localized manifestations are discussed and illustrated in terms of effigy pipes, cutouts of birds and other natural forms in mica and sheet copper;

designs incised on stone tablets; pottery; and a wealth of other entrancing objects. Brose deals with the appearance of elaborate funerary customs and the building of round, linear, and effigy mounds in the Woodland period. The relatively familiar Hopewell Culture art is well illustrated, but artifacts from other Middle Woodland cultures show that outstanding artistry was not confined to Hopewell.

The Mississippian period, described by James A. Brown, professor of anthropology at Northwestern University, was clearly based on the trilogy of corn, beans, and squash, allowing the development of large, permanent settlements and cultural elaborations. Brown approaches the Mississippian period in terms of distinctive characteristics and their distribution: platform mounds to support structures, style regions in the Southeast, ancestor cults, the iconography of chiefs, serpent and fertility cults, and the design motifs of the serpent and the skull. Brown's chapter returns to the basic theme, the neglect of the region's prehistoric art. For a long time scholars tended to dismiss Mississippian art as a kind of derivative, poor relation of the art of Mexico. The materials assembled for the exhibit demonstrate that the Mississippian peoples had a vigorous, i digenous art tradition worthy of study an appreciation on its own merits.

As in the other chapters, the illustra tions speak volumes: incised shells wit complex motifs; the recurrent representa tions of the falcon man, the human hand and serpents; decorative effigies on pipe and bowls or free-standing figurines in th form of people, animals, and birds, bot real and mythic; and painted polychrom and incised pottery vessels. Since the cu tures of the Mississippian period per sisted—in some form, at least—lon enough into the early phase of Europea

Hand-shaped mica cutout, Hopewell culture, Middle Woodland period, 200 B.C.–A.D. 400

Ohio Historical Society, Columbus, Ohio

ntact to be noted in the written record, it possible to draw some confident conclu-ons about the function and meanings of any of the Mississippian pieces in the ex-bit. For example, observations by six-enth-century Spanish chroniclers help identify prehistoric stone figurines as presentations of founders of ancestral lts.

The final chapter by Penney, "Continu-es of Imagery and Symbolism in the Art the Woodlands," picks up the story om the Late Archaic to the present. An t historian, Penney discusses the appar-t function of many artworks as "primi-tive valuables," produced to establish and symbolize trading contracts rather than for practical physical use. Some objects appear to have functioned primarily as mortuary offerings.

Although at this time we have no absolute evidence of direct ties between historically known tribes and particular archeological findings, there is no question that the eastern tribes the Europeans met were the descendants, both physically and culturally, of the peoples known to us only archeologically. Drawing upon ethnology and motifs depicted on ethnographic specimens, Penney concludes:

It is fair to assume that Native North American religious practices and beliefs underwent a great deal of change during some three thousand years of history. However, the raw materials of religious thought, the basic world view—or at least the system of visual metaphors used to describe the cosmos—remained surprisingly consistent over the same period of time.

Nancy Oestreich Lurie is curator and head of the Anthropology Section, Milwaukee Public Museum. She is a cultural anthropologist with a special interest in North American Indians, ethnohistory, and museum studies.

Announcing a first-time ever collecting opportunity . . .

Solid 14kt Gold Miniatures of the World's Great Gold Coins

The fifty most significant gold coins from all over the world — as chosen by leading numismatic experts — authentically re-created in finely detailed solid gold miniatures.

Edition limited to 25,000 sets world-wide.
Issue price: Just $35 for each solid gold miniature.

"As rich as Croesus" . . . "the Midas touch" . . . After more than 2500 years, we still speak of Croesus and Midas—rulers of the ancient realm of Lydia in Asia Minor, a land whose rivers were rich in gold, and where the world's first gold coins were issued. And through all the centuries since, gold coins have been the most precious and universally recognized form of money.

Now, for the first time, you will be able to acquire a collection that embodies all the romance, beauty and historical interest of gold coins throughout the ages. A collection of fifty miniatures minted in solid 14 karat gold, re-creating — in authentic and unparalleled detail — the great gold coins of the world.

A remarkable achievement— an exciting collection to own

Creating this important collection has been a long and challenging task. Indeed, more than two years have been spent in *locating* all the original coins and arranging to have them represented in this collection. Thus, it will include authentic replicas in miniature of fifty of the greatest gold coins the world has known—from the *Stater of King Croesus* to the *Brasher Doubloon* . . . from the Persian *Daric* of Darius the Great to the *scudo d'oro* of Florence under the Medici . . . from the 200 *Mohurs* of Shah Jahan—the largest gold coin ever issued—to the high relief U.S. $20 Gold Piece created by the great American sculptor Augustus St. Gaudens—widely regarded by numismatic experts as the most beautiful gold coin of modern times.

Miniature coin (at bottom right) reproduced 4 times larger than actual size to show fine detail.

To re-create these great gold coins of the world in miniature was an enormous challenge for The Franklin Mint's artists, die-makers and engravers. For it was necessary that each miniature gold coin be totally faithful to the original. As can be imagined, achieving the required fineness of detail in such a restricted space requires craftsmanship of the utmost skill and dedication. To preserve accuracy and authenticity, moreover, the miniatures will be *in proportion* to the originals. Thus, the collection will include a variety of both *shapes* and *sizes*.

Presentation case, collector's tongs and magnifier included

So that you can display these miniature gold coins to best advantage, a special presentation case will be provided to house your collection. And to enable you to study each miniature in all its fine detail, a special magnifier and a pair of collector's tongs will be included. In addition, each miniature gold coin in the series will be accompanied by a fascinating commentary written especially for this collection by a noted numismatic expert.

As a subscriber, you will build your collection at the convenient rate of one gold miniature coin per month. And the issue price of $35 will be *guaranteed* to you for each of the solid 14 karat gold miniatures in the collection. To make this important

Housed in a deluxe presentation case with magnifier and collector's tongs.

guarantee possible, The Franklin Mint will commit *in advance* for enough gold bullion to issue the complete collection of gold coins for each subscriber.

This collection of solid 14 karat gold miniatures is available only by direct subscription . . . only from The Franklin Mint . . . and only in this single edition. The total edition is permanently limited to just 25,000 complete sets—a rather small number for a numismatic issue. When each subscriber has received all his miniature gold pieces, the minting dies will be *destroyed*—thereby assuring the rarity of the collection.

An exciting and educational adventure in collecting

There could hardly be a more interesting and worthwhile adventure in collecting than to acquire authentic miniatures of the great gold coins of the world. It is an adventure that will provide endless hours of enjoyment for you and your family. And your complete collection will be a significant legacy for future generations to enjoy in turn.

But, remember: subscriptions will be accepted in strict sequence of receipt and once the numbered limit of 25,000 has been reached, the edition will be closed forever. It is therefore important that you return the accompanying subscription application promptly—and, in any event, by September 30, 1985.

© 1985 FM

SUBSCRIPTION APPLICATION

Solid 14kt Gold Miniatures of the World's Great Gold Coins

A limited edition of 25,000 complete sets.

Nelder Grove, California

by Robert H. Mohlenbrock

When the naturalist and philosopher John Muir was locating and inventorying the stands of California's giant sequoias during the early 1870s, he came upon a handsome grove a few miles south of the now famous Mariposa Grove of Yosemite National Park. As he wandered through the pristine forest, which was bisected by a placid, picturesque creek, he was startled to come upon a small, well-constructed log cabin. In front of it, perched on a bark stool, was an old and heavily weathered pioneer. Several years later, Muir recalled his encounter with this former, mostly unsuccessful gold prospector:

> The name of my hermit friend is John A. Nelder, a fine, kind man, who in going into the wood has at last gone home; for he loves nature truly, and realizes that these last shadowy days with scarce a glint of gold in them are the best of all. He bade me welcome, made me bring my mule down to his door and camp with him, promising to show me his pet trees.

Today, this sequoia grove and the creek that runs through it bear Nelder's name; they are part of Sierra National Forest.

Giant sequoias, whose diameter may reach thirty feet and whose height approaches three hundred feet, are the largest living things in the world. The redwoods of coastal California and southern Oregon are taller, but they lack the great girth of the sequoias. Both trees belong to the family Taxodiaceae, which also includes the swamp-inhabiting bald cypress of the southeastern United States. Giant sequoias have thicker, redder bark and more sharply pointed leaves than the redwoods. Another difference is that redwoods are able to sprout from their stumps, while sequoias cannot.

The sequoias' gigantic size can be attributed to their longevity and the ample supply of moisture and nutrients where they live. Unlike animals, most plants continue to grow throughout their lifetime. If moisture and nutrients are plentiful, they may grow rapidly. Sequoias survive fires because their soft, spongy bark is up to two feet thick. The wood itself is decay resistant, making the trees less susceptible to damage by insects and fungi (even fallen sequoia logs may remain intact for hundreds of years before beginning to show signs of deterioration). Thus the trees can live to ripe old ages, growing taller and thicker each year. The General Sherman Tree in Sequoia National Park, apparently in its prime of life, is probably nearly 3,000 years old and still going strong. Speculation that some sequoias alive today may live to be 10,000 years old provokes heated debate among biologists.

A sequoia usually doesn't begin to for cones until it is at least 125 years old. C average, a mature tree produces son 1,500 cones per year. Each cone tak about eighteen months for its 150 to 3 seeds to mature, and the seeds may not shed for as long as twenty years. The livi part of the seed is only about one-quart inch long, yet it has the potential of de- oping into a tree that may contain 50,0 cubic feet of vegetable matter. Approx mately two-thirds of the seeds are abno mal, and one-fourth of the rest are likely be damaged by the Douglas chickaree reddish squirrel) and other animals. Th seeds that do germinate successfully r main in a precarious position, since desi cation of the soil during a seedling's fir few years will probably cause it to die.

The sequoia seed germinates with th formation of a tiny taproot, sometim

---

while snow still covers the ground. After a few years, the taproot is replaced by an extensive network of feeder roots that eventually may extend outward as much as 300 feet and cover three acres. The bark remains gray until the tree is about twenty years old; then it takes on its characteristic fibrous texture and rich red color.

For the first 150 to 300 years of its life, the giant sequoia is shaped like a Christmas tree, tapering to a graceful, pointed top, but as the years progress, the branching pattern results in a broadly rounded top. Because of its great height, the giant sequoia is vulnerable to lightning strikes, which may knock out part of the crown. Many old trees also exhibit "snag-tops," which are dead branches in the crown. They result when ground fires damage part of the water-transport system within the trunk, cutting off the supply of water to the affected branches high up the tree.

Nelder Grove is one of seventy-five distinct stands of giant sequoias that dot the western slopes of the Sierra Nevada for nearly 250 miles, from about twenty miles west of Lake Tahoe south to within forty miles northeast of Bakersfield. My first hike through Nelder Grove's tranquil Shadow of the Giants Trail came less than an hour after I had been jostled in a crowd of tourists as we were bused in and out of the Mariposa Grove in Yosemite. Mariposa Grove is parklike, with trees that have never felt the woodsman's ax and an understory kept clean through the removal of brush and the trampling by thousands of visitors each year. Beneath the tall trees in Nelder Grove, in contrast, is a dense growth of small trees, shrubs, and wildflowers that would be difficult to traverse were it not for the hiking trail.

Within two decades after John Muir had chanced upon his hermit friend, about half of the giant sequoias in the grove were cut off as much as twenty feet above the ground, and the great tops of the trees crashed to the forest floor, often splintering into uselessness. Giant limbs and huge stumps were left in the forest by the lumbermen who destroyed one-third of the giant sequoias in the nation between 1880 and 1930. Fewer than fifty mature sequoias were spared in Nelder Grove.

The trees that fell, either through natural causes or people's destructive for and the dense, brushlike vegetation ensued, provided fuel for fires, which u der natural conditions rage through quoia groves as often as five times ea century. Trees that grow with the quoias, such as white firs, sugar pines, a incense cedars, are able to survive only few of these fires, but sequoias, with th thick, asbestoslike bark, show only bu scars after a fire and are seemingly only little the worse for wear. A sequoia mo than 2,000 years old may have felt t heat of one hundred fires in its lifetim but it continues to grow and reproduce

As long as sequoias, firs, pines, and c dars—all capable of growing taller th 200 feet—live unmolested in a grove, th create a thick canopy that little sunlig can penetrate. In addition, their masses fallen leaves accumulate on the fore floor. Under these conditions of den shade and heavy ground litter, sequo seeds will not germinate. This is true Mariposa Grove, where lumbering h never occurred and where fire has be suppressed since the establishment of Y semite National Park. Ironically, the e fort to protect such mature stands of s quoias has threatened their regeneratio

But where sunlight pours in and the so is scarified by fire or human disturbanc sequoia seeds may germinate and develo into saplings. Nelder Grove is such place. There hikers can see trees that a less than 100 years old, a new generatio of future giants.

"This Land" highlights the biologic phenomena of the 153 U.S. national fo ests. Robert H. Mohlenbrock is disti guished professor of botany at Southe Illinois University at Carbondale.

Nelder Creek, above. The 2,700-year-old Bull Buck tree, right.

To the Spirit of the Oo

by Marc Breslav

Just beyond the rim of Maui's highest crater, Stephen Mountainspring rediscovered the Bishop's oo in a Hawaiian rain forest. The species, *Moho bishopi*, was last sighted in 1904 and had been presumed extinct by most authorities until 1981, when Mountainspring spotted it on the windward slope of the immense Haleakala crater. It had also never been seen with assurance on Maui and was known historically as a bird of Molokai. However, the two islands were joined until the end of the last glacial cycle, some 10,000 years ago.

The Bishop's oo (pronounced ōō) is a member of the honeycreeper family (Meliphagidae), which numbers 170 species hailing from Australia and the South Pacific islands. Four species of oo have been known to science, each limited in range to a different Hawaiian island. Three of these, from Oahu, Molokai, and Hawaii, have not been reported since the beginning of this century and have thus been considered extinct. The Kauai oo had also been thought extinct but was rediscovered in 1960. Ornithologists now believe that fewer than ten individuals of this species remain. Prior to Mountainspring's discovery, no oo was known from Maui, although there had been scattered reports over the last century of oo-like birds of undetermined species. His sighting was therefore doubly significant: it not only resurrected one of the Hawaiian Islands' presumedly extinct species but also confirmed its previously hypothetical occurrence on Maui.

According to Mountainspring, "the fossil record and other historical evidence indicates that 70 percent of Hawaii's native land birds became extinct prior to the arrival of Western settlers." The causes of the Bishop oo's decline, however, are more related to nineteenth-century postsettlement influences. For example, in 1826, vengeful sailors dumped water infested with mosquito larvae into a water system, reportedly because the ruling chiefs denied them access to Hawaiian women. The nonnative mosquitoes became carriers of avian malaria and pox, with drastic results for native birds that had no resistance to these foreign diseases. Likewise, introduced predators, such as rats and cats, attacked birds unaccustomed to such mammals. Finally, indiscriminate grazing by cattle caused significant habitat destruction. Allowed to roam freely in the jungles, cattle fed on plants that did not have the thorns or other defenses present among continental flora.

But in the remote, high elevation of Haleakala, the oo may have found some sanctuary from human influences. Its very distance from habitation and its altitude had made Haleakala a special place, even to ancient Hawaiians. According to one Hawaiian myth, Haleakala,"the house of the sun," is the place where the ancient god Maui lassoed the sun by its "legs," or rays. The sun, fond of sleeping, had been racing across the sky to retire early for the night. But the short days that resulted left too little time for the Hawaiians' bark cloth to dry. One morning Maui caught the sun by its legs, just as it rose over the crater's rim. In return for its freedom, the sun agreed to walk more slowly across the sky.

Like the other Hawaiian Islands, Maui absorbs the sun's heat, creating an inversion layer of warm air at seven to nine thousand feet. Trade winds, heavy with moisture picked up while crossing a thousand miles of open ocean, rise as they cross Maui until they reach this inversion layer. Cooling as it gains altitude, the moistur condenses as rain. Haleakala is hig enough that little of the moisture passe over its 8,500-foot windward crest. Thus the brunt of the area's rainfall—some 25 inches per year—drenches Haleakala' windward slope at elevations between fiv and seven thousand feet, supporting a ver dant rain forest. On the lee side of this rim lies the dry expanse of the crater floor.

Mountainspring was working, as he stil does, for the U.S. Fish and Wildlife Ser vice on Hawaii when he began the excur sion that was to lead to the oo's discovery He flew to Maui early in May 1981, then hitchhiked to the leeward rim of Halea kala, which at 10,026 feet is the highes point on Maui. Here the road ended, and Mountainspring descended by foot into the crater, whose moonscape floor lay 3,000 feet below. It was on this same pow dery desert floor that the Apollo astro nauts trained for their missions.

Carrying a fifty-pound backpack Mountainspring began an eight-mile trek across Haleakala's cinder bottom, a dusty expanse crisscrossed by rugged lava flows. A line of red and black cinder cones roughly paralleled the route. At dusk, he set up camp to the sound of petrels calling as they returned to their nesting burrows.

The next morning, he wound his way through patches of Haleakala silversword, a rare plant endemic to the alpine deserts of Hawaii, and climbed up the 1,600- foot backside of the crater. Leaving the ridge trail behind, he dropped down the windward slope through an alpine grassland, stopping just at the upper limit of the rain forest to set up base camp.

From his camp, Mountainspring made daily trips into the rain forest. His remote study site had been unexplored by or-

American Museum of Natural History Visitors' Information

Admission. Admission is on a pay-what-you-wish basis, but visitors must pay something. Admission is free for Museum Members.

Admission to the Hayden Planetarium is separate from the Museum. For Planetarium information call (212) 873-1328.

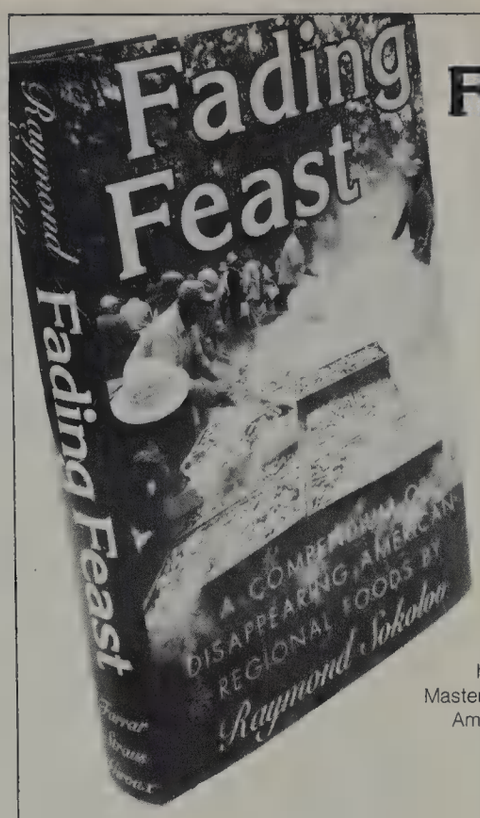
IMAX Theater. New York City's largest movie screen — over four stories high — is in the Museum's IMAX Theater. For prices and showtimes stop by the box office, located at the 77th Street entrance, or call (212) 496-0900.

Special Events and Programs. Pick up a free copy of *Rotunda* when you enter the Museum to find out about special events. You may also want to visit: the Alexander M. White Natural Science Center, which introduces people to the natural science of New York City; the Frederick H. Leonhardt People Center, which presents music, dance, and lecture-demonstrations of world cultures (weekends only); and the Discovery Room, which has hands-on activities for children. For a free guided tour, stop by any information desk and ask about the Museum Highlights Tour.

Official Guide to the Museum. To make the most of your visit, purchase the Museum's guidebook. It tells the story of Museum exhibits and provides background material about the dinosaurs, minerals and gems, mammals, birds, anthropology, meteorites, and much, much more.

Membership. Membership in the Museum offers many exciting privileges and benefits, including a subscription to *Natural History*, free admission, special events, and discounts in the Museum Shop and Members' Book Program. Write for free brochure.

For More Information. Write to: American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024.



FADING FEAST

A Compendium of Disappearing American Regional Foods

by Raymond Sokolov

"If you care about American cooking, as I do, you will find *Fading Feast* an enormously rewarding book."
—Craig Claiborne

The culinary wisdom of our American past in over 100 recipes and their stories.

$17.95 ($14.36 for Members) plus $1.50 shipping and handling per order. To order: call toll-free, (800) 247-5470; MasterCard and VISA accepted. Or, mail check, payable to the American Museum of Natural History, to the address below.

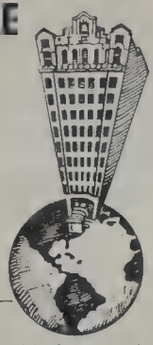
THERE IS NO OTHER STORE IN THE WORLD LIKE HAMMACHER SCHLEMMER. AND NO OTHER CATALOG.



It has been said, "If you can't find it anywhere else look for it at Hammacher Schlemmer—especially if it's new."

For well over a century New Yorkers and ex-New Yorkers around the world have looked to Hammacher Schlemmer for things ahead of their time—the first portable radio, the first automatic coffee maker, the first microwave oven—and hundreds of other products before anyone else had them.

In our new catalog you'll find the Only Electric Zoom Miniature Binocular, the Infrared Home Intruder Alarm and still hundreds more of unusual things that can't be found anywhere else. Come to the famous store on 57th Street or send for the current catalog while it's still available.

Hammacher Schlemmer, Dept. 944

nithologists until the late 1940s. It was this dense forest that the poo-uli, a hon creeper that feeds on mollusks, was fou in 1973. Here, too, this century's fi sighting of the Maui parrotbill was ma in 1950, followed in 1967 by the redisc ery of the Maui nukupuu, a honeycreep whose upper bill is twice as long as lower. These discoveries had given t area and its birds a certain elusive spark Spending days in this misty rain fore Mountainspring sighted many of the birds and others with exotic Hawaii names. The red pompon flowers of t dominant ohia tree (*Metrosideros*) co trasted brilliantly with the tree's twist dark gray branches and drab green liage. Thick moss and fern epiphyt jacketed the branches. Sheer gulches, c ated by eons of heavy rains, cut throu the luxuriant understory of small tr ferns and shrubs.

On May 10 at 10:00 A.M., Mou tainspring heard a series of long, accent "owh-owh" notes of low pitch and so rich tonal quality. From his readin about rare Hawaiian birds, he suspect that he had heard a supposedly extin species of oo. If this was an oo, he kne that it was reputed to be extremely shy. Mountainspring later recalled, "It w like a field test of all my years of exper ence to stalk the bird and find it."

He crept toward the songs through th dense understory and came to an overlo above a sheer gulch. He waited there f three hours, surveying the forest along th opposite gulch wall. Suddenly, a lon tailed black bird flew from the understo into the subcanopy. "I felt like a myste of the primeval Hawaiian forest was bein unveiled to me," Mountainspring said.

The moment he saw the bird, he starte to run through the identification proces honed by years of field experience. He be gan by looking at the bird's color an shape, immediately burning its essentia image into his mind so that he could rel cate it if it moved or have a minimal men tal record if it vanished in the dense vege tation. He recorded several field marks— the black tail, the yellow ear patch, and yellow tuft under the wing. He the looked for other specific field marks an behaviors. The process complete, he scrib bled notes and made sketches, recordin his observations in accordance with th stringent requirements of his profession

Only then did Mountainspring realiz that he was indeed seeing Bishop's oo, a species that had purportedly long since vanished into oblivion. Overcome by wha he later described as "a wave of bliss," Mountainspring was now able to drink up the scene more metaphorically.

Walter Rothschild's turn-of-the-century painting of the Bishop's oo

He felt, suddenly, a strong sense of ce, a sense, as he described it, "of really ng there . . . I fell into the scene before , retaining remarkably sharp and clear pressions of the vegetation and sky pat- n." For him, a curtain had been parted, ealing the image that Longfellow so y recorded in the first line of *Evange- e*: "This is the forest primeval."

Mountainspring broke camp a few days er to return to civilization. When he re- ned the trail that had led him to his iso- ed study site ten days earlier, his weath- d tracks were still the only ones printed in the mud.

It was perhaps fitting that Moun- nspring's trip was financed by an Amer- n Museum of Natural History grant m the Frank M. Chapman Memorial nd. As Mountainspring was bringing ck ornithological headlines from the aui rain forest, so, too, had Chapman ought back to the Museum many dis- veries from his fieldwork in the simi- ly remote jungles of South America.

On his return, Mountainspring examined specimens of the oo, studied historical records, and then published his report in *Elepaio*, the major ornithological journal of Hawaii. This, along with a letter to the chairman of the American Ornithologists' Union (AOU) Committee on Classification and Nomenclature, caused the committee to remove the mark indicating an extinct species from beside the Bishops oo entry in the *AOU Check-list*. The official arbiters of such matters had accepted Mountainspring's record, thereby resurrecting Bishop's oo.

Perhaps not coincidentally, at the age of eight, Mountainspring acquired his first bird book, an original, leather-bound edition of Chapman's *Handbook of Birds of Eastern North America*. It cost him fifty cents at a rummage sale and sparked his lifelong interest in ornithology.

Don't Buy a BIG TILLER...

For a Small Job!

Buy a Mantis!

Big tillers weigh almost 300 lbs. Mantis weighs just 20 lbs. (women and older gardeners love it)!

Simply turning a 300 lb. tiller in a backyard garden is a challenge. Mantis starts with a flick of the wrist . . . turns on a dime . . . and weeds between narrow rows and along fence lines.

The Mantis takes the work out of growing flowers and vegetables . . . so you can have more time to enjoy the results!

Most big tillers were designed to just till, Mantis was designed *from the beginning* for a variety of useful attachments. Tiller. Weeder. Furrower. Edger. Lawn Aerator. Lawn De-Thatcher. Hedge Trimmer.

Best of all, Mantis costs a *fraction* of what you'll pay for a big tiller.

3-Week In-Your-Garden Trial!

Mantis has a *Lifetime Warranty* on the tines (if they ever break, we'll replace them). A *Lifetime Replacement* agreement on the engine. And a *3-Week In-Your-Garden Trial* (if you don't like it, we'll take it back and give you a full refund).

"The Mantis is compact, yet it still accomplishes big garden jobs! We've used it to till up a flower bed, prepare a strawberry patch and dig trenches for planting asparagus. We even used the Mantis to cut sod pieces for our lawn."

Workshops for Young People

The Museum's Education Department is offering its *Workshops for Young People* again this fall, with such programs as: *Through the Eyes of a Child*, which introduces the Museum to five- and six-year-olds (accompanied by an adult); *Nature Activities for the Very Young*, for children in first and second grade; *Learning to Draw Animals*, for grades six, seven, and eight; *Origami*, for grades five and six; and *Discovering the Microscopic World*, an introduction to the microscope for children in grades six and seven. Fees for the workshops range from $10 to $30 (10 percent discount for members), and most begin in October and November. For more information, call (212) 873-7507.

Art of the Cameroon

In September and October the Education Department will offer a series of lectures to complement *Art of the Cameroon*, an ongoing exhibition. On September 22, Tamara Northern will deliver a slide lecture, "The Royal Art of the Cameroon Grassfields," in the Museum's Kaufmann Theater. Sylvia Boone will present "Masterpieces of Cameroon Art" on Sunday, October 6, in the Kaufmann Theater. Both take place at 2:00 P.M. and are free and open to the public.

Tiger, Tiger, Burning Bright

A photographic exhibition opens in Naturemax Gallery on October 1. *Tiger, Tiger, Burning Bright—An Indian Wildlife Portfolio* includes spectacular pictures of such Indian animals as the tiger, elephant, and thamin deer.

Faces Film Festival

Children ages six to fourteen are invited to a film festival sponsored by *Faces*, the Museum's new magazine, and the Membership Department. Three short anthropological films will show how children around the world live, work, and play. Among the subjects will be Eskimo children playing indoor games, the daughter of Polish immigrants in Canada, and a Navajo girl as she herds her sheep alone for the first time. A craft activity will also be included. Free copies of *Faces: The Magazine About People*, geared to eight- and fourteen-year-olds, will be given away to participants. *Faces* is published by Cobblestone Publishing in cooperation with the Museum. This free program for Museum members only will take place on

Peter Getzels, Harriet Gordon

Oriental Passag

April 4 to May 7, 198

Relax on the Museum's exclusively chartered cruise vessel, *Illiria*. This small gem of a ship offers pampered service, superb food, and luxurious surroundings. Each excursion on land is designed to provide a rich and diversified experience of the history, art and culture of the ancient world. And the trip offers leisure to enjoy swimming, strolling, shopping or simply relaxing.

Halley's Comet, together with a lecture team, itinerary and cruise vessel that cannot be duplicated...call or write the Museum's Discovery Tours office for detailed information.

A scene from In the Footsteps of Taytacha

Sunday, September 29, at 11:00 A.M. and 1:00 and 3:00 P.M. For more information call (212) 873-1327.

The 1985 Margaret Mead Film Festival

The 1985 Margaret Mead Film Festival will feature forty-five films this year, twenty-six of which will be shown for the first time in New York. Covering a spectrum of anthropological subjects, the festival includes a documentary of daily life in a Chinese village and a Werner Herzog film on a mountain climber. Other highlights are:

A Man When He Is a Man, a humorous portrayal of male posturing in Costa Rica, also raises serious questions about male attitudes toward women.

The Memory of the Camps, a devastating documentary of German concentration camps during World War II, filmed during the Allied liberation.

Panare records the life of Amazon peoples as they strive to maintain their identity in a changing world.

Films will be screened Monday through Thurday, September 9–12, from 6:30 to 10:30 P.M. Tickets, available at the door each evening, cost $3.00 for members and $4.00 for nonmembers. For information and a complete schedule of the films call the Education Department at (212) 873-1070 on weekdays.

WILD AMERICA IS OUR CAMPUS

Career programs leading to AA, B.S. and M.S. degrees

You can't fully learn about the environment by sitting in a classroom. Our expeditions are small groups of inquiring college, high school, graduate students and faculty who travel across America as a learning community. As we camp out September-May or summers—hiking, canoeing and skiing—we visit people and places to encounter deep ecological problems, society and self. Our 4-week to 4-year cross-cultural studies —Newfoundland to California—lead to naturalist, outdoor and educational livelihoods.

The Expedition Education Advantage. ❑ incorporates all previous undergraduate coursework, ❑ offers accredited career internships, independent study, life experience credit and transferable coursework, ❑ awards financial aid and career startup funding.

Send for complete information packet or inquire:

National Audubon Society
Expedition Institute
Dept. H; Sharon · Conn. 06069
(203) 364-0522

Students are admitted regardless of their race, sex, religion or national origin.

The Earth's Crust Also Rises

An unmanned spacecraft has measured the upward motion of large porti of the earth, a consequence of the ending of the last Ice Age

by Stephen P. Maran

When last discussed in these pages, a NASA satellite named Lageos was slowly but seemingly inexorably losing altitude (see "Fall from Space," *Natural History,* December 1982). From that unexpected circumstance, it was deduced that a weak electrical force was tugging at Lageos, making it descend. The slow fall could bring the 905-pound craft crashing down on the earth 500,000 years from now, instead of in the millions of years originally expected. However, since our previous report, the rate of descent has varied and the satellite may even be rising at times. Of still greater interest to geophysicists is another, more subtle change in the satellite's orbit. This effect, called nodal acceleration, seems to be due in part to slow changes in the earth's gravity, which are caused by the upward motion of the land in Canada, Finland, Scandinavia, and other regions that were covered by huge ice sheets during the last Ice Age.

If I could carry a tune, I would be humming Rodgers and Hammerstein's "My Favorite Things" at this point in the story. That's because Lageos—short for Laser Geodynamic Satellite—is my favorite spacecraft. Unlike nearly all other satellites and probes, it does not require hundreds or thousands of radio-transmitted commands every week to keep it functioning. In fact, it is no bother at all. No command that NASA controllers can issue would have any effect on Lageos's faithful completion of its appointed rounds; the satellite has no onboard radio receiver to accept commands and no computer or other equipment to execute them. Unlike such manned spacecraft as the space shuttle, Lageos follows no mission rules but operates instead under the laws of nature. The challenge it presents to the scientist is to infer the finest details of some of the laws from the changes in Lageos's or that occur over time.

To determine the changes in Lageo orbit, the craft is tracked from the grou by laser. The lasers can home in on the s ellite because its two-foot-diameter out skin is studded with 426 retroreflecto optical devices that have no moving pa but that flip incoming light beams direct back at their senders. Thanks to the desi of the satellite, the careful choice of the bit in which it was initially placed, and t laser tracking, Lageos's present, slow changing orbit has been determined wi higher precision than that of any previo satellite. Therefore, as Lageos orbits t earth, it functions as a roving referen point, so that measurements of its pa over tracking stations at various locatio can be used not only to find changes in t satellite's motion but also to ascerta changes in the positions of the statio themselves. Laser tracking stations are s up on different continents, thereby e abling investigators to follow the con nents as they drift with respect to one a other at almost unimaginably slow rate Tracking stations are also located on bo sides of the San Andreas fault zone California, making it possible to monit the slippage of the land along the zone.

Among the geophysical phenomena r vealed in precise detail through the trac ing of Lageos was a tiny, measurable, ten porary increase in the length of the da apparently related to an especially stron occurrence of the Pacific Ocean's El Ni disturbance in 1982–83. This discover was confirmed by independent measur ments made with radio telescopes tha used quasars as fixed reference points fo determining the earth's rate of rotatio

ner findings from the laser tracking a include measurements of slight anges of a few inches in the positions of north and south poles of rotation, ich are several yards from the geo-aphic poles.

Scientists initially assumed that La-os's orbit was so stable that the craft uld continue revolving around the earth millions of years. Then, should all life destroyed, either by human or natural astrophe, Lageos, surviving high above ground, might constitute important dence of the advanced state of civiliza-n that we had once attained. By captur-; and examining the orbiting satellite, raterrestrial visitors to the solar system uld learn something of the vanished in-bitants of our planet.

To assist in this educational process, geos carries within its protective alumi-m shell an informative plaque with a ssage for potential finders. Designed Carl Sagan of Cornell University, the aque features graphic depictions of the proximate positions of the continents at ee widely separated points in time, in-ading the May 1976 date on which geos was launched into space. By de-ding the data encrypted on the plaque d comparing the disposition of the con-ents at the time of the hypothetical visit th the maps on the plaque, the time apsed since the satellite was launched uld be inferred.

Knowing all of the above, I learned with reboding in 1982 that Lageos was unex-ctedly falling at the rate of 1/25 of an ch per day, ten times faster than antici-ted. Even Lageos, it appeared, is not rmanent. But there was an interesting delight to the bad news. David Rubin-m, a geophysicist colleague of mine at

Audubon's *Birds of America* Complete!

Catalog of the most recent sale of Audubon's peerless BIRDS OF AMERICA, owned by the Earl of Caledon. (Auctioned at Sotheby's, January 1985.) Features illustrations of every print (all 435), including 38 in full color! List of latest auction prices for each print included. An excellent reference for Audubon collectors and anyone interested in this great naturalist.

TO ORDER

A limited number of the Sotheby's BIRDS OF AMERICA catalog have been reserved especially for Museum Members at the special price of $14 each, plus $2 shipping. Please send check to Members' Book Program, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024. To order by phone (VISA or MasterCard accepted) call toll free 800-247-5470.

AFRICA SAFARI

On safari with TRAVCOA you'll observe the rare mountain gorilla, great migrations of the Serengeti Plain, and the wildlife of Botswana and Virunga.

Historical kingdoms, village markets and African customs unfold as we visit Cameroon. Travel on South Africa's luxurious Blue Train, balloon over the Masai Mara and stay at famed Governors' Tented Camp.

SOUTH PACIFIC

TRAVCOA's South Pacific includes the Australs, Western Samoa, and a cruise from New Guinea's Sepik River to the Trobriand Islands where colorful customs of a primitive culture survive today.

Tour Michener's Rurutu, Bora Bora and the Kingdom of Tonga. Travel from Sydney to Perth aboard the Trans-Australian Railway. Visit Tasmania, Fiji, the Maori country of New Zealand and see Fire Walkers in Rabaul.

SOUTH AMERICA

From Incan civilizations to Antarctica, TRAVCOA offers a surprising contrast of cultures, wildlife and exotic cities. Cruise the Amazon and Galapagos, explore Patagonia, and marvel at the giant statues on Easter Island. For an exciting expedition, live at a research station in Antarctica.

TRAVCOA's unusual Mexico offers ancient Mayan cultures of Chiapas and Palenque and the amazing sites of the Yucatan. Enjoy gala evenings and dine in the finest restaurants and cafes.

TRAVCOA tours are limited to 25 persons, with luxury facilities and a la carte dining.

Goddard Space Flight Center, concluded that Lageos's fall was due to the buildup of an electric charge similar to the static electric charge that builds up in your body when you walk across a rug. Once so charged, the satellite is susceptible to an electric force, called plasma drag, that is exerted by electrified gas in its orbital surroundings. That seems to be the cause of Lageos's fall, and that is where we left the reader in December 1982.

Since 1982, Rubincam and others have found that the rate at which Lageos descends is varying. Sometimes the descent rate approaches zero, meaning that the satellite's slow fall almost stops. One study suggested that Lageos had begun to rise. However, it now seems to be falling. These unexpected variations in the satellite's descent may be due to changes in a pressure force exerted on it by sunlight reflected from the earth. Such light is called earth albedo. We have known for more than two decades that earth albedo can disturb the motion of satellites, and these well-understood effects were taken into account before the Lageos investigators concluded that an additional process was affecting the motion of the satellite. What's new is that the gradual changes in Lageos's orbit have been determined with such precision that investigators have detected among them the apparent consequences of variations in the amount of sunlight that is reflected in the Northern and Southern hemispheres.

At least, that's the conclusion to which four Italian physicists at three institutions in Pisa are leaning. According to the Italian scientists, the differences in the earth albedo emanating from the two hemispheres (which, in turn, depend on the season of the year) can account for the unexpected variations in Lageos's rate of fall. Another investigator suggests that additional changes in the earth albedo, which correspond to different times of day, contribute to these variations. This inv gator specifically proposed that syst atic differences in the amount of earth bedo shining on Lageos as the sate moves through dawn and dusk on its o are what change the rate of fall. This cess may even rival plasma drag in br ing the satellite down.

Geophysicists have been studying other phenomenon derived from l tracking of Lageos. Lageos's orbit in sects the plane of the earth's equato two points, called nodes. The position the nodes move, and when the rate nodal motion changes, the phenomeno referred to as nodal acceleration.

Nodal acceleration in the orbit of a ellite can be caused by such forces ocean tides. However, when all previou identified causes were subtracted fr the observed nodal acceleration of geos's orbit in two recent independ studies, a small but certain measu acceleration remained. The studies w prepared by Rubincam and by a team by Charles F. Yoder, an astronomer at Jet Propulsion Laboratory in Pasade California. Although the studies agree the meaning of the nodal accelerat they disagree on its magnitude. Yoder group, which published first, fou an acceleration about twice as great that later calculated by Rubincam. But the investigators agree that the accele tion results from postglacial rebound the slow rise of landmasses in the Ca dian Shield, Scandinavia, Finland, a elsewhere that were depressed by weight of overlying ice sheets during last Ice Age, which ended perhaps as cently as 5,000 years ago.

The observation of postglacial rebou is not a surprise: geologists have kno about it for decades; the Swedish bish of Abo noticed it in 1616; and aborigi

Along the San Andreas fault, land slippage is tracked by lasers. R.N. Mariscal; Bruce Coleman

ups recognized the rise in the land long
Scientists began to understand the
se of this rise after several pioneering
lies in the nineteenth century. One of
e geologic surveys concerned the coast
Maine and was published in 1874 in the
noirs of the Boston Society for Natu-
History. The Maine surveyor, N.S.
ler, approached his coastal study skep-
lly, since he suspected that many pre-
is reports of the rising level of the rocks
originated with sailors and ships' offi-
in need of natural explanations for
wrecks for which they might other-
e be held accountable. Shaler consid-
d that a sailor who ran his ship aground
the coast of Maine "was naturally in-
ed to foster the opinion that the rocks
e growing nearer the surface year by
r." Nevertheless, from his study of an-
nt seashells found far above the con-
porary sea level and other geologic evi-
ce, Shaler confirmed that the sea level
changed in a way consistent with a
in the land, and he made an important
tribution by pointing out that this ef-
is pronounced in regions once covered
glacial ice sheets. Similar work by a
ish contemporary of Shaler showed
same correlation between a rise in the
d and the previous burial of that land
er a glacial ice sheet in the British Isles
elsewhere.

Since Shaler's time, geologists studying
tglacial rebound have determined the
rage rate at which the land has risen
e the last Ice Age. The nodal accelera-
in Lageos's orbit now enables geo-
sicists to measure the current rising of
land, thus confirming that the process
till under way. Furthermore, because
nodal acceleration depends on the re-
ribution of mass within the interior of
earth and not simply on the level of the
d surface, the measured acceleration
vides basic new information on the vis-
ity of the earth's mantle, the layer just
eath the earth's crust. Although the
ntle consists of rock, the great pressure
temperature at depths of many miles
ke it resemble an extremely sluggish
ving fluid.

Geophysicists still hope that one day
p-drilling experiments will penetrate
earth's crust and directly sample the
k of the mantle below. Until then, the
er tracking of Lageos will continue to
vide a sophisticated way to explore our
net's inner as well as outer space.

For the cost of a morning coffee break, you can break the cycle of poverty for one small child.

It may not seem as though 72¢ will go very far these days. But for a small child like this, it can lead her out of desperate poverty and into a future of hope.

And right now, you can reach out and make that future happen... by sponsoring one child overseas through Foster Parents Plan. For only 72¢ a day, you can make it possible for your Foster Child and family to have adequate food and clothing, a decent place to live, needed medical care, education... *and the chance for a better life.* Because while you're helping, the child's own family will be working with Foster Parents Plan to develop the skills and resources they need to help themselves.

You'll be amazed at the difference you can make. And you'll see the difference for yourself. In photographs. Detailed progress reports. And heartwarming letters from your Foster Child. You'll be doing so much for that child... and for so little.

Won't you help now? Simply mail the coupon today or call toll-free. It could be the biggest break a child ever got.

Founded in 1937, Foster Parents Plan will this year aid over 256,000 Foster Children and their families in more than 20 countries. We are non-profit, non-sectarian, non-political. A detailed financial audit is available on request. Your sponsorship is 100% tax-deductible.

To start helping even faster, call toll-free:

Lovely Mornings

Thomas D. Nicholson

Mars recovers quickly from the obscu- of its conjunction with the sun in Au- and climbs rapidly into the morning it can be seen before sunup by mid- nth. Mars joins Venus and the bright Regulus (in Leo) to make an interest- threesome in the dawn sky. Venus is obvious leader in brilliance; Mars is laggard and the easternmost (lowest) ne three. Mercury can also be found in morning twilight, low in the eastern during the early part of September. umn morning configurations of the net are always the best.

The planetary scene is clearly shifting y from the evening sky in September, he morning improves. If not for Jupi- the evening would be rather poor. Ju- r's only competition comes from Sat- , not particularly distinguished in earance, which is to the south of our and sets soon after darkness. Jupiter is ething else again. At about dark it be- to appear near the south and remains he sky until well after midnight. The on may help in finding Saturn on the n; thereafter it will be obscured by the izon haze.

The following events are given in local e unless otherwise noted.

September 1: The moon is already two a half days past full, yet moonrise is about an hour after sunset. It's the rvest moon" effect displaced a bit. onlight lasts virtually from dark until n tonight. When the moon climbs ner, you will find it near the border of ces and Cetus.

September 2–3: Still waning, the moon ves through Pisces into Aries.

September 4: Mercury almost covers rs while passing below it tonight, com- within a half minute of arc, about the of a dime seen at a distance of 400 . Unfortunately, the two planets are up in daylight and are located where we 't see them. The moon is at apogee, far- st from the earth.

September 5: The moon is near the Ple- es when it comes up tonight after 9:00 . The closely gathered stars of this clus- (sometimes called the Seven Sisters) just above the moon and to its right.

September 6–7: The waning moon passes above the Hyades, a V-shaped star cluster in Taurus, the Bull. The bright red star in the V is Aldebaran. Last-quarter moon is at 7:16 A.M. on the 7th.

September 10: The morning moon is in Gemini, nearly in line with and below the constellation's twin stars, Pollux and Castor. Much brighter Venus is below the moon to its left.

September 12: Venus and the old moon are always a pretty sight, and you should see them this morning about dawn. We won't see the moon again until it passes the sun and emerges to its left as an evening crescent.

September 14: New moon, at 2:20 P.M., EST, is moving across the border between Leo and Virgo, along with the sun.

September 16: Now two days past new, the young crescent moon can be glimpsed in Virgo tonight, just above the bright star Spica, if the southwestern sky is clear. Perigee moon, nearest the earth, was earlier today.

September 18: Saturn rides the sky with the crescent moon tonight, although the moon is drifting slowly to the left and beneath it in Libra.

September 19: The moon has left Libra behind, along with Saturn. The lunar companion tonight is Antares, in Scorpius, although the moon is slipping to the left into Ophiuchus.

September 21: Regulus is very near Venus this morning; the planet passes a moon's diameter (0.5°) away at noon. The moon, at first quarter at 6:03 A.M., is in Sagittarius.

September 22: The sun crosses the equator in Virgo today, on the way south of it, at 9:08 P.M., EST, and autumn begins in the Northern Hemisphere. Most years autumn starts on September 23, but the "breaks of the game" we play with leap year cause the time to vary. Autumn begins on the 23d in Asia, Africa, Australia, and Europe, but the changing date doesn't catch up to us until later.

September 23: Jupiter is moving slowly to the west (right) through Capricornus (it's retrograding), while the moon is moving to the left just to the planet's south. The effect is obvious at 1:00 A.M. (on the

Gstaad Down Comforter
& DOWN PILLOWS
MANUFACTURER DIRECT

A year-round down comforter named for the famous Swiss ski resort Gstaad (pronounced städ). The silky smooth fabric is imported European 100% cambric cotton (226 per inch thread count). The exclusive ring stitch design has many more intricately hand-sewn circles than other ring stitch designs (180 rings in a Queen size comforter to be precise). Thus, we achieve a beautiful sculptured effect. The ideal solution for year-round sleeping comfort... nestled under the luxury of the finest European down and the irresistable feel of soft 100% cambric cotton. **Our Guarantee:** If for any reason you are not completely satisfied with your purchase, please return it for a full refund. Delivery: We ship within 24 to 48 hours.

TO ORDER CALL TOLL-FREE 1-800-356-9367, Ext. H615, or use the coupon. Or, call or write for your free catalog featuring 20 down comforter styles, down pillows, designer down coats, 100% Merino Wool products and many other natural products designed to improve the quality of your life.

24th), as the moon drifts toward Jupiter, past it, and then away.

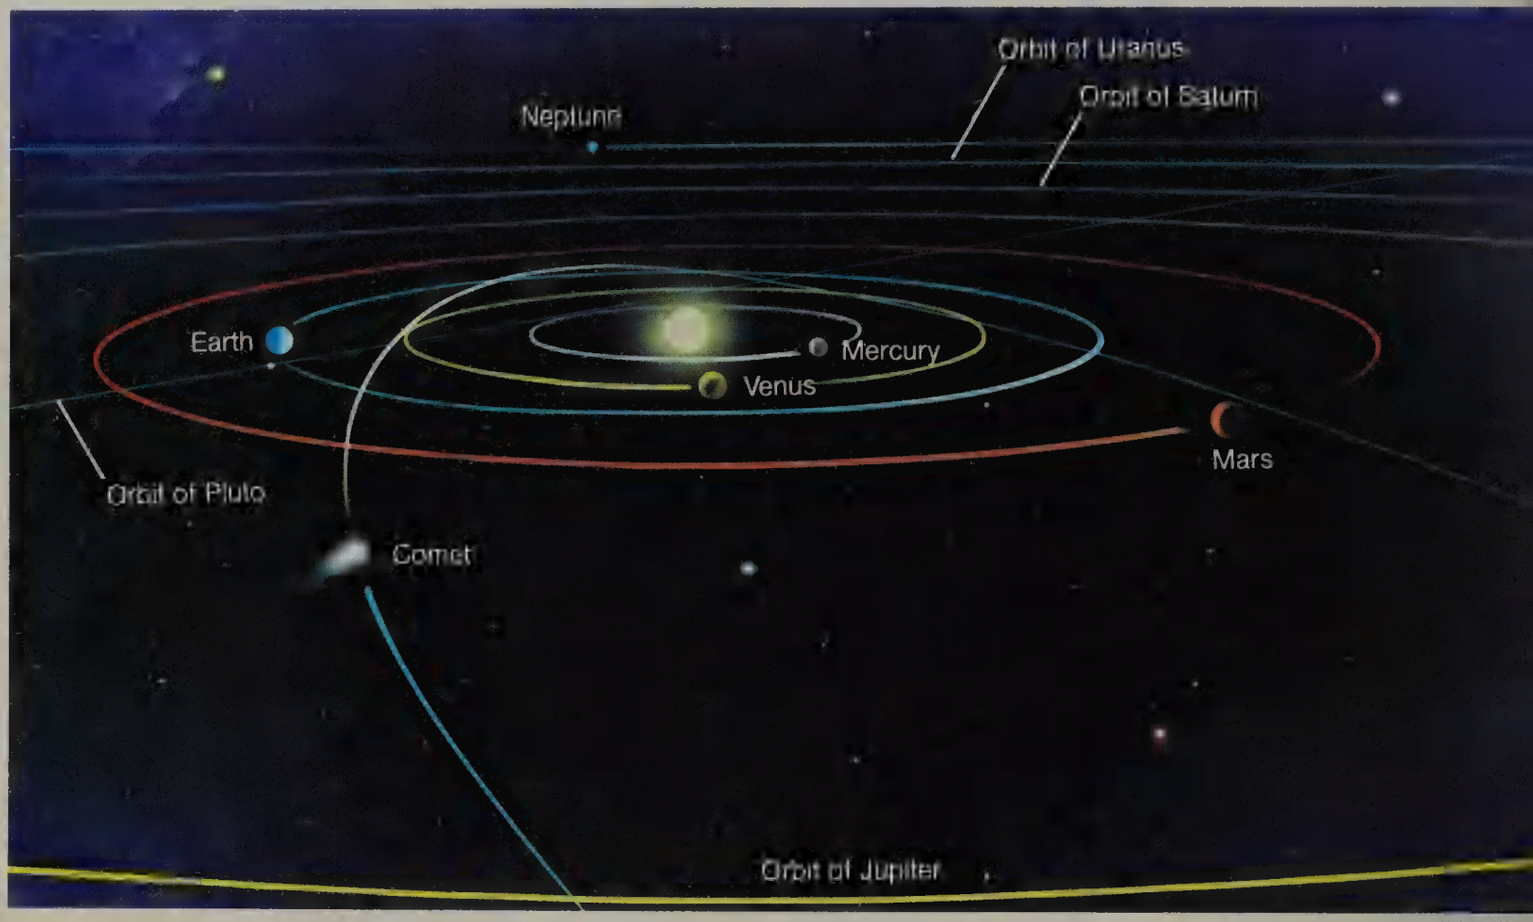
September 24–27: The gibbous moon widens nightly as it slips through Capricornus, Aquarius, and Pisces on the route toward the vernal equinox.

September 27: The equinox (which implies that day and night are of equal length) took place some days ago, but it is today that the interval between sunrise and sunset is exactly twelve hours. Of course, if you include twilight, the sky is light for more than twelve hours.

September 28–29: The full moon of the 28th, at 2:08 P.M., EST, is the harvest moon because it is so close to the vernal equinox. Moonrise occurs so near to sunset for the next several days that it appears as if we have a full moon right to the end of the month.

Editor's Note: The Sky Map in the July issue shows the evening constellations and stars this month and gives times for use

Halley's Comeback



Helmut Wimm

As Halley's comet circles the sun on a 7.2-billion-mile journey every seventy-six years, it traces a series of lazy loops in the earth's sky. Each spiraling loop takes about a year to complete, reflecting the earth's motion around the sun more than that of the comet. During the long series of seventy-five or so spirals, the loops drift slowly westward until suddenly the comet approaches the inner solar system and bursts across more than three-fourths of the sky in less than a year.

The westward dash begins this year on September 22. On that date, Comet Halley completes its final easterly (retrograde) jog in Gemini and swings westerly out of its last spiral, starting its spectacular eight-month sprint. From now until May 1986, the comet builds its coma and tail, swings around the sun, and loses them again, while twice coming close to the earth. On May 31, 1986, the comet turns easterly once more, beginning another long series of spirals that will not end until its next appearance in the year 2061.

This month the comet is still well beyond the distance to Mars; at midmonth it is 237 million miles from the sun and the same distance from the earth. It will be closer to the earth than to the sun from now until the year's end, months during which the earth and the comet close in toward one another.

Within the next month, Halley's comet will increase in brightness by more than five times, given the rapid pace at which the earth and the comet approach each other. By the end of the first week of November, Halley should be within range for binocular viewing, and from then until early January, Northern Hemisphere viewers will have their best shot at it.

History provides us with vivid accounts of Comet Halley's appearance, whetting our appetites for this one chance in a lifetime (for most of us) to see it. Unfortunately, history hasn't been completely honest with us. Although it records every appearance but one since 240 B.C., twenty-eight in all (with glowing accounts of some), the tradition of the spectacular comet we have inherited doesn't reflect the varying conditions that govern its visibility from the earth. Consequently, there remains some uncertainty over the comet's appearance this year. Historical evidence and the circumstances of its former journeys past the earth suggest that it will not be very bright or well placed for viewing in our sky. But despite the accuracy with which we can foretell their movements, comets are unpredictable at best. Data thus far indicate that Halley's comet may be brighter than predicted, although not greatly so.

But however poor the forecasts may be and whatever may happen, don't give up hope. Most likely, with enough effort, everyone who really wants to see this captivating object will be able to. Now is the time to prepare by dusting off your binoculars, getting out your star maps, and trying your hand at finding your way in the sky. In another month you can begin your own personal search for the most famous comet of history.

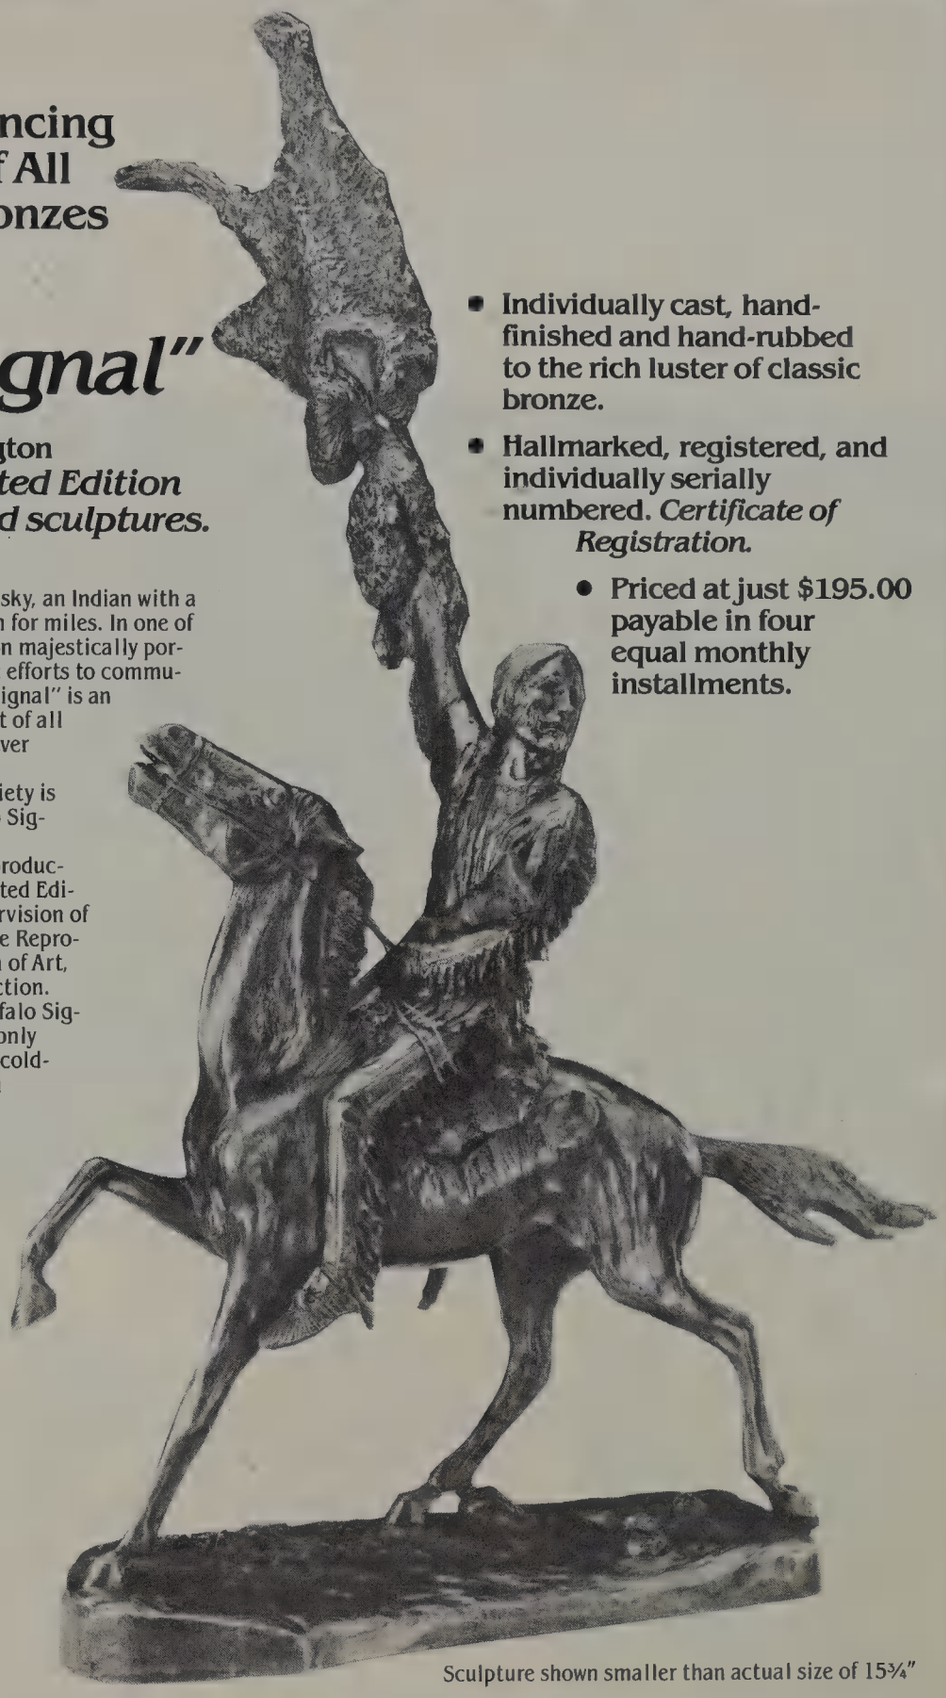
NE

Proudly Announcing The Rarest of All Remington Bronzes

"The Buffalo Signal"

by Frederic Remington

Issued in a single, Limited Edition of 9500 serially numbered sculptures.



- **Individually cast, hand-finished and hand-rubbed to the rich luster of classic bronze.**
- **Hallmarked, registered, and individually serially numbered. *Certificate of Registration.***
- **Priced at just $195.00 payable in four equal monthly installments.**

Starkly outlined against the vast Western sky, an Indian with a buffalo skin made signals that could be seen for miles. In one of his most powerful works, Frederic Remington majestically portrayed the intensity of the Indian's dramatic efforts to communicate across endless spaces. "The Buffalo Signal" is an exceptional masterpiece. It is also the rarest of all Remington bronzes. Only one original was ever cast.

And now, the New England Collectors Society is proud to announce the issue of "The Buffalo Signal" by Frederic Remington in a beautifully crafted, one-third size, museum quality reproduction of cold-cast bronze. This exclusive Limited Edition has been created under the direct supervision of Ms. Christine Roussel, former Director of the Reproduction Studio of the Metropolitan Museum of Art, and advisor to the Nelson Rockefeller Collection.

Each individually serially numbered "Buffalo Signal" in the permanently Limited Edition of only 9500 sculptures will be individually cast in cold-cast bronze. This modern sculpting medium holds even finer detail than traditional hot-casting. The work will then be meticulously hand-finished, and painstakingly hand-rubbed to the lustrous patina of classic bronze.

Each "Buffalo Signal" is also hallmarked, registered and accompanied by a Certificate of Registration. It is a stunning work of art clearly destined to be a treasured family heirloom.

To order your "Buffalo Signal" simply complete and return the reservation application. *No money need accompany your order at this time.*

The New England Collectors Society is a subsidiary of Reed & Barton Silversmiths, makers of fine products since 1824.

The Beetle With a Boring Head

Ray Mendez spotted this brentid beetle while cruising around one of his favorite Trinidadian locales—the backyard of the Asa Wright Nature Centre. The beetle had come into some flowers growing near the center's bamboo patch and then climbed up on one, possibly to chew some pollen. Mendez marveled at the engineering job that was its head. The whole front portion of the animal was head—a long stalk that narrowed, threw off a couple of antennae, and ended in two tiny jaws. It swiveled smoothly, as if moving on a ball bearing. Mendez could see it swiveling, too, for the animal, while very slow and mechanical and regular, never actually stopped moving.

According to Walter Linsenmaier, a German zoologist, brentid beetles (sometimes called giraffe beetles) often have long heads and faces that project forward, like the trunk of an elephant, "to grotesque lengths." The brentids use them to bore into plants or fruits they eat, but even more often, they use them to drill into wood or bark so they can lay their eggs. According to Linsenmaier, the larvae then gnaw out shafts of their own and eat the fungi that pop up in them.

Mendez has observed this himself in Trinidad. He has often seen a congregation of beetles on a recently fallen tree. The sappy area in the cut of the tree seems to attract beetles, flies, and even moths and butterflies. At other times he has seen brentids nesting in the hollow stems of bamboo. In any case, this particular beetle never really stopped fidgeting, but somehow Mendez managed to get a couple of shots of it. Enlarged here, the bug looks a lot more fearsome than it does at the Asa Wright Nature Centre—where brentids rarely get to be more than a couple of inches long.

100% Merino Wool Mattress Pad

MANUFACTURER DIRECT

Soft 100% Merino Wool cushions and cradles your body for a deeper, more restful night's sleep. Even the best mattress creates pressure points on the shoulders, hips and back. Soft, thick Merino Wool conforms to the contours of your body, relieving pressure points. Many people report they fall asleep faster and enjoy a more restful sleep.

In an independent study of our wool pad conducted by the University of Wisconsin; 83% of the participants reported a better night's sleep, 94% stated their muscles and joints felt better the next day.

Wool is a natural insulator. In winter, the pad retains body heat to keep you warm. In summer, the pad keeps you cool by absorbing moisture. As an exclusive and superior design innovation, we have eliminated the standard elastic straps and have designed the pad like a fitted bottom sheet to hold the wool more firmly in place.

Machine Washable. Non-Allergenic.

If you don't enjoy the best night's sleep you've ever had, simply return the pad for a complete refund.

Delivery: We ship within 24 to 48 hrs.

Additional Readin

Dickson Mounds (p. 12)

Paleopathology and the Origins of Agriculture, edited by Mark N. Cohen and George J. Armelagos (New York: Academic Press, 1984), compares the health of prehistoric farmers with their hunter-gatherer forebears. A chapter by Alan H. Goodman et al., "Health Changes at Dickson Mounds, Illinois (A.D. 950–1300)," chronicles the effects of economic and cultural change on the health of prehistoric populations in this area. Robert Gilbert, Jr., and James Mielke edited *Analysis of Prehistoric Diets* (New York: Academic Press, 1985), a report on the methods used to interpret prehistoric nutritional stress. For a review of mankind's first three million years, see Robert J. Wenke's *Patterns in Prehistory* (New York: Oxford University Press, 1980).

Mongooses and Hornbills (p. 36)

In *King Solomon's Ring* (New York: Thomas Y. Crowell, 1952), Konrad Z. Lorenz speculates, among other things, that our own instinctive behavior has much in common with that of animals. Niko Tinbergen, the Dutch-born zoologist based at Oxford, introduces ethology as objective science in *The Study of Instinct* (Oxford: Clarendon Press, 1951). O. Anne Rasa's book *Mongoose Watch: A Family Observed* is scheduled to be published by Doubleday and Co., New York, in January 1986.

Butcher's Pioneers (p. 44)

Solomon D. Butcher's pictures constitute the most comprehensive photographic record of the pioneers who settled the Nebraska plains. Combining critical analysis with biography, John E. Carter's *Photographing the American Dream,* to be published by the University of Nebraska Press, Lincoln, in October, establishes Butcher's place in photography. Solomon D. Butcher's *Pioneer History of Custer County, Nebraska* (Broken Bow, NE: Purcell, Inc., 1976), a reprint of his 1901 photographic history of the area, is available from Harry Purcell, 1210 Holly Livermore, CA 94550 (hardcover, $15.50; paperback, $9, postage extra). Roger L. Welsch's *Sod Walls,* an analysis of sod house architecture as a form of folk art, was published by Purcell in 1980 ($10, paperback). Welsch derived much of his information from Butcher's photographs, as well as from people whose families lived in sod houses. Robert Ta *Photography and the American Scene* history of photography from 1839 to 18 was originally published in 1938 and printed by Dover Books in 1964. One the better articles written about Butche David Vestal's "S.D. Butcher of N braska" (*U.S. Camera Annual,* U Camera Publishing Corp., New Yo 1971).

Peripatuses (p. 54)

Michael Ghiselin's *The Economy Nature and the Evolution of Sex* (Ber ley: University of California Press, 19 is a refreshingly learned book that, cording to its author, "is a cross betwe the *Kama Sutra* and *The Wealth of N tions:* it seeks to explain the diversity of productive phenomena in the light some ideas derived from classical econo ics." *Living Fossils,* edited by Ni Eldredge and Steven M. Stanley (N York: Springer-Verlag, 1984), include short chapter by Ghiselin on the peri tus, reviewing the animal's taxonor ecology, and other aspects. Females larger than males in a majority of anir species, including the peripatus, for number of reasons; Stephen Jay Gou looks at these in "The Oddball Hum Male" (*Natural History,* July 1982, 14–22). Gould's "Sex and Size" (*Natu History*, August 1983, pp. 24–27) exa ines a general phenomenon in nature—s change—and ponders why the pattern changing from male to female, rather th from female to male, is more common.

Ants and Treehoppers (p. 62)

Catherine M. Bristow's "Treehopp Transfer Parental Care to Ants: A N Benefit of Mutualism" (*Science,* vol. 2 pp. 532–33) is one of the few articles these insects that isn't extremely techni or mainly concerned with their system ics. A new edition of A.F.G. Dixo *Aphid Ecology* (London: Blackie/N thuen, 1985) includes a readable review the phloem-feeding insects, closely rela to treehoppers. E.O. Wilson's *The Ins Societies* (Cambridge: Harvard Univ sity Press, 1971) treats ant–aphid inter tions, and John N. Thompson's *Inter tion and Coevolution* (New York: Jo Wiley and Sons, 1982) is one of the f books that deals with mutualisms and h they evolved.

Alan H. Goodman (page 12), a Bost Red Sox fan, and **George J. Armelag** a Detroit Tigers fan, put aside their d ferences long enough to study the ske tons of prehistoric Native America buried at Dickson Mounds, Illino Their aim has been to see how the adve of agriculture affected the health these early people. Goodman was o of a number of graduate students w worked on this research under the gui ance of Armelagos, a professor of a thropology at the University of Mass

ts at Amherst. Armelagos is now
ng diet and disease among pre-
c Nubians in the Sudan. Good-
s a visiting assistant professor of
cal anthropology at Hampshire
e, in Amherst, and a postdoctoral
at the University of Connecticut
l of Dental Medicine and Depart-
of Nutritional Sciences. His
t work includes using dental de-
as indicators of fetal, infant, and
ood physiological stress in con-
rary groups in rural Mexico.

John E. Carter (page 44) has a passion for the Great Plains (generally) and the state of Nebraska (specifically). "Almost all my time is spent studying and interpreting Nebraska culture. I am one of those fortunate few," he says, "who manages to get paid for his avocation, hobby, and diversion." As curator of photographs for the Nebraska State Historical Society, Carter has access to the Solomon D. Butcher Collection of glass plate negatives—the pride of the Society's photographic holdings. "I was struck by the fact that no serious analysis of Butcher's life or work had been done," he observed. "The book from which this article is excerpted represents five years of research on my part and is a serious attempt to locate Butcher in the history of the American West as well as in the history of photography."

R. Bruhn

O. Anne Rasa (page 36) has been studying the behavior, sociology, and ecology of Africa's dwarf mongooses for fifteen years; the unusual and unexpected mutualism between the mongooses and some hornbills first caught her attention in 1980. A Heisenberg Scholar at the University of Bayreuth in West Germany, she spends four months of every year in the Taru Desert of Kenya. Next year, Doubleday will publish the results of her mongoose studies in *Mongoose Watch: A Family Observed*. Rasa describes herself as a "naturalist interested in all aspects of plant and animal ecology in Europe and Africa, especially those relevant to conservation." She is particularly concerned about the fate of "birds and small mammals, which are overlooked in most conservation projects." Rasa does not restrict herself to smaller animals, however; she also breeds and shows Welsh cob horses.

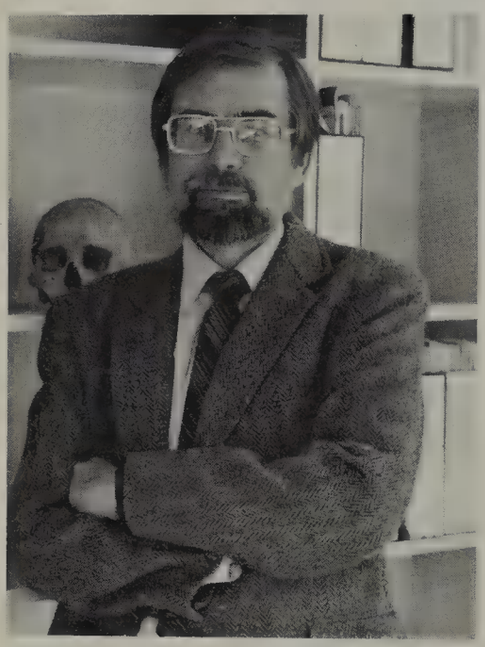
Authors *(continued)*

While doing research for his book *The Economy of Nature and the Evolution of Sex*, **Michael Ghiselin** (page 54) unearthed information on modes of reproduction in various animals, among them the living fossil *Peripatus*. Ghiselin's career has taken him to the academic realms of Stanford, Harvard, and Berkeley (among other schools) and into the field in the Malay Archipelago, Palau, the Caribbean, and Mexico. His *Triumph of the Darwinian Method* is perhaps the most widely known of his works. Future projects include further investigation of the mechanisms of natural selection, in particular the evolution and classification of sea slugs. An invertebrate specialist, Ghiselin was awarded a MacArthur Prize Fellowship in 1981 and is now a research fellow at the California Academy of Sciences in San Francisco.



Treehoppers, the sugar cows of the insect world, which are protected and "milked" by ants, have interested **Catherine M. Bristow** (page 62) since she was a graduate student at Princeton. Her initial interest was in the predators of treehoppers and aphids, which also excrete sugar. But you can't watch these bugs' predators without also noticing the ants, since the ants violently attack anything that remotely threatens the flow of sugar. So after a while, Bristow forgot entirely about the predators and focused instead on the mutualistic relationship between ants and sugar producers. As she points out in her article, treehoppers are not as passive as they might seem—they have evolved ways to exploit the ants' sweet tooth. Bristow's newest interest, however, is the setting for this phenomenon—the host plant. She speculates that it may have an important role in mutualism. "If ants are so beneficial, why are so few aphids tended?" she asks. "What effect does the plant species have on an aphid's ability to attract ants?" Bristow is currently based at the University of California, Davis.

Zoologist **Morley Read**'s first meeting with a peripatus (page 56) was a case of pure serendipity. He encountered the animal in Trinidad in 1978, while searching a rotting log for reptiles. Since then, he's gotten to know the "walking worm" quite well and is completing his doctoral project on peripatus feeding behavior. Read is a research student at the University College of North Wales, but his work has taken him to Brazil, the Lesser Antilles, and Tobago, as well as Trinidad. When not stalking peripatuses on tropical stream banks, Read captures natural history subjects on sound recordings and film. His footage has been broadcast on such popular BBC television series as "Life on Earth" and "The Living Planet."

EASTERN AND THE AMERICAN EXPRESS® CARD CAN HELP YOU SAVOR SOUTH AMERICA.

In South America, the local cuisine is as fascinating to explore as the local scenery.

In fact, the food is so appealing, you may think the old adage "travel is broadening" refers to your waistline as well as your mind.

But never fear. In South America, you can work off the pounds by hiking to see the ruins, touring cities filled with masterpieces of baroque architecture, jogging along sandy beaches, skiing down the world's highest slopes and dancing to the beat of another South American creation: the tango.

And because of Eastern Airlines, you won't have to spend as much money as you think.

Eastern can fly you to more of South America from more of North America than any other airline. As well as to Panama, Guatemala and Costa Rica. With packages that make your vacation affordable.

For more facts, see Eastern or your Travel Agent.

And be sure to charge your South American trip with the American Express® Card—which is welcomed almost everywhere. Use it for shopping, nightclubbing and dining in fine restaurants. It shows you have terrific taste. Don't leave home without it®

With Eastern and the American Express Card, you can enjoy a vacation that's fulfilling in every way.

The American Express® Card. Don't leave home without it®

Lazy Beds and Washerboard Ridges

"One Potato, Two Potato," by John Omohundro (June 1985), documents well the ecological soundness of "lazy bed" cultivation in Newfoundland. Lazy beds are an efficient system for potato gardening, providing drainage, warmth, and high yields per acre in marginal environments. Such benefits are not restricted to Newfoundland but are found throughout the Celtic fringe of Europe (Ireland, Scotland, and elsewhere) even today.

Lazy beds were an integral part of Ireland and Scotland's combined tillage and grazing economy, which became increasingly dependent on potatoes after 1700. In this mixed agrarian context, lazy beds provided another, subtle benefit to rapidly expanding rural populations. When farmers allowed lazy bed plots to go back into grassland, the beds crumbled and eroded into soft, washerboard-like ridges. These ridges effectively increased the surface area of grassland where the lazy beds had been. In any particular plot, the surface area increased by 5 to 15 percent, depending on the erosion pattern. Thus, more grass was produced by the plot of land.

In nineteenth-century Ireland, the surface area expansion caused by old lazy beds was not restricted to small plots; in some cases, entire village hinterlands were transformed. Many of these areas may still be seen today. An extreme example of "washerboard" land is on the slopes of Killary Harbor, a deep valley in County Mayo. The ridges are fossil testimony to the struggles of farmers who survived the famine and postfamine decades.

Eric Almquist
Belmont, Massachusetts

Who's Stung?

In "Anatomy of a Sting" (July 1985), Jim Robbins understates the importance of the Peregrine Fund to survival of the peregrine as much as he overstates the importance of illegal taking in saying that the Fund has "already raised several hundred birds and released them into the wild." The actual number at the end of 1984 was about 1,400, and several hundred more have been released in 1985. Robbins also reports, without evaluation, Fish and Wildlife Service accusations against the Peregrine Fund that originated with the German Lothar Ciesielski and appear to be based on nothing but hearsay and conjecture. It is not only disconcerting that the Law Enforcement Division of the Fish and Wildlife Service has been broadcasting derogatory statements from a source of such dubious credibility, thus risking serious damage to the Peregrine Fund's effective program to restore an endangered species, but also that Robbins has been willing to spread them further. If those statements cause even a 10 percent decrease in donations to the Peregrine Fund, the Service will have done more damage to the wild peregrine population by reducing the rate of release of captive-bred peregrines to the wild than all the illegal taking described in the Service's claims—claims we believe to be greatly exaggerated.

Williston Shor
North American Falconers Association
Mill Valley, California

Jim Robbins replies:

I took great pains to point out that the information on the Peregrine Fund was hearsay. Because the reputation of the Fund had already been damaged to the point that it had lost funding, I felt this was an opportunity for Fund officials to air their side of the story. In my mind, the Peregrine Fund remains a professional organization that is crucial to the restoration of the peregrine falcon in the Un States.

In Good Odor

In "Stowaways on the Hummingl Express" (July 1985), Robert K. Col denigrates the human sense of smell. F he read Trygg Engen's 1982 book, *Perception of Odors*, Colwell would k better. The human nose is exquisitely sitive to many odors and plays an im tant (if generally misunderstood) rol human affairs. One reason we tend to derestimate the importance of olfact Engen notes, is that most sensory input the nose go directly to the emotional c ters of the brain, not to the cortex. Th the influence of smells on human cho and activities is typically unconscious.

James V. McCon
Ann Arbor, Michi

Robert K. Colwell replies:

As a lover of wine, food, and cook and as a firm believer in the role of hun pheromones in daily life, I certainly not intend to "denigrate" the human se of smell in any absolute sense. Nonet less, an hour spent watching coatimun in a tropical forest, or even just a walk the woods with the family dog, is olfactorily humbling experience. Hum perception of odors is without doubt derrated, but isn't it curious that we one who cannot see "blind," and one w cannot hear "deaf," yet there is no w in our common speech for the inability smell?

The contrast I intended in "St aways," however, was not so much tween human and other animals, but tween the sensory world of hummingb flower mites—which see nothing—a the sensory world of hummingbirds which smell nothing (as far as we kno

Fifty Years of Astronomy

Hayden Planetarium reaches the half-century mark

by Isaac Asimov

In October 1935, the Hayden Planetarium opened. Astronomy seemed a highly developed subject. There were huge telescopes. Distant Pluto had been discovered. The universe contained vast numbers of galaxies, each as crowded with stars as our own Milky Way, and the whole of it was expanding. It seemed there was little more to expect.

As it happened, however, astronomy was entering its golden age. Fifty years of revolutionary development lay ahead. So much has taken place that we can only sketch the major developments here.

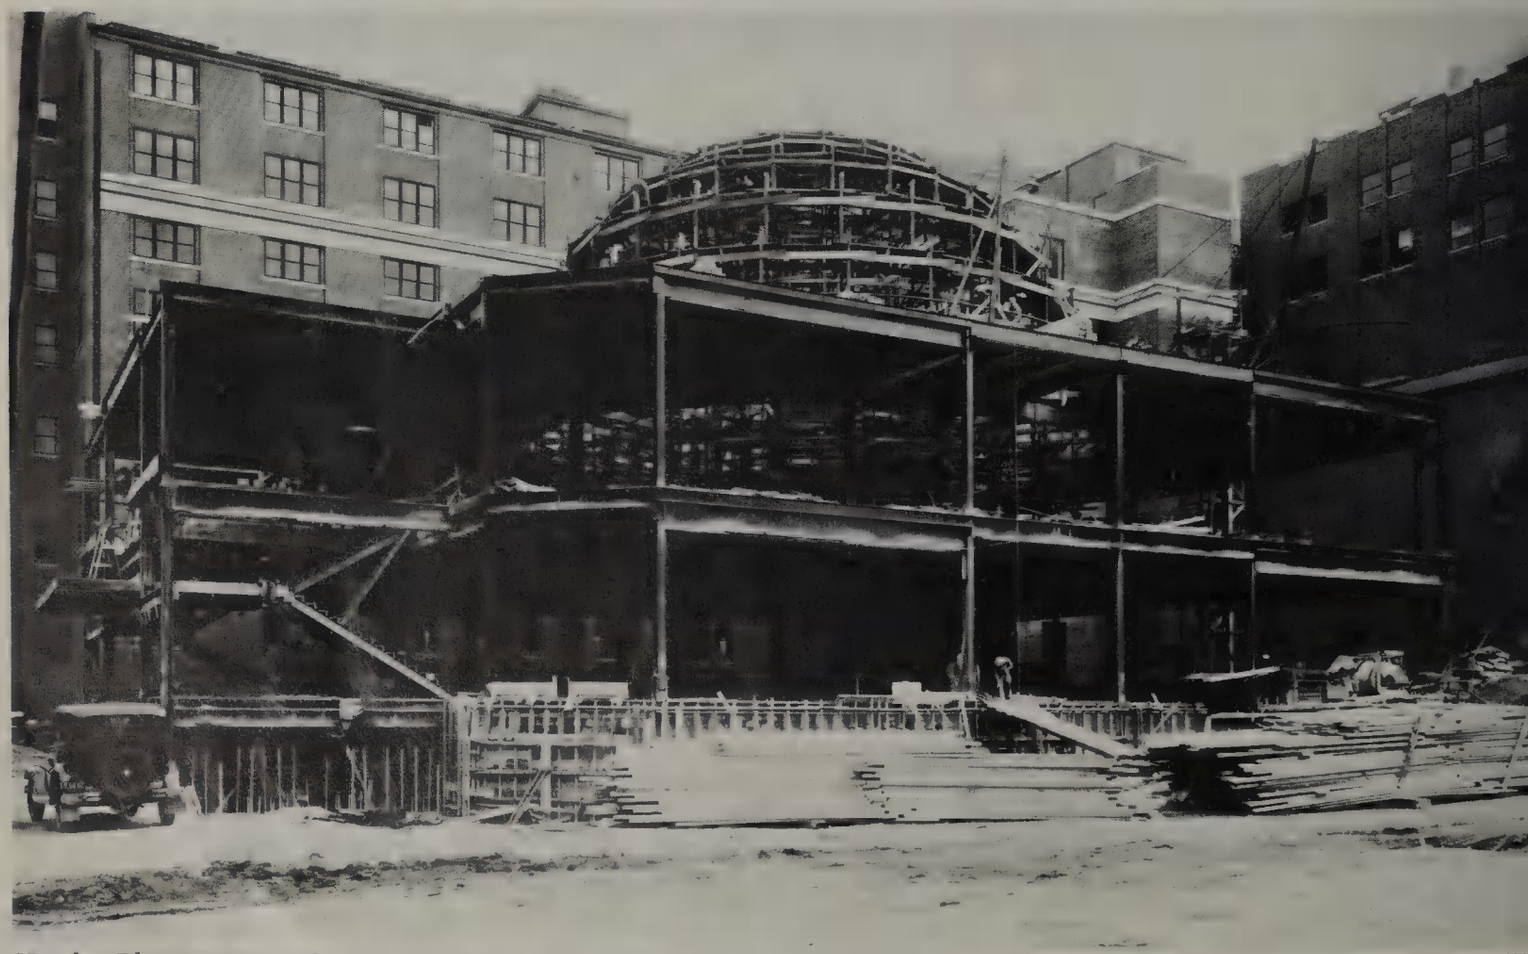
The most familiar astronomical body is, of course, the earth itself, but in 1935 we knew surprisingly little of its geological development. In 1953, however, the Great Global Rift was discovered, and with time it came to be realized that the earth's crust consisted of half a dozen large plates, with a number of smaller ones, all well fitted together and all in very slow motion. It was these plates and their motions (plate tectonics) that accounted for mountain building, island chains, earthquakes, and volcanoes. They even helped explain the course of evolution.

Human beings hurled themselves off the earth, too, something no one but a few science fiction writers took seriously in 1935. The first artificial satellite was launched in 1957. A probe went around the moon in 1959 and sent back the first photographs of the far side, something no human being had ever seen until then. Eventually, the entire moon was mapped in as nearly great detail as the earth is.

In 1961, the first man was placed in orbit, and in 1969, the first men set foot on the moon. Eventually, many pounds of moon rocks were brought back to the earth, and the moon became part of the human range.

The advent of rockets and probes advanced our knowledge of the solar system as has nothing else since the invention of the telescope. For three-quarters of a century, it was thought that Mercury and Ve
nus faced one side to the sun at all time
and had days as long as their years. I
1965, radar reflections from Mercury'
surface showed that it revolved in two
thirds of its year. Every portion of its su
face had both day and night. Similar stud
ies of Venus showed that the length of it
day was *longer* that that of its year an
that it rotated in the "wrong" directio
from east to west. Moreover, microwav
radiation from Venus was detected an
gave the first hint that it was hotter tha
had been thought. The surface tempera
ture throughout the planet is hot enoug
to melt lead so that there is no liquid wate
on it. Its thick, unbroken cloud layer
composed of dilute sulfuric acid, and i
atmosphere, ninety times the density
the earth's, is mostly carbon dioxide.

Probes have mapped most of Mercury
surface in detail, and radar observatio
has mapped Venus's surface rathe
crudely. Probes have also studied Ma



Hayden Planetarium under construction in 1934, one year before it opened

and, in 1976, even landed on it. The long dreamed of canals of Mars do not exist, but craters do. (Indeed, craters exist on every airless world, with a few understood exceptions.) Extinct volcanoes also exist on Mars (and possibly on Venus). Mars's atmosphere is one percent as thick as the earth's and is mostly carbon dioxide. Its temperature is as low as that of Antarctica. Analysis of Martian soil makes it doubtful that any life exists there.

Finally, probes have taken photographs of Jupiter and Saturn at close quarters and shown us those giants in far greater detail than could be hoped for from Earth-based observations. In a way, the surroundings of the planets were the subject of more startling discoveries than the planets themselves were.

Jupiter was surrounded by a giant magnetic field containing charged particles that would make human exploration extremely difficult, if not impossible, and it also possessed a thin ring of debris invisible from the earth. Ganymede and Callisto, its two giant outer satellites, were cratered and icy. Europa, the smallest of the four giants, was covered with a worldwide glacier, crisscrossed by cracks, and probably had a liquid ocean beneath. Io was the great surprise. It had active volcanoes that spewed out sulfur so that the surface was red-orange in color.

The great surprise in connection with Saturn was its rings, which turned out to be extraordinarily complex, being made up of hundreds or even thousands of concentric ringlets. Dark "spokes" were present, and some of the ringlets even seemed "braided." Much of the detail of the rings remains to be explained. Titan, the largest Saturnian satellite, was thought, from Earth-based observations, to have a thin, methane atmosphere but was found to have one that was smoggy, half again as dense as the earth's, and consisting mostly of nitrogen.

Probes have not yet reached beyond Saturn, but since 1935, Earth-based studies have discovered a fifth satellite of Uranus and a second satellite of Neptune. In 1977, a large asteroid, Chiron, was discovered, with an orbit that carried it from the neighborhood of Saturn out to that of Uranus. In 1978, Pluto was found to have a satellite, named Charon, almost as large as the planet itself. Pluto turned out to be far smaller than it was thought to be when first discovered. It is considerably smaller than our moon.

In 1935, the source of the sun's energy still had an air of mystery about it. In 1938, however, the details of the hydrogen fusion at its center seemed to have been worked out.

In 1958, it became clear that a constant spray of rapid charged particles was emerging from the sun in all directions, the so-called solar wind. Also emerging from the sun in all directions are particles called neutrinos (which were only mentioned in theory in 1935 and which very few took seriously). These solar neutrinos emerge from the fusion regions at the center and could tell us a great deal about the workings of the sun if they could be properly trapped and studied. Attempts were made in the 1970s and 1980s, but so far, only one-third of the expected number of neutrinos have been found—which may mean that we don't yet have the correct information about what goes on in the center of the sun.

Another point of uncertainty concerning the sun is the verification of the Maunder minimum, which had first been suggested back in the 1890s but which no one then took seriously. Apparently, the sun goes through decades-long periods in which there are virtually no sunspots. This evidently affects the earth's weather, for the last Maunder minimum (1645 to 1715) seems to have coincided with a siege of unusually cold temperatures. We must therefore take seriously the effect upon us of a sun far less stable and well behaved than it was thought to be in 1935.

In studying the universe outside our solar system, we began by being dependent only on the light radiated from the stars. Although astronomers developed the use of telescopes, spectroscopes, and cameras, the basic information still came from light—even in 1935, when the Hayden Planetarium was opened.

To be sure, radio waves from the stars were discovered in 1931, but it was not until after World War II that the technique of detecting such waves was sufficiently developed to make radio astronomy a important branch of the science.

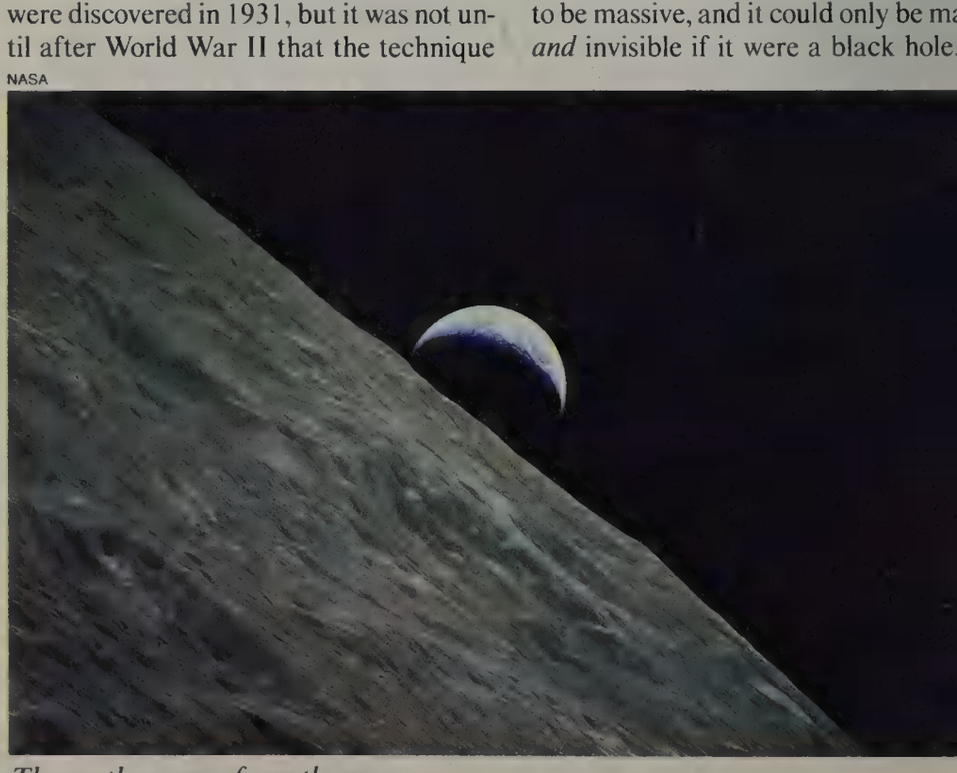
In 1969, an entirely new kind of was detected through radiotelesc Rapid radio pulsations with a period i second range were discovered and see to originate in what were called puls stars, or pulsars. More and more of were detected in the sky, and a cons ation of the properties of those pulse to the realization that pulsars were tron stars.

Neutron stars had first been spok as possible out of purely theoretical soning in 1934, a year before the Ha Planetarium was founded, but they not taken seriously. Now they are k to exist. They are extremely compr stars, the remnants of supernova e sions, made up of neutrons in conta that a star of the mass of our sun wou condensed into an object only about miles across.

An even more condensed object w be a black hole. This would be a sta any object) that would be condens the point where even neutrons w smash together and break down so the resultant matter would collapse t volume (a "singularity"). The existen black holes was first suggested in but there was no chance of detectin until satellites were designed launched beyond the earth's atmos for the purpose of picking up X-rays space.

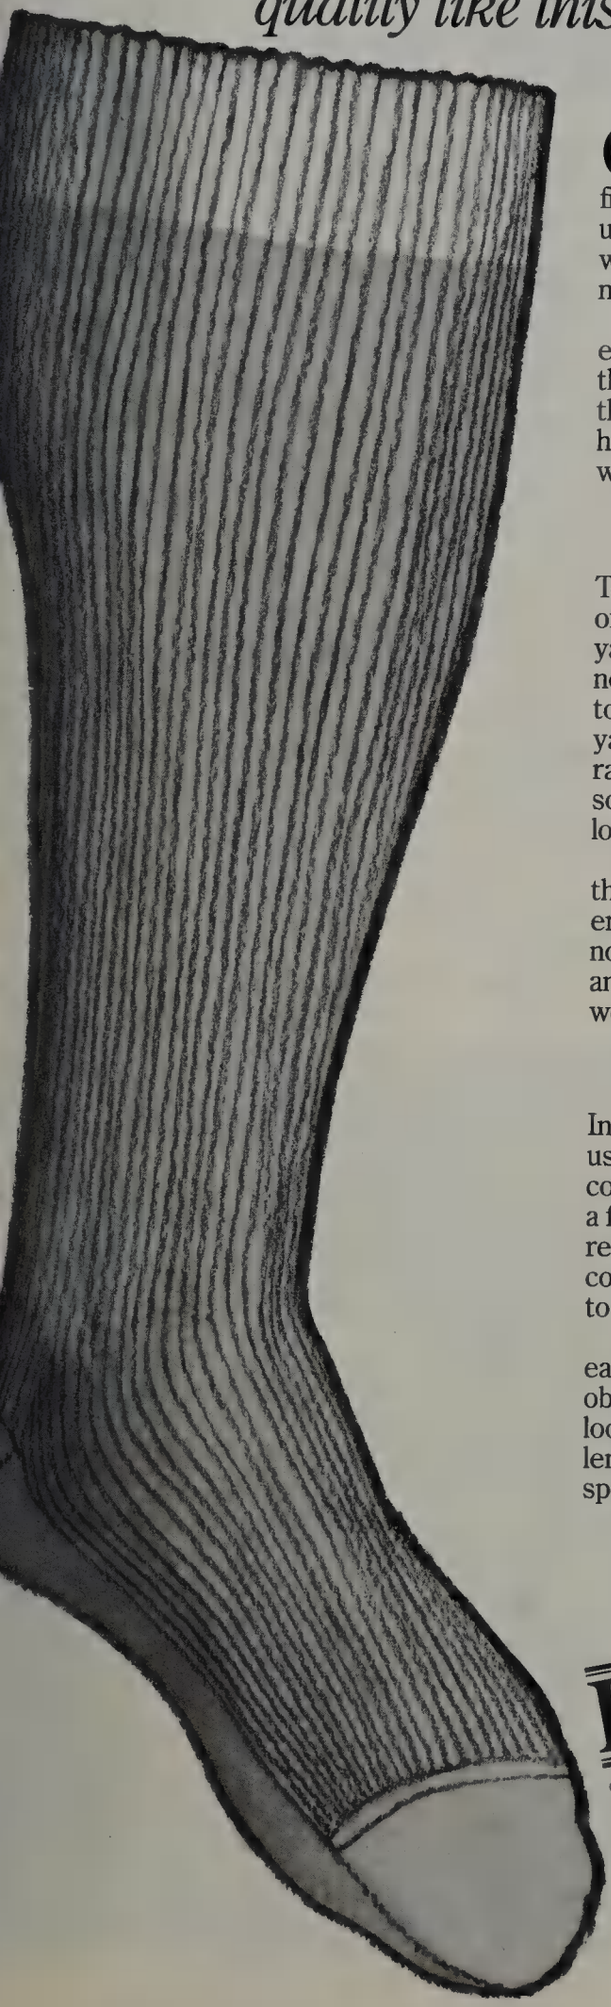
In 1971, an X-ray source called Cy X-1 was found to be an invisible obje cling a massive star. From the natu the orbit, the X-ray source was itself to be massive, and it could only be ma *and* invisible if it were a black hole.

NASA



The earth as seen from the moon

Before you say $11.50 is too much to pay for these Lands' End socks, remember: *quality like this comes only from France.*



Our search for the finest quality men's sock we could find—the kind of search typical of us at Lands' End—took us all the way to the Dore Dore knitting mills in France.

Here, with a skill no longer easy to come by in this country, this fine mill is turning out some of the most comfortable socks we have ever worn. And a value even with a price tag in double figures.

To be a little more specific...

To begin with, this sock is knitted of natural fibers—from plied yarn, not single strands, to make not only for a smoother finish but to provide durability, too. It is yarn-dyed, strand by strand, rather than piece-dyed, sock by sock. This is to assure truer, longer-lasting color.

In the circular knit process the manufacturer uses, he employs more needles than normal to produce a denser knit and provide more support, longer wear and better shape retention.

Toes are deftly closed by hand.

In closing the toe, each knitter uses a "blind loop" technique comparable to that used in making a full-fashioned sweater. The result: seamless, luxurious comfort—particularly conducive to wiggling your toes.

As if this weren't enough, each individual sock is tested for obvious defects like missed loops, weak yarns, uneven lengths, a lack of elasticity. (And speaking of elasticity, the elasticized top of the sock clings to the calf—never tiring of its assignment halfway through its sock-life, like so many elasticized sock tops do.)

The Dore Dore sock is knitted of 63% wool on the outside rib, for warmth; of 37% cotton on the inside, for absorbency and comfort against the skin. So, even though it's a somewhat thicker sock than most, it can be worn comfortably year-round. All fibers are anti-allergenic, and of course, heels and toes are reinforced.

To this, add our guarantee.

When we import these socks, they still have to pass our Quality Assurance people before they qualify for space in our Lands' End catalog, and earn our unconditional guarantee.

That guarantee, mind you, is so unconditional we express it in two words: GUARANTEED. PERIOD. No ifs, ands, buts or maybes.

If all this seems like more than you want to know about socks, consider that the same search for quality and value applies to everything we offer you at Lands' End —wherever in the world we find it—from soft luggage, to clothing, to accessories—right down to your toes, obviously.

Why delay any longer? Call our 24-hour-a-day toll-free number (800-356-4444). Or send us the coupon below.

Enjoy shopping the Lands' End way as millions of people like you already have.

Radio astronomy has shown that many galaxies are "active"; that is, they are unusually strong radio emitters. Such emissions tend to come from various jets extending from a galaxy's center. Some galaxies actually seem to be exploding. Even quiet galaxies, such as our own, have concentrated spots at the center that emit radio-wave radiation in considerable quantities. Apparently, black holes may exist at the center of most, if not all, galaxies, and even, possibly, at the center of globular clusters.

Under those conditions, the placid appearance of the night sky as seen by light alone, whether by eye or telescope, is, in a sense, a sham. By means of instruments that have only become available to us in the last generation, the universe appears to be an unimaginably violent place. It may even be that in most areas life as we know it would be impossible, and we are alive only because our sun circles the galactic center in an orbit that keeps it safely in the spiral arm outskirts.

Some radio sources seemed at first to be rather dim stars in our own galaxy, and this made them unusual indeed since the vast majority of stars did not emit detectable quantities of radio waves. Astronomers suspected, therefore, that they were something more than stars, and they were named quasistellar (that is, starlike) radio sources, or, for short, quasars.

In 1963, these quasars were found to be far more than they seemed to be, for their peculiar spectra turned out to consist of lines shifted unbelievably far toward the red. These enormous red shifts meant that quasars are tremendously far away—a billion light-years and more. They are, in fact, farther off than any of the visible galaxies and are the farthest objects known. Some quasars are more than ten billion light-years away from us.

Some pulsars exist in pairs and revolve about each other. Some quasars exist behind galaxies that lie between us and them. The manner in which pulsars, under such conditions, slow down and quasars, under such conditions, yield images that seem to split in two or more parts offers proof that Einstein's general theory of relativity is correct. This is excellent evidence, yet it involves objects not known to exist at the time that Einstein evolved his theory.

As for the universe as a whole, it was known as far back as 1935 to expand, and there was a suggestion that it began many billions of years ago in the form of a giant explosion. This big bang, however, had no real evidence to support it, and in 1948, a competing theory of continuous creation (the slow creation of matter that formed new galaxies between older galaxies that pulled away from each other) was introduced.

In 1949, scientists suggested that if the big bang had taken place, the fiery energies that existed at first would have spread out and cooled down as the universe expanded. Nowadays, those energies w
exist as radio-wave radiation co
equally from all parts of the sky—the
of radio waves that would be expecte
temperature near absolute zero.

In 1964, precisely this sort of r
wave radiation was detected, and nc
most all astronomers accept the big
theory of the beginnings of the univ
The details of the big bang are still u
discussion, however. The important
tions about the big bang deal with th
cific events that took place in the t
fractions of a second after the actua
ginning.

To understand those events, adv
had to be made in our understandi
the most basic particles of matter. I

"SMART MONEY" LIFE INSURANCE

HERE'S HOW TO PROTECT YOUR FAMILY NOW AND SAVE FOR FUTURE NEEDS, TOO—WITH ALLSTATE UNIVERSAL LIFE.

A lot of "smart money" people today are looking for a better way to buy life insurance.

They know they need life insurance for the same reason people have always needed it. If they die prematurely, it will provide money for their loved ones.

But these "smart money" people want *more* than the pure protection which term life provides. They also want to build cash values for their own futures— at currently, competitive interest rates.

Have It Both Ways with Allstate Universal Life.

If you're looking for that kind of insurance, you should look into Allstate Universal Life.

This policy will give your family the substantial protection you want them to have—without costing you an arm and a leg. But it gives you something more besides.

With this solid protection, you get *flexible interest*. Your rate is periodically adjusted up or down with current interest rates.

When our interest rates go up, you benefit. But when they go down you're protected. Allstate guarantees that your interest will never be less than 4.5 percent.

This Flexibility Meets Other Needs as Well.

Allstate Universal Life has other "flexibility" features "smart money" people find equally welcome.

Suppose you need a substantial amount of cash—to buy a bigger home, perhaps, or cover college tuition costs. You can borrow against those cash values you've been building up. Or you can take out some of the accumulated cash value to use as you wish.

Plus, if you're going through a money "crunch" you may be able to decrease or even skip your premium payments.

Within limits, policyholders who qualify can also increase face amount coverage. Or they can cut back to meet changing needs.

See How Much More You Can Get Out of Life.

Allstate will be glad to show you—in black and white—just what this policy can mean to your family's security and your own future.

Ask for all the facts on Allstate Universal Life—including your own individual computerized Cash Savings Outlook.

This personalized print-out can be a real eye opener, and it's yours free. So request yours today.

Then see for yourself—in dollars and cents how Allstate can help you get more out of life—and your life insurance dollars.

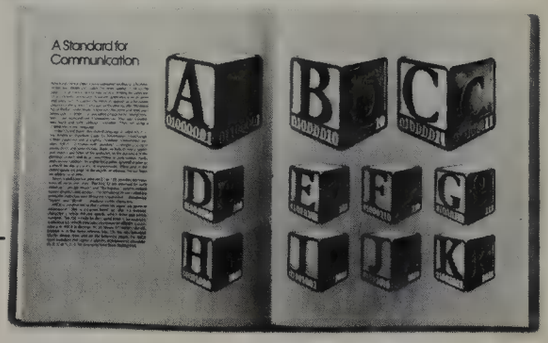
HOW NOT
AN ENDANG

TO BECOME
ERED SPECIES.

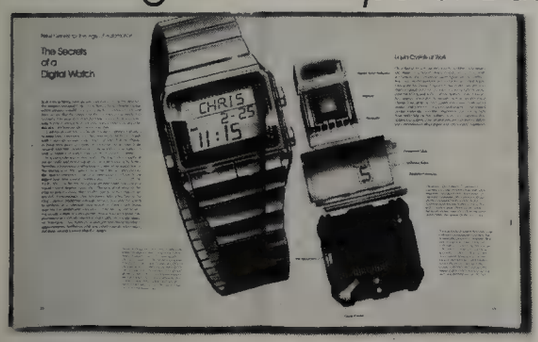
As more and more of our daily activities become "computerized," survival of the ttest will come down to this: Those who become successful will share a common nderstanding—a knowledge of computers.

That's why TIME-LIFE BOOKS brings you this brand ew series. UNDERSTANDING COMPUTERS does what vas once thought impossible. Help us understand ow computers do the impossible.



Through straightforward language (no "computer-se") and easy-to-follow illustrations, UNDERSTANDING COMPUTERS tells you what computers really are. ow to think about them. And how they can make your life easier—from where you vork to where you work out.

Starting with *Computer Basics*, you'll get a thrilling "inside view" of what happens inside that incredible black box.



You'll discover how everything a computer does can be reduced to a simple 'ON' or 'OFF,' like a switch. And you'll learn how computers can be taught everything from predicting the weather to teaching a foreign language to reducing your heating bills.

Step by step, your understanding will grow, until ou find yourself confident and at home in he Computer Age.

So end all your wondering and enjoy he wonder of it all. Examine *Computer asics* FREE for 10 days. If you aren't satis-ed, send it back and owe nothing. Other-vise keep it and pay just $12.95 ($15.95 in Canada) plus shipping and handling. Fu-ure volumes will come one about every ther month. Same free trial. Keep only the ooks you want. Cancel anytime.

Mail the coupon today. And see how asy understanding computers can be.

EXAMINE COMPUTER BASICS FOR 10 DAYS FREE.

UNDERSTANDING COMPUTERS

Not Necessarily a Wing

Which came first, the function or the form?

by Stephen Jay Gould

From *Flesh Gordon* to *Alex in Wonderland*, title parodies have been a stock-in-trade of low comedy. We may not anticipate a tactical similarity between the mayhem of *Mad* magazine's movie reviews and the titles of major scientific works, yet two important nineteenth-century critiques of Darwin parodied his most famous phrases in their headings.

In 1887, E.D. Cope, the American paleontologist known best for his fossil feud with O.C. Marsh but a celebrated evolutionary theorist in his own right, published *The Origin of the Fittest*—a takeoff on Herbert Spencer's phrase, borrowed by Darwin as the epigram for natural selection: survival of the fittest. (Natural selection, Cope argued, could only preserve favorable traits that must arise in some other manner, unknown to Darwin. The dilemma of evolution became, therefore, not the differential survival of adaptive traits, but their unexplained origin—hence the title parody.)

St. George Mivart (1817–1900), a fine British zoologist, tried to reconcile his unconventional views on religion and biology but ended his life in tragedy, rejected by both camps. At age seventeen, he abandoned his Anglican upbringing, became a Roman Catholic, and consequently (in a less tolerant age of state religion) lost his opportunity for training in natural history at Oxford or Cambridge. He became a lawyer but managed to carve out a distinguished career as an anatomist nonetheless. He embraced evolution and was befriended by the powerful T.H. Huxley, but his strongly expressed and idiosyncratic anti-Darwinian views led to his rejection by the biological establishment of Britain. He tried to unite his biology with his religion in a series of books and essays and ended up excommunicated for his trouble six weeks before his death.

Mivart shared Cope's major criticism of Darwin—that natural selection could explain the preservation and increase of favored traits but not their origin. But he went gunning for a higher target than Darwin's epigram. He shot for the title itself, naming his major book (1871) *On the Genesis of Species*. (Darwin, of course, had called his classic *On the Origin of Species*.)

Mivart's life may have ended in sadness and rejection thirty years later, but his *Genesis of Species* had a major impa its time. Darwin himself offered stro grudging, praise and took Mivart far seriously than any other critic, even ing a chapter to later editions of the *O of Species* primarily to counter Mi attack.

Mivart gathered, and illustrated admirable art and force" (Dar words), all objections to the theory o ural selection—"a formidable a (Darwin's words again). Yet one pa lar theme, urged with special attenti Mivart, stood out as the centerpiece criticism. It remains today the pri stumbling block among thoughtful

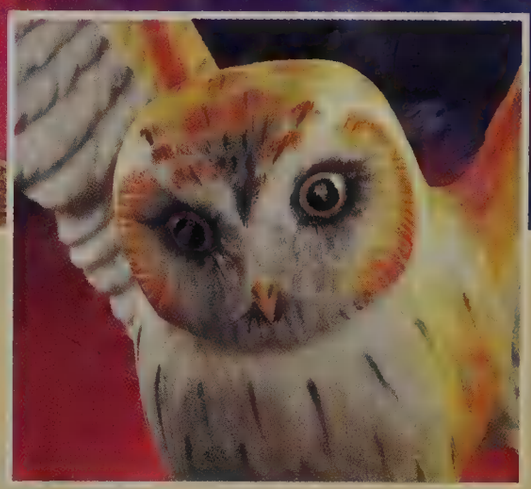
BOEHM...The Screech Owl
...in porcelain and bronze...An Investment in Beauty



Since the dawn of civilization man has vered the owl. This reverence is evident the splendid representation of the reech Owl created by the gifted artists the Boehm Porcelain Studio.

The name Boehm has been synony- ous with the fine art of porcelain bird ulpture since the Studio was founded Edward Marshall Boehm in 1950. ese sculptures have been admired, ac- imed and honored throughout the orld. Today they are found in over 115 useums, distinguished private collec- ns, royal palaces and embassies. Not ly is a sculpture by Boehm valued for incomparable artistry, it is an incom- rable collectible as well—*the Boehm Stu- holds the record for the highest price ever d for a 20th century porcelain at auction.*

The Screech Owl is the first in a collec- n of eight North American Owls com- ing the ancient art forms of porcelain d lost-wax bronze. By joining the deli- y of the finest Boehm porcelain with nobility and strength of pure Boehm nze, the Studio has revived an art m that has been a favorite of Emper- , Kings and Queens for over 2,000 ars.

To achieve the wealth of detail that has ways been the trademark of the Boehm Studio, requires demanding craftsmanship. The Screech Owl is created *entirely by the talented hands* of the artists and master craftsmen of Boehm—from design to sculpturing, to casting and painting, every detail must satisfy Boehm's dedication to excellence.

Limited to an issue of 9,500 for the world, the Screech Owl will bear the world **famous Boehm Hallmark,** permanently **attesting to its authenticity and origin.** The price for each Screech Owl is only **$135.**

In your home or office, or as a gift for a friend, the Boehm Screech Owl will be a focus of beauty, a source of interest and admiration and a **collectible of the future.** To acquire this original porcelain sculpture, mail the attached application at your earliest possible convenience.

RESERVATION FORM

The North American Screech Owl
in Fine Boehm Porcelain and Pure Boehm Bronze

Boehm Porcelain Studio
25 Fairfacts Street
P.O. Box 5051
Trenton, New Jersey 08638

I wish to place my reservation for the original porcelain and bronze sculpture of The North American Screech Owl. My sculpture will bear the Boehm Hallmark attesting to its status as an original work of art from the Boehm Porcelain Studio.

☐ Enclosed is my full payment of $135.*
☐ Enclosed is my initial deposit of $45*. I will be billed for the remaining balance in two equal monthly installments of $45* each, beginning with the shipment of my sculpture.

**plus applicable sales tax*

friendly scrutinizers of Darwinism. I other criticism seems so troubling, so ob ously and evidently "right" (against Darwinian claim that seems intuitive paradoxical and improbable).

Mivart awarded this criticism a sep rate chapter in his book, right after the troduction. He also gave it a name, membered ever since. He called it "T Incompetency of 'Natural Selection' Account for the Incipient Stages of Us ful Structures." If this phrase sounds li a mouthful, consider the easy translatio we can readily understand how compl and fully developed structures work a owe their maintenance and preservation natural selection—a wing, an eye, the semblance of a bittern to a branch or of insect to a stick or dead leaf. But how you get from nothing to such an elabora something if evolution must proce through a long sequence of intermedia stages, each favored by natural selectio You can't fly with 2 percent of a wing gain much protection from an iota's sim larity with a potentially concealing pie of vegetation. How, in other words, c natural selection explain these incipie stages of structures that can only be us (as we now observe them) in much mo elaborated form?

I have treated this issue in many pre ous essays—and for a definite, impos reason. I receive an enormous volume mail from sincere and thoughtful reade who are trying to work through the co plexities of evolution and run adrift on o argument or another. (Often, of course cannot help because we professionals a adrift ourselves in many areas.) I ha made a semiformal tally of these reefs a shoals, and one point stands high abo the rest: the dilemma of incipient stag Mivart identified this problem as prima and it remains so today.

I take up this subject again for two re sons. First, I believe that Darwinism h and has long had, an adequate and int esting resolution to Mivart's challenge (though we have obviously been blessed unsuccessful in getting it across). Secon a paper just published in the technic journal *Evolution* has provided comp ling experimental evidence for this reso tion applied to its most famous case—t origin of wings.

The dilemma of wings—perhaps t standard illustration of Mivart's telli point about incipient stages—is set for particularly well in a perceptive letter th I received from a reader just last week medical doctor in California. He write

How does evolutionary theory as und stood by Darwin explain the emergence items such as wings, since a small move

rd a wing could hardly promote survival? eem to be stuck with the idea that a sig- ıcant quality of wing would have to ing forth all at once to have any survival ue.

Interestingly, my reader's proposal that ıch or most of the wing must arise all at ce because incipient stages could have adaptive value follows Mivart's own olution. Mivart first enunciated the ıeral dilemma (1871, p. 23):

tural selection utterly fails to account the conservation and development of the nute and rudimentary beginnings, the ght and infinitesimal commencements of uctures, however useful those structures y afterwards become.

After fifty pages of illustration, he con- des: "Arguments may yet be advanced favor of the view that new species have m time to time manifested themselves h suddenness, and by modifications ap- aring at once." Advocating this general ution for wings in particular, he con- des (p. 107): "It is difficult, then, to be- ve that the Avian limb was developed in y other way than by a comparatively lden modification of a marked and im- tant kind."

Darwin's theory is rooted in the proposi- n that natural selection is the primary ative force in evolutionary change. is creativity will be expressed only if the tuitous variation forming the raw mate- l of evolutionary change can be accu- lated sequentially in tiny doses, with ural selection acting as the sieve of ac- otance. If new species arise all at once in occasional lucky gulp, then selection s no creative role. Selection, at best, be- nes an executioner, eliminating the un- following this burst of good fortune. us, Mivart's solution—bypassing incip- t stages entirely in a grand evolutionary p—has always been viewed, quite htly, as an anti-Darwinian version of olutionary theory.

Darwin well appreciated the force, and entially devastating extent, of Mivart's tique about incipient stages. He coun- attacked with gusto, invoking the stan- rd example of wings and arguing that vart's solution of sudden change pre- ted more problems than it solved—for w can we believe that so complex a ucture as a wing, made of so many co- inated and coadapted parts, could se all at once:

who believes that some ancient form s transformed suddenly through an inter- force or tendency into, for instance, one nished with wings, will be . . . compelled believe that many structures beautifully

WHAT WORD TELLS YOU THIS IS A LONDON GIN?
(HINT: IT ISN'T THE WORD LONDON.)

A lot of gins have the word "London" on their labels. But that does not necessarily mean they are distilled in London, England.

Actually, there is only one major gin you can buy in the United States that is distilled, bottled and sealed—every last bottle of it—at the distillery in London.

The word that identifies that gin is Beefeater.®

THE YORK MINSTER CATHEDRAL CLOCK

Enjoy the satisfaction of building this classic collector's clock... *even if you've never done anything like it before.*

OR CENTURIES, collectors have taken ecial pride in displaying beautiful and-built clocks. Especially the 18th-ntury cathedral clocks that were built ith open faceplates to expose their ner workings. Handsomely crafted -with precision machined gears, pol-ed brass frames, and intricate strik-g movements—these "skeleton" ocks clearly show the skill of the aker. And today they are at a pre-ium; prized examples of the clock-aker's art.

Now, you can build a clock like this your own. One that chimes on the our—and can take its place in your me as a treasured family possession. nd you don't have to be a clockmaker do it.

All you need is The York Minster thedral Clock kit. A complete easy-use crafting kit—created by The anklin Mint Crafts Guild, and avail-le only from The Franklin Mint.

Everything you need — in one complete kit

ne design of this new clock is inspired one of England's most famous cath-rals—York Minster. Its etched brass ceplates reveal all the intricacies of e movement. The pendulum bob vis-e through open arches ... the ar-ngement of the gear train through fretted pillars ... a rachet and pawl escapement, and bell chime, at the top of the soaring towers. Finally, its ornate dial recalls the rose window that dominates the facade of York Minster.

And this precision-made kit includes everything—even special jeweler's tools. It arrives with all the component parts in separate compartments. And carefully written instructions that take the mystery out of clockmaking.

These instructions guide you step-by-step. Illustrations *show* you each step. You can work at your own pace, stop whenever you like—and pick up again right where you left off.

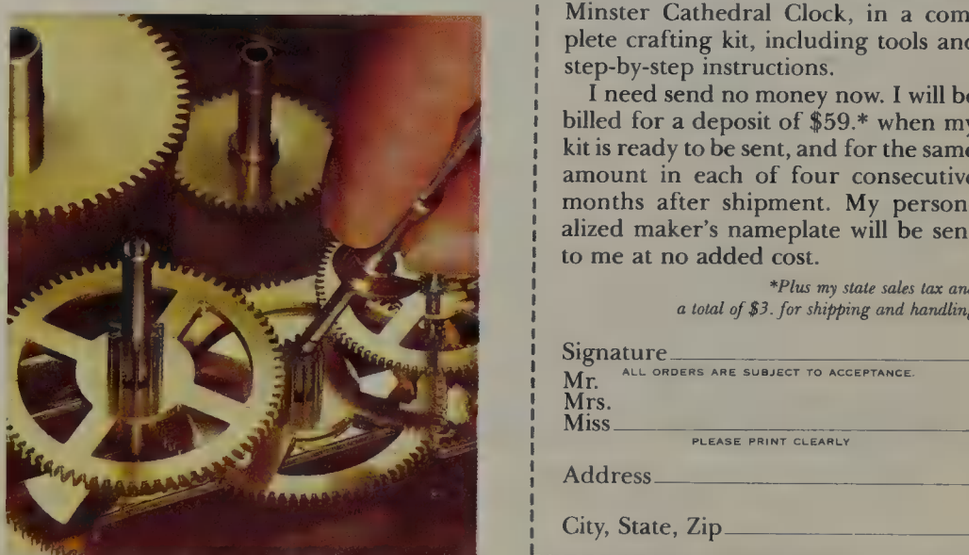
You'll also receive a maker's plate—with your name etched in brass—for the base of your clock. And a fascinating booklet that contains a glossary of terms, explains the movement, describes the gearing ... everything to make *you* the expert.

Quality, precision, beauty ... at an affordable price

On display, the quality of The York Minster Cathedral Clock will be immediately apparent. The 14-day key-wound movement is from West Germany—all brass, with a self-leveling pendulum for accuracy. The base is polished mahogany, and holds a protective glass dome. At jewelry stores, a hand-built clock like this can cost two to four times *more* than The York Minster Cathedral Clock kit—which is priced at $295, and payable in convenient monthly installments.

But of greater value are the creative rewards of building this heirloom clock on your own. And the compliments you'll receive.

To begin, simply complete and return the accompanying form. No payment is required at this time. But please be sure to mail your order form by October 31, 1985.



wn smaller than actual size.
e diameter: 7¾". Height (with dome): 11½".

true family heirloom you'll take pleasure in making yourself.

adapted to all the other parts of the same creature and to the surrounding conditions, have been suddenly produced; and of such complex and wonderful co-adaptations, he will not be able to assign a shadow of an explanation .... To admit all this is, as it seems to me, to enter into the realms of miracle, and to leave those of Science.

(This essay must now go in other directions but not without a small, tangential word in Mivart's defense. Mivart did appreciate the problem of complexity and coordination in sudden origins. He did not think that any old complex set of changes could arise all at once when needed—*that* would be tantamount to miracle. Most of Mivart's book studies the regularities of embryology and comparative anatomy to learn which kinds of complex changes might be possible as expressions and elaborations of developmental programs already present in ancestors. He advocates these changes as possible and eliminates others as fanciful.)

Darwin then faced his dilemma and developed the interestingly paradoxical resolution that has been orthodox ever since (but more poorly understood and appreciated than any other principle in evolutionary theory). If complexity precludes sudden origin, and the dilemma of incipient stages forbids gradual development in functional continuity, then how can we ever get from here to there? Darwin replies that we must reject an unnecessary hidden assumption in this argument—the notion of functional continuity. We will all freely grant that no creature can fly with 2 percent of a wing, but why must the incipient stages be used for flight? If incipient stages originally performed a different function suited to their small size and minimal development, natural selection might superintend their increase as adaptations for this original role until they reached a stage suitable for their current use. In other words, the problem of incipient stages disappears because these early steps were not inadequate wings but well-adapted something-elses. This principle of *functional change in structural continuity* represents Darwin's elegant solution to the dilemma of incipient stages.

Darwin, in a *beau geste* of argument, even thanked Mivart for characterizing the dilemma so well—all the better to grant Darwin a chance to elaborate his solution. Darwin writes: "A good opportunity has thus been afforded [by Mivart] for enlarging a little on gradations of structure, often associated with changed functions—an important subject, which was not treated at sufficient length in the former editions of this work." Darwin, who rarely added intensifiers to his prose, felt so strongly about this principle of functional shift that he wrote: "In considering transitions of organs, it is so important to bear in mind the probability of conversion from one function to another."

Darwin presented numerous examples in chapters 5 and 7 of the final edition of the *Origin of Species*. He discussed organs that perform two functions, one primary, the other subsidiary, then relinquish the main use and elaborate the formerly inconspicuous operation. He then examined the flip side of this phenomenon—functions performed by two separate organs (fishes breathing with both lungs and gills). He argues that one organ may assume the entire function, leaving the other free for evolution to some other role (lungs for conversion to air bladders, for example, with respiration maintained entirely by gills). He does not, of course, neglect the classic example of wings, arguing that insects evolved their organs of flight from tracheae (or breathing organs—a minority theory today, but not without supporters). He writes: "It is therefore highly probable that in this great class organs which once served for respiration have been actually converted into organs of flight."

Darwin's critical theory of functional shift, usually (and most unfortunately) called the principle of "preadaptation,"* has been with us for a century. I believe that this principle has made so little headway, not primarily because it is paradoxical and difficult, but mainly because we have so little firm, direct evidence for such functional shifts. Our technical literature contains many facile verbal arguments—little more than plausible "just-so" stories. The fossil record also presents some excellent examples of sequential development through intermediary stages that could not work as modern organs do—but we lack a rigorous mechanical analysis function at the various stages.

Let us return, as we must, to the clas case of wings. *Archaeopteryx*, the fi bird, is as pretty an intermediate as leontology could ever hope to find— complex mélange of reptilian and avi features. Scientists are still arguing abo whether or not it could fly—if so, worked like the Wrights' biplane to a mo ern eagle's Concorde. But what did the discovered ancestors of *Archaeopteryx* with wing rudiments that surely could fly? Evolutionists have been invoking D win's principle of functional shift for mo than 100 years, and the list of proposals long. Protowings have been reconstruct as stabilizers, sexual attractors, or inse catchers. But the most popular hypothe identifies thermoregulation as the origi function of incipient stages that la evolved into feathered wings. Feathers modified reptilian scales, and they wo very well as insulating devices. Moreov if birds evolved from dinosaurs (as m paleontologists now believe), they ar from a lineage particularly subject problems with temperature control. *chaeopteryx* is smaller than any dinos and probably arose from the tiniest of nosaur lineages. Small animals, as a con quence of high ratios of surface area volume, lose heat rapidly and may requ supplementary devices for thermoregu tion. Most dinosaurs could probably ke warm enough just by being large. Surf area (length × length, or length squar increases more slowly than volume (leng × length × length, or length cubed) as jects grow. Since animals generate h over their volumes and lose it throu their surfaces, small animals (with th relatively large surface areas) have m trouble keeping warm.

There I go again—doing what I j criticized. I have presented a plausi

*This dreadful name has made a difficult principle even harder to grasp and understand. Preadaptation seems to imply that the protowing, while doing something else in its incipient stages, knew where it was going—predestined for a later conversion to flight. Textbooks usually introduce the word and then quickly disclaim any odor of foreordination. (But a name is obviously ill-chosen if it cannot be used without denying its literal meaning.) Of course, by "preadaptation" we only mean that some structures are fortuitously suited to other roles if elaborated, not that they arise with a different, future use in view—now there I go with the standard disclaimer. As another important limitation, preadaptation does not cover the important class of features that arise without functions (as developmental consequences of other primary adaptatio for example) but remain available for la co-optation. I suspect, for example, t many important functions of the hun brain are co-opted consequences of build such a large computer for a limited se adaptive uses. For these reasons, Elizab Vrba and I have proposed that the rest tive and confusing word preadaptation dropped in favor of the more inclusive te exaptation—for any organ not evolved der natural selection for its current use— ther because it performed a different fu tion in ancestors (classical preadaptati or because it represented a nonfunctio part available for later co-optation. See technical article, "Exaptation: A Miss Term in the Science of Form," Paleob ogy, vol. 8, 1981).

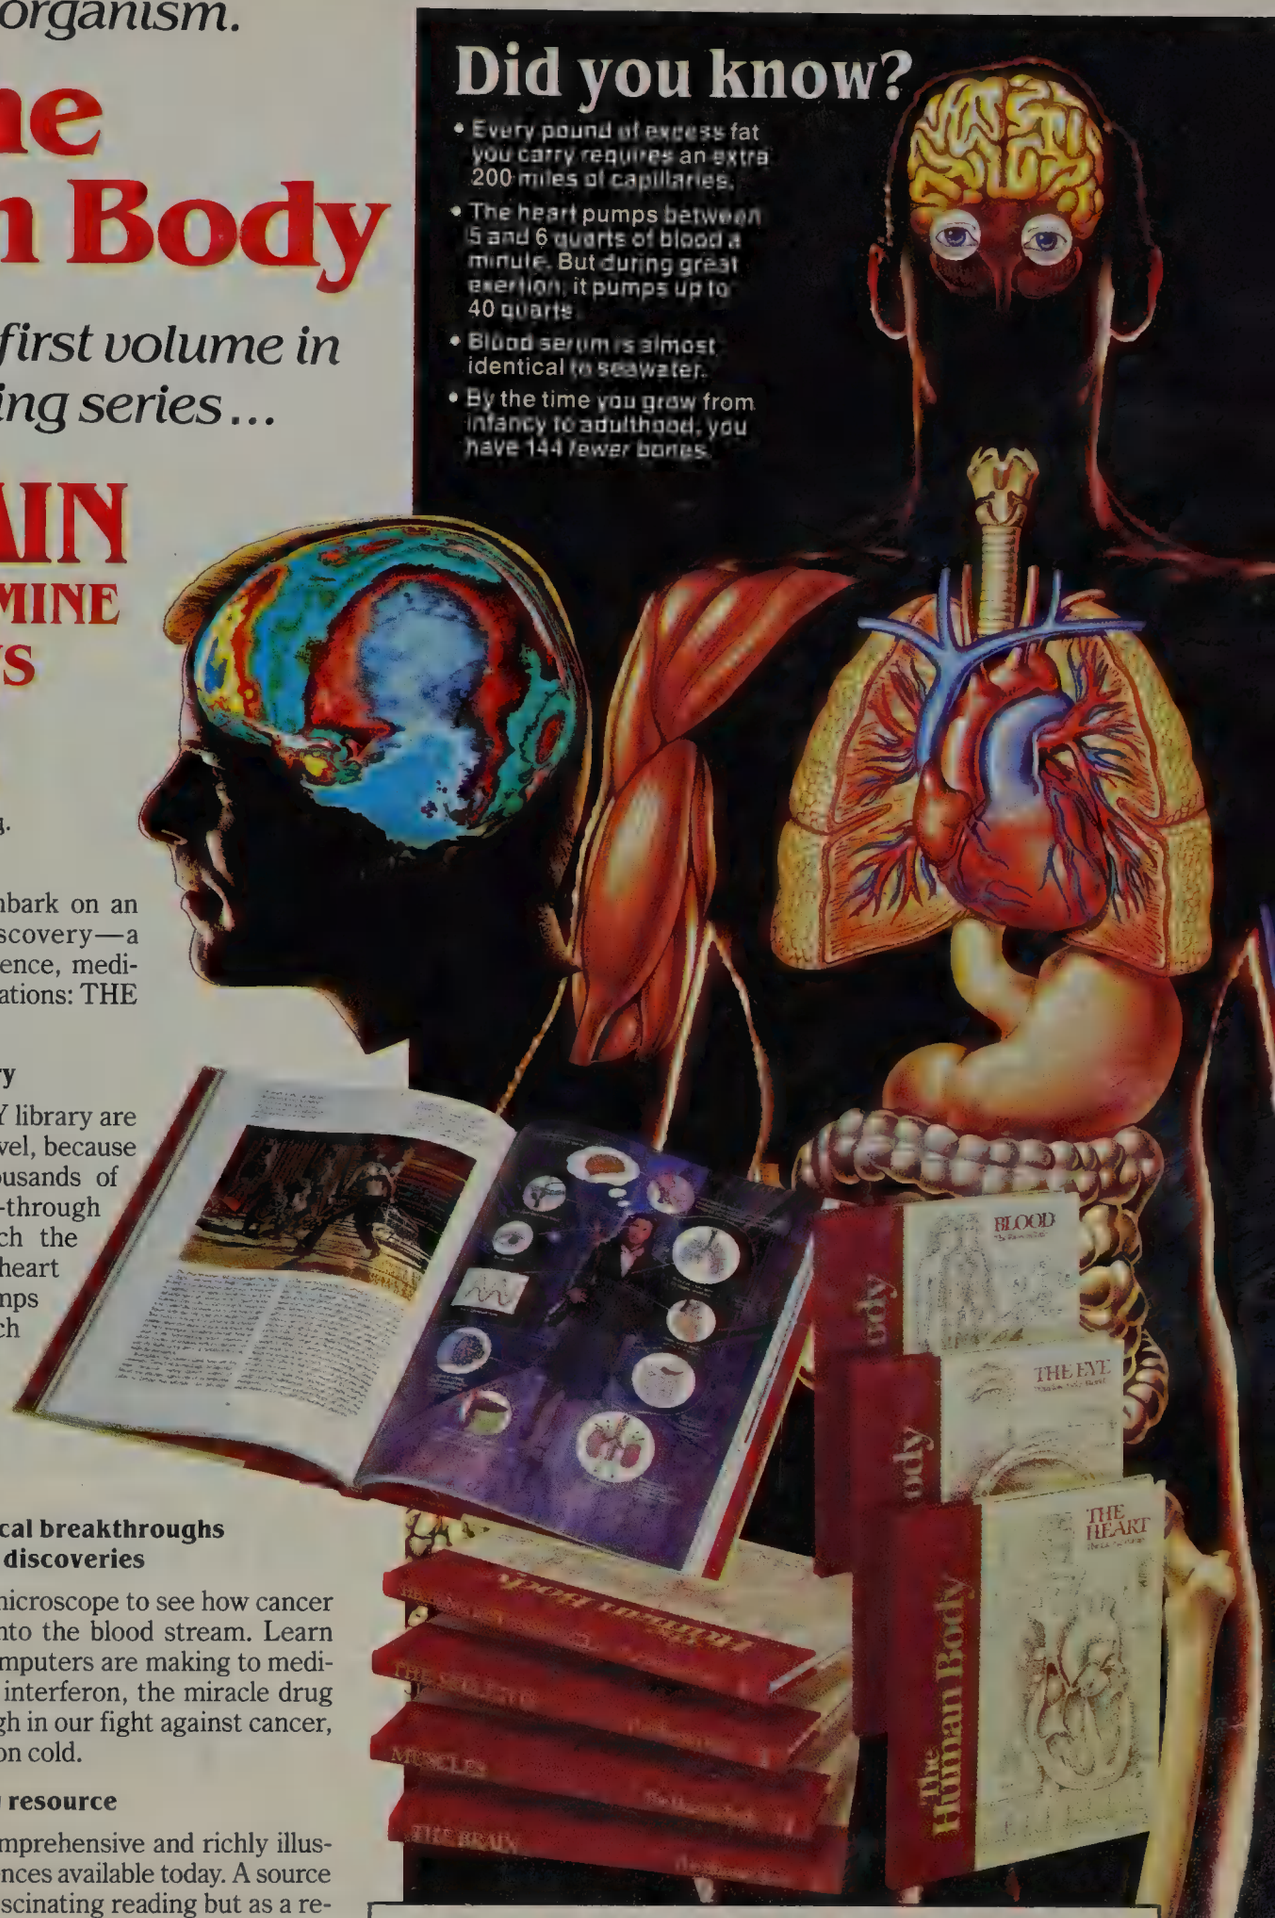
Did you know?

- Every pound of excess fat you carry requires an extra 200 miles of capillaries.
- The heart pumps between 5 and 6 quarts of blood a minute. But during great exertion, it pumps up to 40 quarts.
- Blood serum is almost identical to seawater.
- By the time you grow from infancy to adulthood, you have 144 fewer bones.



Act now and receive a digital thermometer FREE

- Electronic digital thermometer safe for adults and children.
- Quick and accurate body temperature readings in only 60 seconds. Over 1,000 hours of battery life.
- Buzzer sounds when temperature level has been reached.

On taking leave of Germany... and his teammates.

His tour of duty was over. This was his final good-bye. He remembered all the good times, the joking and that special closeness that comes from sharing not only victory, but defeat.

As he shook hands with Willi, Rolf, Dieter and the others, he realized they had become brothers.

And that was something he'd never forget.

Call West Germany. Ten minutes can average just 79¢ a minute.*

Saying good-bye is never easy—but saying hello is, with AT&T. A ten-minute phone call to West Germany on AT&T can average as little as 79¢ a minute.

Just dial the call yourself any night from 6 pm until 7 am.

If you don't have International Dialing in your area, you'll still get the same low rate as long as special operator assistance is not required.

AT&T International Long Distance Service.

ry about thermoregulation as the origi- function of organs that later evolved o wings—but where's the chicken, or otochicken. Science is tested evidence, t tall tales. This lamentable mode has en traditionally used to illustrate Dar- n's principle of functional shift only *ute de mieux*—because we didn't have e goods so ardently desired. At least un- last month, when my colleagues Joel G. ngsolver and M.A.R. Koehl published e first hard evidence to support a shift m thermoregulation to flight as a sce- rio for the evolution of wings. They died insects, not birds—but the same gument has long been favored for na- e's smaller and far more abundant ngs (see their article, "Aerodynamics, ermoregulation, and the Evolution of sect Wings: Differential Scaling and olutionary Change," in *Evolution*, vol. , 1985, pp. 488–504).

In preparing this essay, I spent several ys reading the classical literature on the lution of insect flight—and emerged h a deeper understanding of just how ficult Darwin's principle of functional ft can be, even for professionals. Most the literature hasn't even reached the t base of applying functional shift in first place, not to mention the later sta- ns of substituting direct evidence for bal speculation. Most reconstructions still trying to explain the incipient ges of insect wings as somehow in- ved in airborne performance from the rt—not for flapping flight, of course, t still for some aspect of motion aloft her than, as Darwin's principle would ggest, for some quite different function. To appreciate the dilemma of such a po- on (so well grasped by Mivart more n 100 years ago), consider just one re- nt study (probably the best and most dely cited) and the logical quandaries t a claim of functional continuity en- ls. In 1964, J.W. Flower (in the *Journal Insect Physiology*) presented aerody- mic arguments for wings evolved from iest first to elaborate last in the interest airborne motion. Flower argues, sup- ting an orthodox view, that wings lved from tiny outgrowths of the body d for gliding prior to elaboration for tained flight. But Flower recognizes t these incipient structures must them- ves evolve from antecedents too small function as gliding planes. What could se very first, slight outgrowths of the dy be for? Ignoring Darwin's principle functional shift, Flower searches for an odynamic meaning even at this very set. He tries to test two suggestions: H. Hinton's argument that initial out- wths served for "attitude control," per- mitting a falling insect to land in a suitable position for quick escape from predators; and a proposal of the great British entomologist Sir Vincent Wigglesworth (wonderful name for an insect man, I always thought) that such first stages might act as stabilizing or controlling devices during takeoff in small, passively aerial insects.

Flower proceeded by performing aerodynamic calculations on consequences of incipient wings to simple body shapes when dropped—and he quickly argued himself into an inextricable logical corner. He found, first of all, that tiny outgrowths might help, as Wigglesworth, Hinton, and others had suggested. But the argument foundered on another observation: the same advantages could be far more easily and effectively gained by another, readily available alternative route—evolution to small size (where increased surface/volume ratios retard falling and enhance the probability of takeoff). Flower then realized that he would have to specify a reasonably large body size for incipient wings to have any aerodynamic effect. But he then encountered another problem: at such sizes, legs work just as well as, if not better than, protowings for any suggested aerodynamic function. Flower admitted:

> The first conclusion to be drawn from these calculations is that the selective pressure in small insects is towards smaller insects, which would have no reason to evolve wings.

I would have stopped and searched elsewhere (in Darwin's principle of functional shift) at this point, but Flower bravely continued along an improbable path:

> The main conclusions, however, are that attitude control of insects would be by the use of legs or by very small changes in body shape.

As a general rule in science, one should examine basic premises when arguments founder. But Flower never considered an alternative to his assumption of functional continuity based upon some aspect of aerial locomotion. He concluded:

> At first they [protowings] would affect attitude; later they could increase to a larger size and act as a true wing, providing lift in their own right. Eventually they could move, giving the insect greater maneuverability during descent, and finally they could "flap," achieving sustained flight.

As an alternative to such speculative reconstructions that work, in their own terms, only by uncomfortable special pleading, may I suggest Darwin's old principle of functional shift (preadaptation—ugh—for something else).

The physiological literature contains voluminous testimony to the thermody-

A HISTORIC FIRST

1985 ▫ CANADA'S FIRST FEDERA

ROBERT

Print Size 12″ x 14″

Mallard Pair — Early Winter

© 1985 Robert Bateman

Image Size 6½″ x

A Limited Edition Art Print ▫ Signed and Numbered

Canada's First Federal Conservation Stamp and Print

You are invited to acquire this historic first issue conservation stamp and print initiated by Wildlife Habitat Canada (a non-profit organization) for the benefit of conservation projects. Beginning in 1985, migratory game bird hunters in Canada are required to affix this $4.00 stamp to their hunting permit.

For over 50 years, starting in 1934, hunters in the United States have been required to purchase the Federal Duck Stamp. And with this a great collecting tradition began. Stamps and limited edition prints of the designs have become some of the most collectible and prized items in America today.

Now you have the opportunity to acquire Canada's First Federal Conservation Stamp and Print. Discerning collectors know that first issues are invariably the most sought after and valuable in a series. Not only can you become part of a collecting first, but in addition the full $4.00 price of the stamp and a portion of the revenues from print sales will go to Wildlife Habitat Canada help further conservation efforts that are vital to the en continent.

Finest Quality Art Print

Mallard Pair — Early Winter will be published on the fi imported paper and printed in the same colors and hues to ma the original. It will be a vibrant, beautiful work reflecting Ba man's matchless talents. It will be protected by a special fol with the artist's biography and text about the painting enclose

Limited Edition

In the tradition of the finest and most sought-after art prin *Mallard Pair — Early Winter* will be issued for a limited time on and the total edition will be permanently limited to the ex number of valid reservations entered by January 31, 1986.

Signed by the Artist

As with truly fine art prints, *Mallard Pair — Early Winter* numbered print which will be personally pencil signed by

ONSERVATION STAMP and PRINT Original painted by

BATEMAN

Honored By The Government Of Canada

One Of Canada's Great Living Artists

North America's Most Sought-After Painter Of The Natural World

ert Bateman:

Bateman's meteoric rise to international eminence in the world of art is built on a solid foundation of education in art and natural science at the University of Toronto. Teaching in Africa, worldwide travel, sketching and study contributed to a developed style of Realsim which has captivated collectors on four continents. Bateman's own unique style cannot be imitated. His compositions are unique, and his concepts are always fresh, never repeated.

His works have become renowned for their dramatic compositions, remarkable realism and powerful immediacy, winning him a huge and loyal international following.

Almost always, when a new Bateman limited edition print is issued, it is sold out immediately. This leaves many collectors disappointed, but anticipating a chance to acquire his next issue.

Knowledgeable art dealers are predicting that *Mallard Pair — Early Winter* will be Bateman's most highly collected limited edition print...creating an even larger following of collectors.

Shown above is the stamp and print framed as you might display it in your home.

could paint like another artist of the natural world, it would be Robert Bateman."

Roger Tory Peterson
America's most honored artist/naturalist

obert Bateman. Both print and stamp will be placed in ve folders and when received will be ready for framing isplay with pride in your home or office.

namic efficiency of modern insect wings: in presenting, for example, a large surface area to the sun for quick heating (see B. Heinrich, *Insect Thermoregulation*, Academic Press, New York, 1981). If wings can perform this subsidiary function now, why not suspect thermoregulation as a primary role at the outset? M.M. Douglas, for example (*Science*, 1981, vol. 211, pp. 84–86), showed that, in *Colias* butterflies, only the basal one-third of the wing operates in thermoregulation—an area approximately equal to the thoracic lobes (protowings) of fossil insects considered ancestral to modern forms.

Douglas then cut down some *Colias* wings to the actual size of these fossil ancestral lobes and found that insects so bedecked showed a 55 percent greater increase in body temperature than bodies deprived of wings entirely. These manufactured protowings measured 5 by 3 millimeters on a body 15 millimeters long. Finally, Douglas determined that no further thermoregulatory advantage could be gained by wings longer than 10 millimeters on a 15-millimeter body.

Kingsolver and Koehl performed a host of elaborate and elegant experiments to support a thermoregulatory origin of insect protowings. As with so many exa ples of excellent science producing cl and interesting outcomes, the results c be summarized briefly and cleanly.

Kingsolver and Koehl begin by tabul ing all the aerodynamic hypotheses u ally presented in the literature as pur verbal speculations. They arrange th proposals of functional continuity (the planations that do not follow Darwin's lution of Mivart's dilemma) into three sic categories: protowings for glidi (aerofoils for steady-state motion), parachuting (slowing the rate of desc in a falling insect), and attitude stabil (helping an insect to land right side u They then transcended the purely verb tradition by developing aerodynan equations for exactly how protowi should help an insect under these three potheses of continuity in adaptation creasing the lift/drag ratio as the ma boost to gliding, increasing drag to sl the descent rate in parachuting, meas ing the moment about the body axis p duced by wings for the hypothesis of a tude stability).

They then constructed insect models wire, epoxy, and other appropriate mat als to match the sizes and body shapes flying and nonflying forms among ea insect fossils. To these models, they tached wings (made of copper wire encl ing thin, plastic membranes) of vari lengths and measured the actual aero namic effects for properties predicted various hypotheses of functional conti ity. The results of many experiments wind tunnels are consistent and con nant: aerodynamic benefits begin wings above a certain size, and they crease as wings get larger. But at the sm sizes of insect protowings, aerodynan advantages are absent or insignificant a do not increase with growing wing leng These results are independent of bo shape, wind velocity, presence or pla ment of legs, and mounting position wings. In other words, large wings w well and larger wings work better—l small wings (at the undoubted sizes Mivart's troubling incipient stages) p vide no aerodynamic edge.

Kingsolver and Koehl then tested th models for thermoregulatory effects, c structing wings from two materials w different thermal conductivities (c struction paper and aluminum foil) a measuring the increased temperature bodies supplied with wings of vari lengths versus wingless models. Th achieved results symmetrically oppo to the aerodynamic experiments. For th moregulation, wings work well at smallest sizes, with benefits increasing

ıe wing grows. However, beyond a mea-
ured length, further increase of the wing
ɔnfers no additional effect. Kingsolver
ıd Koehl conclude:

t any body size, there is a relative wing
ngth above which there is no additional
ermal effect, and below which there is no
gnificant aerodynamic effect.

he accompanying chart illustrates these
ɔmbined results. Note how the thermo-
gulatory effect of excess body tempera-
re due to wings (solid line) increases rap-
ly at small wing sizes but not at all above
ı intermediate wing length. Conversely,
e aerodynamic effect of lift/drag ratio
es not increase at all until intermediate
ng length and grows rapidly thereafter.
We could not hope for a more elegant
perimental confirmation of Darwin's so-
tion to Mivart's challenge. Kingsolver
d Koehl have actually measured the
nctional shift by showing that incipient
ngs aid thermoregulation but provide
aerodynamic benefit—while larger
ngs provide no further thermoregula-
ry oomph but initiate aerodynamic ad-
ntage and increase the benefits steadily
ereafter. The crucial intermediate wing
ngth, where thermoregulatory gain
ases and aerodynamic benefits begin,
presents a domain of functional shift, as aerodynamic advantages pick up the relay from waning thermoregulation to continue the evolutionary race to increasing wing size.

But what might push an insect across the transition? Why reach this crucial domain at all? If wings originally worked primarily for thermoregulation, why not just stop as the length of maximum benefit approached? Here, Kingsolver and Koehl present an interesting speculation based on another aspect of their data. They found that the domain of transition between thermal and aerial effects varied systematically with body size: the larger the body, the sooner the transition (in terms of relative wing length). For a 2-centimeter body length, the transition occurred with wings 40 to 60 percent of body length; but a 10-centimeter body switches to aerodynamic advantage at only 10 percent of body length.

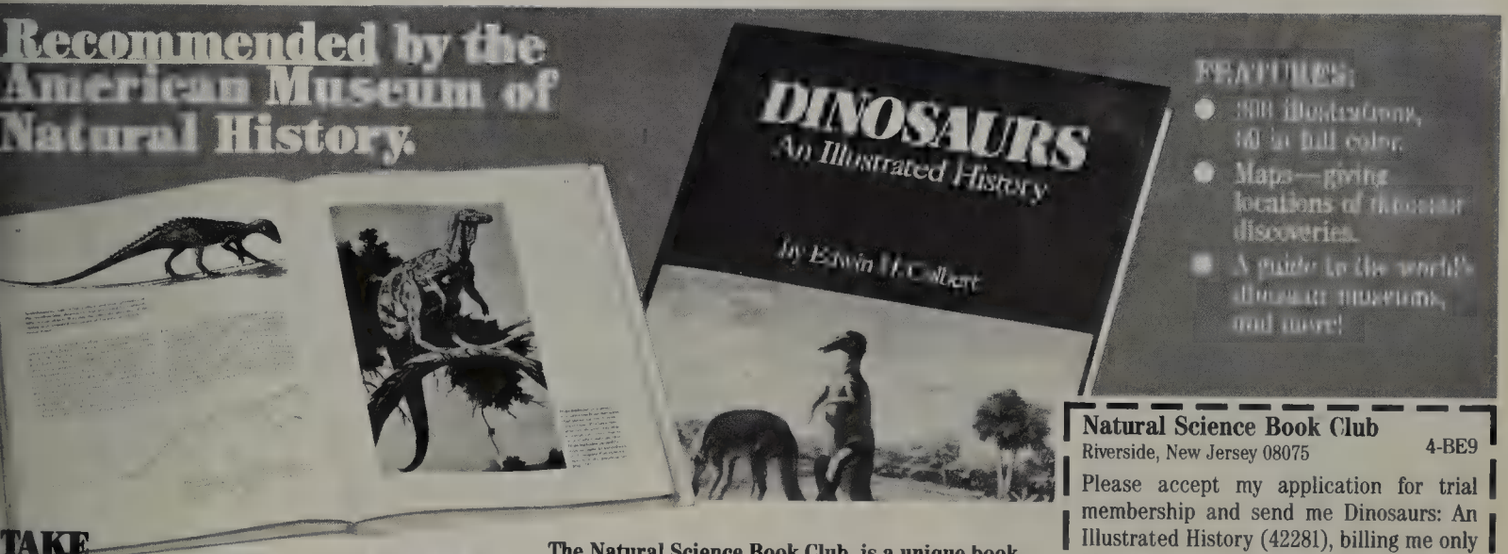
Now suppose that incipient ancestral wings worked primarily for thermoregulation and had reached a stable, optimum size for greatest benefit. Natural selection would not favor larger wings and a transition to the available domain of aerodynamic advantage. But if body size increased for other reasons, an insect might reach the realm of aerial effects simply by growing larger, without any accompanying change of body shape or relative wing length.

We often think, naively, that size itself should make no profound difference. Why should just more of the same have any major effect beyond simple accumulation? Surely, any major improvement or alteration must require an extensive and explicit redesign, a complex reordering of parts with invention of new items.

Nature does not always match our faulty intuitions. Truly complex objects often display the interesting and paradoxical property of major effect for apparently trifling input. Internal complexity can translate a simple quantitative change into a wondrous alteration of quality. Perhaps that greatest and most effective of all evolutionary inventions, the origin of human consciousness, required little more than an increase of brain power to a level where internal connections became rich and varied enough to force this seminal transition. The story may be more complex, but we have no proof that it must be.

Voltaire quipped that "God is always for the big battalions." More is not always better, but more can be very different.

Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.



TAKE
DINOSAURS 99¢
for only
when you join the Natural Science Book Club.

A $30.00 RETAIL VALUE

YOU SIMPLY AGREE TO
BUY ONE MORE BOOK
AT A HANDSOME DISCOUNT
WITHIN THE NEXT 12 MONTHS.

The most definitive and complete look at all that is known about dinosaurs is also a magnificently illustrated and annotated record of their natural history. Paleontologist Edwin Colbert explores their variety, describes the world they lived in, recounts the story of their unearthing just over 150 years ago, along with a unique glossary of names and terms, and other little known facts about their mystery. Were they hot- or cold-blooded? AND What made them disappear? Examine all these questions and more in *Dinosaurs: An Illustrated History.* Publisher's Price: $30.00.

The Natural Science Book Club is a unique book club devoted to bringing you exciting, refreshingly different books on all areas of the natural sciences. From the life story of early man to the death of the solar system... all the wonders of the natural world are revealed to members of the Natural Science Book Club.

MEMBERSHIP BENEFITS • In addition to getting Dinosaurs: An Illustrated History for only 99¢ when you join, you keep saving substantially on the books you buy. Also, you will immediately become eligible to participate in our Bonus Book Plan, with savings up to 70% off the publishers' prices. At 3-4 week intervals (16 times per year) you will receive the Book Club News, describing the Main Selection and Alternate Selections, together with a dated reply card. If you want the Main Selection, do nothing and it will be sent to you automatically. If you prefer another selection, or no book at all, simply indicate your choice on the card, and return it by the date specified. You will have at least 10 days to decide. If, because of late mail delivery of the News, you should receive a book you do not want, we guarantee return postage.

Natural Science Book Club
Riverside, New Jersey 08075 4-BE9

Natural History 10/85

Fossil Ancestors of Burma

To document the origin of the higher primates, paleoanthropologists have retraced the steps of a 1923 expedition

by Russell L. Ciochon

"On the road to Mandalay,/ Where the flyin' fishes play,/ An' the dawn comes up like thunder outer China 'crost the Bay!" So wrote Kipling at the turn of the century of the wonders and enchantment of Burma and its city of Mandalay. Today, as enchanting as ever, the road to Mandalay beckons to paleontologists because Burma is the only place in the world that has yielded fossil evidence of an important link in the primate order. There are two groups of primates on the earth today. The higher primates—monkeys, apes, and humans—are the most familiar. They are sometimes called the Anthropoidea, or humanlike primates. The lower primates—the lemurs, lorises, and tarsiers—make up the second group. These primitive primates, often called Prosimii, or pre-apes, were the first to evolve and were the forerunners of all later forms. However, fossils showing the beginning of the evolutionary branch leading from prosimians to anthropoids have been hard to come by.

An early discoverer of the "Burmese link" that demonstrates this transition was the legendary fossil collector Barnum Brown, a paleontologist at the American Museum of Natural History. In the spring of 1923, Brown and his wife, Lilian, arrived in Rangoon, the capital of Burma. They journeyed by river steamer up the broad, muddy Irrawaddy to the port of Pakokku. From there they mounted a miniexpedition to the little-explored Ponnyadaung (or Pondaung, as Brown spelled it) Hills, located deep in the teak-bamboo forest of Upper Burma. Outfitted with four bullocks, two small, mat-covered carts, and a pair of sway-backed saddle horses, they rode in search of the varicolored sandstones of the Pondaung Formation, rock deposits that had been discovered earlier in the century by British economic geologists. In the words of Lilian Brown, they were "rainbow-ch ing"—following the sedimentary roc shaded yellow, gray, red, purple, a green, seeking a prehistoric pot of gol

When Brown arrived in Burma, vir ally nothing was known about the ea prehistoric life of southern Asia. The p vailing scientific opinion was that A was the mother of all continents, the ce ter of origin for much of the earth's li Brown had been sent by the Americ Museum to collect late Eocene (40- to million-year-old) fossils in support of t "Garden of Eden" theory. He specifica sought to collect large skulls and skelet of extinct animals that could be exhibit at the American Museum.

For two months, Brown's small bullo cart caravan creaked along the dirt trac the only roads in this remote part Burma. Because the resident comm sioner of Burma had provided a letter introduction to all village headmen alo

Lilian Brown, A

In 1923, Barnum Brown (mounted) collected fossils in Burma's Ponnyadaung Hills. This photograph (here tinted) was printe Natural History *in 1925, with a caption noting that the servant Mari (in the cart) died of malaria contracted on the journey.*

5,000,000 have diabetes and don't know it...

You could be one

It's estimated that 5 million Americans have diabetes and don't know it. The early symptoms are vague and may seem minor. As a result, they are often ignored or not taken seriously enough. Yet, if undiagnosed, diabetes can lead to serious complications affecting various parts of the body, including eyes, heart, kidneys, brain or even life itself.

What are the symptoms of diabetes?

There may be none. Or there may be such simple things as an increase in skin infections or a slower healing of bruises and cuts. Also, be aware of excessive thirst or hunger, frequent need to urinate and extreme fatigue.

These symptoms do not necessarily occur all at once and they usually develop gradually. So it's easy to understand how they can be overlooked or considered part of the normal aging process.

It is important, therefore, to be alert to changes in your body and report them directly to your doctor. You have a greater chance of being diabetic if you are over 40, overweight or have a history of diabetes anywhere in the family.

What is diabetes?

Diabetes is a disorder in which the body cannot control the levels of sugar in the blood. Normally the hormone, insulin, regulates the blood sugar level. But if your body does not produce or effectively use its insulin, diabetes results.

Treatment of diabetes.

Diabetes usually can be successfully managed. Some diabetics need no more than weight reduction, the right foods and moderate exercise to bring blood sugar levels under control. And, if these changes are not enough, a simple oral medication is all that may be needed. Today, even those who need insulin can be better and more comfortably managed by their doctors than ever before.

The diagnosis is easy.

But only your doctor can make it. And remember, if you are over 40 and overweight, or have diabetes in your family, you should have regular blood and urine tests. Early diagnosis in adults can lead to better management and fewer problems later on.

Only your doctor can prescribe treatment.

Follow your doctor's advice about diet, exercise and medication. Also, be aware that you have a support system, which we call...

Partners in Healthcare:

You are the most important partner.

Only you can see your doctor for a proper medical checkup. And it's you who must decide to accept the guidance and counseling of your physician, pharmacist and other healthcare professionals. When medications are prescribed, only you can take them as directed.

Your doctor orders your tests and makes the diagnosis.

Your physician will advise you on your weight, your diet and your exercise, and also decide if you require medication. He will help you monitor your progress.

All those who discover, develop and distribute medicines complete the partnership.

Pfizer's ongoing research brings you essential medicines for a wide range of diseases. Through development of these and many other medications, along with providing important healthcare information, we are fulfilling our responsibility as one of your partners in healthcare.

For additional information on diabetes, please contact your local American Diabetes Association affiliate, or call 1-800-227-6776.

For reprints of this Healthcare Series, please write: Pfizer Pharmaceuticals, Post Office Box 3852D, Grand Central Station, New York, NY 10163

Joe LeMor

the route, Brown was able to camp in villages that were nearest to exposures of the fossil-bearing Pondaung sandstones. One such stop brought him to the outskirts of Mogaung village, where he set up camp with Lilian and their two servants, Mari and Dos. Early each morning Brown would ride off in search of new fossil sites. One day, a short distance northwest of the village, he came upon a locality where he saw a number of small bones and teeth eroding out of the rock. Here he picked up part of a jaw with three teeth—a piece about the size of a fifty cent coin—that belonged to a medium-size primate.

Barnum Brown probably did not realize that what he had discovered was an early higher primate. But Edwin Colbert, Brown's colleague at the American Museum, did, and in 1937 he named the jaw *Amphipithecus mogaungensis* (near-ape of Mogaung). *Amphipithecus* joined the ranks of another Burmese fossil primate, discovered in 1913 by paleontologist G.D.P. Cotter. Cotter had explored the southern exposures of Burma's Ponnyadaung Hills while working for Britain's Geological Survey of India. A description of this specimen (a piece of upper jaw and two pieces of lower jaw) was published in 1927 by Guy Pilgrim, who named it *Pondaungia cotteri*. Pilgrim thought it could be an Eocene higher primate, but the fragments were too scrappy for precise identification. With Colbert's more confident description of *Amphipithecus* in 1937, the late Eocene beds of the Ponnyadaung Hills became known as the source of the earliest record of the Anthropoidea.

Anthropologists debated the evolutionary affinities of *Amphipithecus* and *Pondaungia* for the next four decades. Were they really the world's earliest higher primates or were they prosimians with a few independently evolved anthropoidl features? Was Asia even the place to lo for the origin of the higher primat More fossil evidence was needed, but one was able to work in the Ponnyadau Hills during the years embracing the J anese invasion, World War II, Burm achievement of independence, and emergence of nationalistic policies t followed.

I first visited Burma in 1975, to disc the possibility of a joint U.S.-Burm paleoanthropological research proje With U.S. involvement in the Vietn War drawing to a close, my proposals on receptive ears. After discussing pl with geologists at the Mandalay Arts a Sciences University, I submitted a let to the Ministry of Foreign Affairs. The ply stated that the Ministry had objection to a planned paleontologi visit." On my return to the United Stat teamed up with Donald E. Savage, a s soned paleontologist, and in March 19 having obtained the necessary fund and entry visas, we set off on a two-mo research tour of Burma.

Upon arrival in Rangoon, however, were only given permission to prospect fossils along the Irrawaddy River dra age, where the sediments date from Pleistocene epoch (the last 2 million ye of earth history). Ministry officials clared that the area around the more cient Ponnyadaung Hills was so dang ous that we would need a police esc which could not be provided at the ti Swallowing our disappointment, we f north to Mandalay, where we were met U Ba Maw and U Thaw Tint, our leagues at Mandalay University, al with a geology student who was to be field coordinator, Tin Maung Oo (v likes to be called "Tin").

Membership/ Subscription Problems?

We Want To Help!

Sometimes, all you need is information. Here are some helpful facts:

Orders – Changes of Address

It takes us from 6 to 8 weeks to process an order, a payment, a renewal, a change of address, or any kind of adjustment to your membership/subscription. So count on about 6 to 8 weeks from the time you place an order until the time you get your first magazine. If you send us a change of address, count on the same 6 to 8 weeks before the magazine is delivered to your new address. (And remember, when registering a change of address, be sure to give us your old address as well as your new one.)

Bills – Renewals

If you send us a payment, you may receive another bill, or even two, before the payment is recorded, and the computer is told to stop sending you bills. Don't be concerned. Just ignore the extra bill. If you send us a renewal, you may receive one or even two more renewal notices before the renewal is recorded, and the computer is told to stop sending you renewal notices. Please respond to only one notice and ignore the extras. And remember, if you wait until just before your membership/subscription expires to renew, you may miss one or even two issues before the renewal is recorded. Renew early to avoid this possibility!

New Offers

If you are already a member/subscriber, and you receive a new member/subscriber's introductory offer from us, it's because we have used another reputable organization's mailing list. We aren't perfect. We try to screen out our own subscribers' names from these lists to save money, but sometimes it isn't possible. If there is even the slightest difference in the name and/or address (for instance, Mary Roberts and M. Roberts, or Mrs. Roberts, or 12 Oak Road and 12 Oak) the computer can't tell that it's the same name. So we'd appreciate it if you'ld simply give that introductory offer to a friend you think might enjoy Natural History.

Missed Issues

If you miss one or more issues, it may mean that your name and address have been entered incorrectly on our computer, or that we haven't received your payment, or renewal instructions. Or the Postal Service may have failed to deliver the copy that we sent. If you miss one or more issues, please contact us. With your help, we'll rectify whatever mistake was made.

Problem Correspondence

If you have written to us about a problem and not received an answer, please don't be upset. We may have been able to solve the problem without further correspondence. If the problem persists, though, don't hesitate to contact us directly. Remember to give us your complete return address as it appears on your magazine label, or we won't be able to write back.

For help or information on your membership/subscription, write:

Own America's First Silver Dollar

Original 200 year old coins that were legal tender of our 13 colonies

Minted from 1772-1821, these silver dollars were the most popular coins of our 13 colonies.

September, 1985, MONTPELIER, VERMONT — International Coins & Currency, Inc. a national distributor of numismatic coins, is offering for sale a limited number of original 200 year old coins — among the first large silver dollars minted in the Americas. These magnificent silver coins once circulated in our original 13 colonies and the early USA. Because of their high silver content and popularity, Thomas Jefferson recommended that they become official legal tender of the United States of America.

Minted from 1772-1821, these silver dollars were the most popular coins of our 13 colonies and were used as legal tender in the USA up until 1857. As collectors and investors turn to American coin classics, these scarce silver dollars are becoming increasingly sought-after and desirable.

Struck at the Americas' oldest mint in Mexico City and denominated 8 Reales, these silver dollars were the forerunners of the first U.S. silver dollar minted in 1794 — and served as the most favored trade coin in the world. Yet huge silver melts and the fact that relatively few were saved from destruction make these coins "sleeping" classics. Each silver dollar is a big 39.5 mm in diameter, contains 27.07 grams of .903 pure silver, and each comes with a Certificate of Authenticity attesting to its fine quality and genuine status. This guarantee never runs out. Because the supply was originally discovered in the Far East, genuine "Chinese merchant markings" are often visible and serve to authenticate the coins.

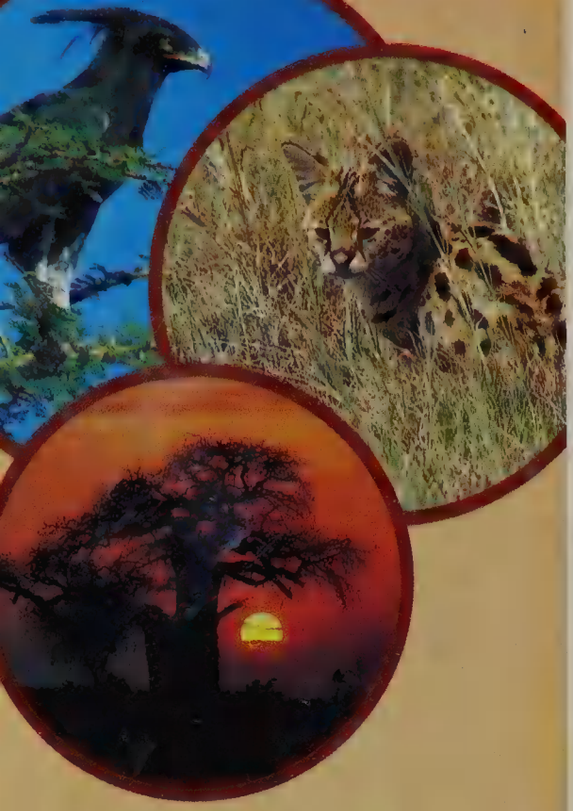
Because of the age and historical significance of these coins, you might expect to pay up to several hundred dollars for one. But while supplies last, they are available on a first-come, first-served basis for $75 each — and you can save up to $75 by buying more than one. International Coins & Currency, Inc. is offering for sale a limited number of these coins to collectors and investors at:

1 coin $75; 2 coins $150;
3 coins $215 (save $10);
5 coins $345 (save $30);
and 10 coins $675 (save $75).

There is a strict limit of 10 coins per customer. Your 100% satisfaction is guaranteed — you may return your order for a prompt no-questions-asked refund within 15 days (less postage and insurance of course).

To order your coins by credit card, call toll free at 1-800-451-4463, 24 hours a day, 7 days a week (including Sundays).

If you prefer, send check or money order in full amount to: International Coins & Currency, Inc. Dept. 833, 11 East State, P.O. Box 218, Montpelier, Vermont 05602. Add $3.75 for 1 coin or $5.00 for more than 1 coin to cover postage and insurance. Special presentation cases for individual coins are also available at $2.50 each. Mr. Douglas Schneible, ICC's Numismatic Director is Life Member No. 1305 in the American Numismatic Association. All coins are available for prompt delivery.



AFRICA

Tanzania–Kenya

The romantic idea of an East African safari has been fixed in your mind since you were a child, but nothing can compare to firsthand experience. From Tanzania's beautiful Ngorongoro Crater and endless Serengeti plains to the awesome escarpments and flamingo-covered soda lakes of the Great Rift Valley in Kenya, these expeditions represent a dream come true!

KLM

For the next six weeks we explored a 300-mile section of the Irrawaddy River, collecting fossils along its banks and terraces. This fieldwork was rewarding, but we yearned to visit the Ponnyadaung Hills, a mere 200 miles to the west. To impress upon our Burmese colleagues how eager we were for information about the 40-million-year-old fossil beds, we left our copies of Barnum Brown's field maps and publications with them. They promised to attempt a reconnaissance of the region in the late fall dry season.

Savage and I returned home and awaited further word on our research proposal to the Burmese government and on results from our Burmese collaborators' visit to the Ponnyadaung Hills. We had heard nothing for almost a year when suddenly a small package arrived from Mandalay. It contained plaster casts of jaws and teeth of several Eocene mammals, one of which was a nicely preserved jaw of *Pondaungia*. U Ba Maw and U Thaw Tint had not only found Brown's localities; they had also succeeded in recovering a new fossil primate. An accompanying letter stated that they had found many more fossil mammal specimens, several of which they thought could also be primates. They encouraged us to return to Burma as soon as possible to visit the localities and to work with them on publication of the finds. In December 1978, arrangements were made, and we departed once again for Burma.

On our approach into Mingaladon Airport in Rangoon we were asked to set our watches back thirty minutes in accordance with Burma Standard Time. The British businessman sitting next to me intoned, "Set your watch back thirty minutes and turn time back thirty years." Indeed, little has changed in Burma since its independence in 1948. But our minds were set on a much longer time frame, for

This drawing of Amphipithecus *is based on fossil evidence and an interpretation of the order of evolution of anatomical features found in living higher primates.*

Russell L. Ciochon

Our knowledge of Amphipithecus *comes from fragments of two separate jaws. One portion (left) was found in 1923, another (shown overlapping) in 1977.*

we were hoping to turn time back 40 million years!

After several days of preliminaries, we made the short hop by air to Mandalay and prepared for our journey to the Ponnyadaung Hills. U Ba Maw and U Thaw Tint could not accompany us on this trip since they were in the middle of university exams, but they sent some of their students with us. Before dawn on December 20, our small caravan—two World War II–vintage jeeps loaded with camping and excavation equipment, four geology students, a cook, a mechanic, two drivers, Tin, Savage, and myself—left for the field.

To reach the Ponnyadaung Hills we had to cross the two great rivers of Burma. Crossing the Irrawaddy was a simple matter of driving over a steel-girder bridge, but at the Chindwin River our two jeeps had to be loaded onto a flatbed barge along with chickens, goats, bicycles, and a large number of other passengers. A small tug then towed us across the mile-wide river. After several more hours of driving we reached the Pale Township People's Council, where we checked in and picked up an escort of several armed policemen. Our Burmese colleagues had assured us that the only danger in the Ponnyadaung Hills was an unlikely encounter with a Bengal tiger, but for the sake of appearances, we decided to accept the offer of an escort.

On our five-hour climb from Pale into the Ponnyadaung Hills, the road deteriorated rapidly from a graded gravel track into a series of potholes and dust bowls interspersed by washboard. The open scrub brush and farmland near the Chindwin River quickly gave way to gently rolling forested hills. As we climbed still farther, the road became very steep, and the teak and bamboo forest surrounding us came alive with azure butterflies, screeching parakeets, and scampering red-orange jungle fowl. We encountered young Bu

This holiday season give the **distinctive gift** that is inexpensive and easy to give. **Natural History** is the perfect holiday gift that keeps giving all year long.

It's inexpensive—only $20 for your first gift
It saves you money—only $14 for each additional gift
It's easy—Use the postage paid cards in the magazine or call the toll-free number listed below.

Your gift recipient(s) will receive a valuable membership card that entitles him or her to all the benefits listed on the right. You'll be able to announce each gift with an attractive gift card we will send you as soon as we receive your order.

Give the gift of Natural History and membership in the American Museum today!

Your Gift brings all these Benefits:

- A one year subscription to Natural History (12 issues)
- Free admission to the American Museum of Natural History
- Access to the air-conditioned Members' Lounge
- Travel opportunities led by Museum scientists to all parts of the world
- Discounts on artwork, books, crafts, jewelry, and other gift items from our Museum shop
- Admission to special features and programs
- A valuable membership card
- Free ticket to our NatureMax Theatre

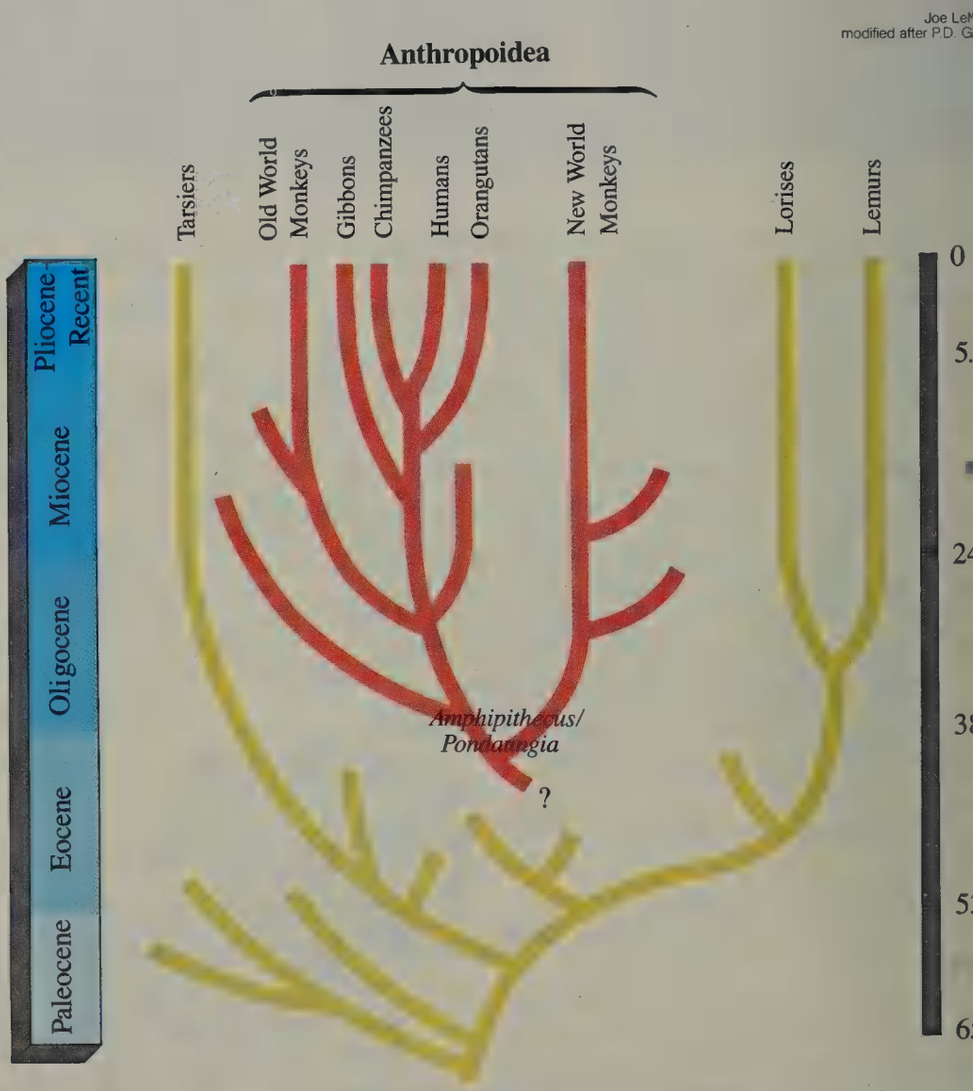
mese men driving oxcarts loaded down with teak logs, but not a single motorized vehicle. At the fifty-five-mile post the road became impassable for even a four-wheel-drive jeep. We transferred our supplies onto two oxcarts, each pulled by two grunting oxen, and began the eight-mile hike down an old cart road into Mogaung village. The oxcart wheels creaked and squeaked—but not as a result of neglect, I was told; rather, the local villagers never grease the wheels because they feel the noise keeps away evil spirits.

Late in the evening of our daylong trek we reached our destination—Mogaung, a village of some nine hundred people. Surrounding the village, which consists of small teak huts raised off the ground on poles, is a bamboo fence. Inside, banana, coconut, and toddy palm trees grow in abundance, and pigs and chickens roam freely. We were led to the hut of U Gyo, the village headman, where we were fed a traditional snack of bananas and green leaf tea. With Tin acting as translato Gyo greeted us graciously and sugge we use the new village schoolhouse base camp. It was rice-planting time, school was not in session. We were hausted, and after a quick meal of chi curry, everyone bedded down.

Early the next morning, with Bar Brown's field map in hand, we proce on foot northwest from Mogaung, thr flooded paddy fields, across s streams, and along well-worn paths ir forest. After we had walked about mile through the lush forest cover, rainbow-banded sediments of the daung Formation suddenly appeared. local villagers called these areas *chaung,* "places without vegetation." ing to the chemical properties of the ments, vegetation, especially fra young rice plants, is not able to gro them. In this case the villager's loss is paleontologist's gain.

Since Barnum Brown had left very



A family tree of the primates lists living groups at the top. The major fossil species some of which left no descendants, are represented vertically by the branching tree. The Anthropoidea, or higher primates, are shown in orange; the Prosimii, or lower primates, which comprise all other primates, form a less unified group (yellow). Some early prosimians, perhaps a group related to lemurs and lorises, gave rise to Anthropoidea. Amphipithecus *and* Pondaungia *are transitional forms that posses a number of anthropoid features but also retain a few prosimian characteristics.*

cise field notes, we had no trouble finding his localities, and we soon began to accumulate a treasure trove of fossils. The Burmese geology students also showed us the spot where the new primate jaw had been found. Over the next couple of days, Savage and I collected the remains of many extinct animals, including hippo- and piglike anthracotheres, rhinolike brontotheres, small deerlike artiodactyls, rodents, lizards, turtles, fishes, and crocodiles. From studies of this fauna and some associated plant remains, together with an understanding of the type of rocks in which they occur, we can reconstruct the paleoenvironment of this part of Burma in the late Eocene. The sediments were deposited by a medium-size river that drained seaward toward the Burmese Gulf, which in the past was located much farther north. Along the banks of this river, which was partially covered by a forest canopy, anthracotheres, brontotheres, and small artiodactyls came to drink. Turtles, crocodiles, and fish swam in the river. In the trees above, the ancestors of the higher primates romped.

On our second night in Mogaung village, the headman, U Gyo, honored us with a visit to "get better acquainted." As spiritual leader and chief administrator of Mogaung, U Gyo had considerable power, but being sixty-five years of age, he had learned to use his position wisely. He spoke of how Mogaung village had changed over the past half century ("actually, very little"). I then asked him when Mogaung had last been visited by Westerners, "people like ourselves." U Gyo thought a while and then began to recount the following story:

When I was a young boy of ten, I remember a white man and woman coming on horseback with several oxcarts of supplies. With the help of Mogaung villagers, they set camp only a few hundred yards from wh we are sitting. The man would ride off ea morning and return late in the evening w his horse packed with odd-shaped roc The woman, who wore pants but was str ingly beautiful, would stay in camp a play with a small dog, whose hair she w constantly combing.

We immediately realized that U Gyo w describing Barnum and Lilian Brown later showed him a photograph of Bro taken in Burma in 1923, and he confirm the identification.

After several more days of fossil hu ing around Mogaung village, we decid to hike to a locality Brown had discover some six miles to the northeast, near t village of Gyat. We found some excelle exposures near a large lotus pond, whi we could recognize from a photograph Brown published in *Natural History* 1925. Unfortunately, we were not able find any fossils. In the late afternoon trekked back to Mogaung, where our co was preparing a special holiday meal roast chicken and potatoes. It was Chri mas Eve. Savage and I rested and sippe clear, sweet alcoholic drink distilled fr the fruit of the toddy palm tree. As the s sank behind the mountains, the air b came chilled, bringing out the smell of t teakwood smoke and frying oil.

As darkness fell we heard a commoti in the distance. One of our police guar who had not returned with the field par burst into camp brandishing his weap proudly. He led a procession of village two of whom shouldered a rough-hew pole carrying a small deer. The deer w immediately butchered and some pa roasted that night. The following day proceeded to our next camp, at near Legan village. There, the deer meat p

Outcrops of the 40-million-year-old Pondaung Formation are bare of vegetation.

ded a magnificent Christmas Day feast
r our entire field party and all the village
ders.

After another week of fossil hunting, we
urneyed back to Mandalay, where more
xcitement was in store for us. At the
Iandalay Arts and Sciences University
e met with U Ba Maw and U Thaw Tint,
ho produced a box of small fossil jaws
ey had collected in the Ponnyadaung
ills. They weren't sure what the six
ieces were, but they had an idea they
ight be primates. Savage and I were al-
ost breathless as each jaw was removed
om the box. The first was a primate, the
iginal of the cast they had previously
nt us. Three of the others also proved to
e early anthropoids. U Ba Maw and U
haw Tint had tripled the early anthro-
id sample of Burma. Of the four pri-
ate jaws they had discovered, two were
ondaungia and one was *Amphipithecus*.
he fourth may represent a type of pri-
ate previously unknown to science. Our
rmese colleagues asked us to help them
blish these finds in Western journals.

After returning to the United States,
avage and I began to study the casts and
otographs of the new Ponnyadaung fos-
ls, making comparisons with Brown's
mphipithecus jaw and Cotter's *Pon-*
aungia specimens. Since several of the
w specimens are more complete than
e older fossils, the characteristics of the
o species are becoming clearer. Both
ssil forms exhibit a combination of lower
d higher primate features, with the lat-
r considerably more predominant, indi-
ting that they were at or across the evo-
tionary transition from prosimian to
thropoid.

Some of the lines of evidence that point
this conclusion can be illustrated by a
ok at *Amphipithecus*, the better known
the two species. For one thing, this gib-
n-size animal, probably weighing about
enty pounds, was relatively large in
mparison to most lower primates alive
the Eocene or even today. The lower
w is deep (top to bottom), both abso-
tely and in relation to the height of the
eth, and this depth extends the full
ngth of the jaw. In the lower primates,
e jaw is not as deep and lessens in height
ward the front. The *Amphipithecus* jaw
also very robust (thick). These jaw
aracteristics relate to the fact that the
ght and left halves of the lower jaw were
sed, unlike those of nearly all extinct
d living prosimians, whose jaws move
dependently as they chew. The fused
ws of anthropoids, which evolved for
ewing tougher foods, are strengthened
d reinforced to withstand the extra
esses that are placed on them during

Unlike other answering machines, the new Toshiba won't give you the silent treatment. It says nice things like "No message," or "Three messages. Monday 8:15 pm..." Our remote feature lets you play back, skip, repeat or even change messages from anywhere. Press a button, and Toshiba will always give you the time of day. Rand McNally Presents Mercury—
A World-Class Relief Globe

A globe is like an encyclopedia or Bible—no educated home is complete without it. Maps are all very well and good, but only the three-dimensionality of a globe can accurately represent the shape and proportions of our planet.

Now Rand McNally has designed the Mercury Relief Globe, a magnificently detailed, 18½"tall model of the world. And it's available for only $29.95! Never before has such a high-quality globe been sold at such a low price.

An Earthshaking Bargain at Only $29.95

The Mercury offers features you just won't find on a conventional globe. It's made of attractive, durable polystyrene and shows the earth's topography, elevations, vegetation patterns, ocean currents, international date line and more. The globe contains 2,351 place names, from the tallest peaks to the tiniest islands!

As if all that weren't enough, the Mercury GLOWS IN THE DARK, revealing national boundaries and country names printed in contrasting solid colors. And so, the globe can serve as a night light for your child while teaching him about geography at the same time!

The *Free* Globe Handbook
Gives You a World of Information

To ensure that you get the full enjoyment out of your Mercury, we're including a full-color handbook that tells how to use the globe and explains earth-space relationships, the planets, and more.

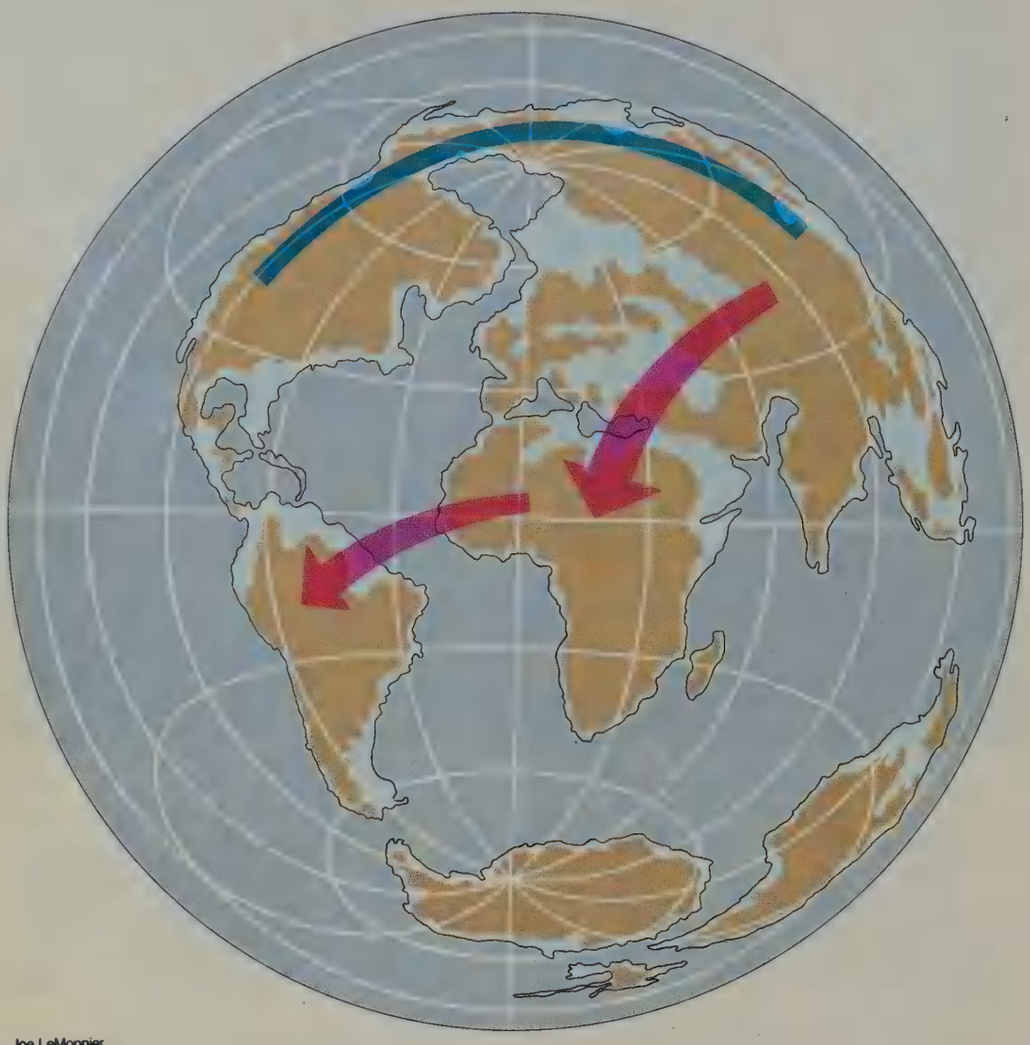
Migration of the Early Anthropoids



Joe LeMonnier

The relative positions of continents, oceans, and shallow seas 40 million years ago are reconstructed in a map of the earth's surface. Before higher primates (anthropoids) evolved, lower primates were present in Europe, Asia, North America, and probably Africa. The Burma fossil finds suggest that the higher primates arose from lower primates in Asia. Early forms probably then spread to Africa and, by way of volcanic islands, to South America (red arrows). Those in Africa subsequently gave rise to all the Old World monkeys, apes, and humans, while the New World monkeys evolved on their own in South America. Another possibility (indicated by the blue band) is that a population of early higher primates came to occupy parts of both Asia and North America, which were connected by a land bridge. When this connection was severed, the New World and Old World groups began to evolve independently, the New World group eventually migrating to South America. No one has discovered fossils of higher primates in North America to support this second hypothesis.

mastication. As in all anthropoids, the jaws of *Amphipithecus* are buttressed where they join by two horizontal, shelf-like thickenings of bone, called tori. (In contrast, the minority of Eocene lower primates that have fused jaws exhibit only one torus, suggesting they are unrelated to *Amphipithecus*.)

The cusps, or elevations, on the chewing surfaces of the teeth are relatively flat, a trend found in fruit eaters. Most prosimian teeth, instead, have a very crested cutting surface, useful for a diet of insects or leaves. In this respect, *Amphipithecus* resembles 30- to 35-million-year-old anthropoids found in Egypt's Fayum province (see "Dawn Ape of the Fayum," by Elwyn L. Simons, *Natural History*, May 1984). Another important consideration is the number of teeth in the jaw. Among primates in general, there is a long evolutionary trend toward reduction in the number of teeth. *Amphipithecus* has three premolars, a relatively primitive feature it shares with some prosimians and New World monkeys. Old World monkeys (as well as apes and humans) have two premolars. In this respect, *Amphipithecus* (or some closely allied species) is a suitable candidate as a forerunner of both the New World and Old World anthropoids—in other words, of all higher primates.

The original specimen of the *Amph pithecus* lower jaw contained the root the canine tooth, the root of the first pr molar, the second and third premolar and the first molar. Luckily, the new spe imen has helped complete the pictur since it contains the first and second m lars and part of the third. The squa shape of the second molar (viewed fro above) is significant, because this characteristic of anthropoids. In contras among the lower primates there is a na rowing toward the front of this tooth. Th newly discovered first molar has resolve a rather arcane controversy over the poss ble position of a rearward cusp known the hypoconulid. A nick in the origin specimen, where some believed this cus had broken off, was not in the positio characteristic of higher primates. As turns out, the new specimen shows there no hypoconulid cusp at all on the first an second molars. In this feature, *Amph pithecus* differs from all Old World a thropoids but resembles many Ne World monkeys.

The fossil finds from Burma sugge that the first higher primates evolved Asia some 40 to 45 million years ago an spread from there to the other parts of th world. This geographic spread could hav occurred by way of a number of route but I believe that the most likely sequenc was the following one. At the end of th Eocene, early anthropoids, the Ponny daung primates or their close relatives, m grated across Asia into Africa by crossin the narrow, swamplike Tethys Sea, whic then separated the two continents. Once Africa, these early higher primates contin ued to evolve, with some populations b coming ancestors of the 30- to 35-millio year-old Fayum primates of Egypt (an ultimately of all Old World monkey apes, and humans). Other populatio crossed the then-narrow equatorial Atla tic Ocean by island hopping along a seri of volcanic islands. In this way the reached South America and became th ancestors of the New World monkeys.

The increasing clarity with which Wes ern paleontologists are now able to vie these events in primate evolution is owe in large part to the discoveries made b our Burmese colleagues, who continue search for more fossil evidence. Althoug I have returned to Burma several tim since my memorable visit to Mogaung v lage, I have not been granted furth opportunity to visit the Ponnyadau Hills. While a field trip to southern Chi was arranged in 1983, and one to Vietna is planned for next year (both countri have related geological deposits), the roa to Mandalay still beckons.

NATURAL HISTORY DIARY & ADDRESS BOOK

Very rare natural history illustrations grace the *1986 Natural History Diary* and *Natural History Address Book*. All are exactingly reproduced from the hand-colored plates and hardbound in an elegant volume. These extraordinary plates were selected from the finest examples of 18th and 19th century natural history art in the rare book collections of the American Museum of Natural History, the British Museum, the Royal Horticultural Society, and the Victoria and Albert Museum of London. These two volumes may be ordered separately or as a set. Makes a superb gift.

☐ Yes, I would like to order the 1986 Natural History Diary and/or the Natural History Address Book. Price for the Address Book is $19.50; Price for the Diary is $18. For the set, $35. No charge for shipping and handling.

Barbados Odyssey

Many emigrants fulfill their dreams by returning home

by George Gmelch

In 1968, Wayne Beckles, age twenty, single, and without prospects of a steady job, emigrated from his native Barbados to the United States, to live in New York City's borough of Brooklyn. Over the next nine years he held various manual jobs—handyman in a family grocery story, machine operator, deliveryman—while attending night classes at the City University of New York. After receiving his B.A. degree, he was hired as an accountant by a small firm in Queens. He married Norma Cumberbatch, a Barbadian emigrant, and they started a family.

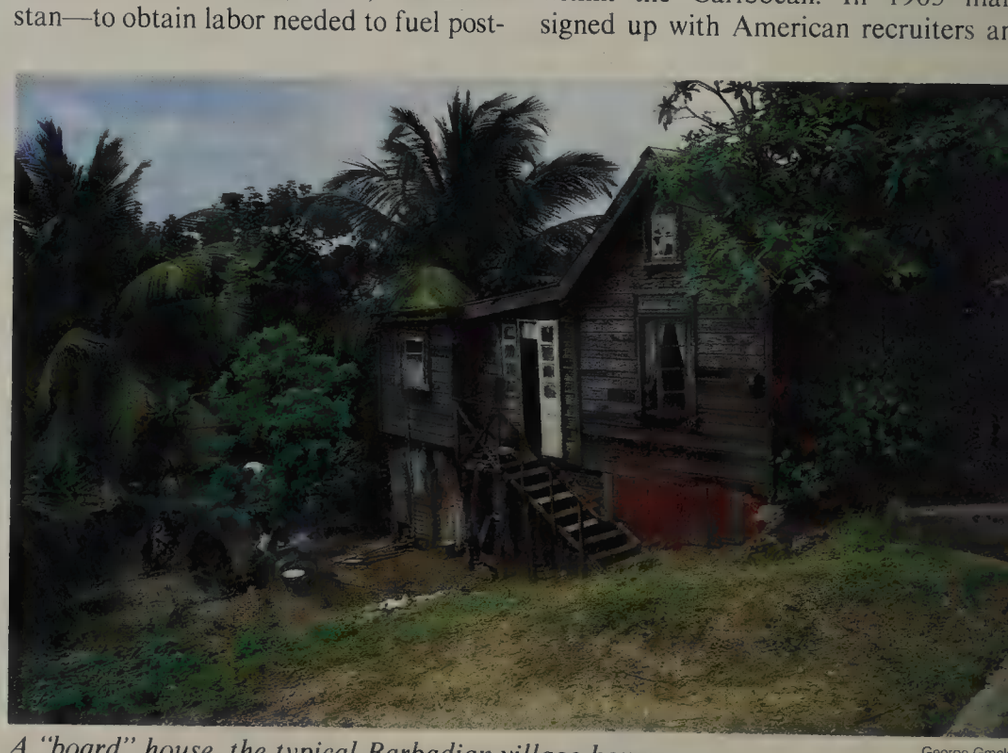
On a visit to Barbados during Christmas 1980, the couple started to talk seriously about going home. Norma didn't want to raise her children in urban America, and Wayne missed the Caribbean climate and outdoor living. So he began to apply for jobs advertised in *The Advocate*, a Barbadian newspaper that circulated among his emigrant friends. Eventually he landed a job as accountant for a sugar company. "I agonized over the decision," he said. "The salary was only half what I was making in the U.S., but my wife insisted that what mattered was which country we wanted to rear our children in." In 1982, Wayne Beckles, with a profession, savings, and fourteen years experience in a metropolitan society, took his family home to the West Indies.

The Beckleses are among tens of thousands of emigrants who in recent years have returned to their native lands. During the past decade there has been a counterstream of migrants returning from Britain and North American to many parts of the Caribbean, including Puerto Rico, Jamaica, and Trinidad, as well as Barbados and several smaller islands. One survey found that 13 percent of all Barbadian men, and half as many women, have lived abroad for more than a year, mostly in Britain or the United States. The actual number of emigrants returning for good each year to countries like Barbados can only be estimated because, as they pass through airport customs and immigration, they are indistinguishable from those returning solely to visit. But there is ample evidence from other sources—the transfer of foreign bank deposits, construction of new housing in rural areas, and population increases beyond natural growth—that return migration is rising sharply in much of the Caribbean.

The phenomenon is not unique to the West Indies. Southern Europe, particularly Spain, Portugal, Italy; and Turkey, has also seen the tide turn. The 1973–74 recession in Europe, induced by the oil embargo, contracted the northern European labor market, slowing emigration from the south to a trickle and causing many emigrant workers to go home. Some went of their own accord; others were encouraged to go home with cash incentives from governments that no longer needed their labor. The European economies have since rebounded, at least partly, but the return flow has not abated. The Portuguese government, for example, estimates that 30,000, or about 6 percent, of its 500,000 expatriates are returning home each year.

Barbadian emigrants left the island as part of a mass migration from the English-speaking Caribbean to Britain and North America following World War II. Most sought jobs; some went to attend university. In the 1950s Britain began actively recruiting workers from its former colonies—the West Indies, India, and Pakistan—to obtain labor needed to fuel post-war reconstruction and a booming ec omy. The London Transport Agency, example, opened an office in Bridgeto the capital of Barbados, to recruit bus c ductors and ticket collectors. In the m 1960s, the destination of Barbadian e grants shifted to North America. Britain, competition in the workplace a hostility and resentment toward "colore immigrants led to the passage in 1962 the Commonwealth Immigration A which restricted further emigration. the late 1960s, the flow of emigrants fr the West Indies to the United Kingdo had virtually ended. At about the sa time, however, the United States a Canada opened their doors. Altogeth between 1951 and 1970, 14 percent Barbados' population of 230,000 left t island.

This was not the first time Barbadia had emigrated from their island. Ev since the 1830s, when slavery was ab ished throughout the English-speaki Caribbean, migration has been comm and widespread. On Barbados and oth islands with similarly dense populatio and scarce resources, emigration is a ne essary safety valve. In the nineteenth ce tury, Barbadians went to larger islan within the Caribbean. In 1905 ma signed up with American recruiters a



A "board" house, the typical Barbadian village home

George Gmel

Reasons for seeing Europe this fall keep piling up.

As the leaves turn russet gold and cover Europe with a winter coat, the throngs of summer visitors head for home. The long lines vanish. And Europe goes native once again.

London fills with bowler hats and brollies. The Champs Elysées rings with Parisian gossip, and peace settles over the Sistine Chapel.

The crazy, heady summer sun gives way to gentle autumn. And with the heat go the prices.

An already reasonable Europe now becomes ridiculously good value, in the shape of TWA's Getaway® Vacations.

Book before December 1, 1985, and a fifty dollar rebate will give you eight days in London for $79–$198, Rome for $68–$168, Paris for $139–$228, or the Costa del Sol for $99–$189,

depending when you travel. That doesn't include your airfare, but it does include a budget hotel (per person, double occupancy), breakfast every morning, a sightseeing tour, and, where possible, free theatre, musical and nightclub tickets. For a copy of our fall and winter vacation brochure, call 800-G-E-T-A-W-A-Y or your travel agent.

Then watch while the summer hordes turn quietly green.

TWA GETAWAY® VACATIONS
LEADING THE WAY.sm

emigrated to Panama to dig the canal. According to geographer Bonham Richardson, by the time the canal was completed in 1914, approximately one-quarter of all Barbadians had traveled to Panama. In the 1920s, Barbadians emigrated to Curaçao, Trinidad, and Venezuela to work in the newly developing oil fields. Others went to Cuba to work in the sugar industry. And even before World War II, a small number had emigrated to England—the "mother country"—and to North America. But the flow to these "metropolitan" countries, as they are referred to in the Caribbean, was only a trickle compared with the torrent that followed after the war.

After working abroad for anywhere from one to thirty years (the average was twelve years among the 135 emigrants interviewed for my study), Barbadians are returning home. A few are pushed home by unfavorable conditions abroad—unemployment, racial tension, and personal problems. The British economy has been recovering slowly from the last recession (1979–82), and what gains have been made have done little for West Indians. The unemployment rate among West Indians in British cities is triple that of whites. Jobs for young West Indians are so scarce that, in an ironic reversal of their own parents' emigration, some who were born and raised in England are now leaving to seek their fortune in the Caribbean.

West Indians have been disturbed by new signs of racism in Britain, such as the rising popularity of extreme right-wing groups like the National Front. The rhetoric and policies of Margaret Thatcher's conservative administration have also contributed to the West Indians' growing uneasiness. Some right-wing members of Parliament have recently proposed that the government encourage West Indians to go home by offering them money. One forty-year-old returnee said that the final straw for him was the British Nationality Act of 1981, which determined that children born in Britain of West Indian parents would no longer qualify for British citizenship. "The notion that my children," he said, "would not be citizens of the country that I had given the best years of my life to was a slap in the face."

Some return migration is precipitated by a personal crisis: breakup of a marriage, death of a spouse, trouble with children, ill health. A hotel maid in an English resort town, who returned after being divorced, told me, "After my husband left, it was just me and kids in the house, and that's not good for anybody. I was lonely and bored. We needed more relatives around." An engineer in the London Post Office returned when his wife developed severe allergies; a construction worker in Toronto came home after suffering a stroke; and a mechanic in Brooklyn brought his family back when his mother in Barbados, was diagnosed as having cancer. In Britain, doctors often advise West Indians with serious health problems, especially mental disorders, to reemigrate. The change of scene and climate may be good for the patient, but it also helps to reduce the burden on the National Health Service.

While some emigrants go home because they are unhappy with their lives abroad, the vast majority return because of their attachments to Barbados and its people. One elderly man, chewing a stick of sugar cane as he spoke, told me, "The money was good [in Canada], and the people treated me with fairness. But in the end I wanted to be home with my own people, in my own land." Many emigrants want to be near aging parents and old friends again. Others have patriotic reasons. A woman who graduated from Colgate University and worked as a housing research analyst in Washington, D.C.

eturned to Barbados to teach high school. "Barbados is a developing country," she aid, "and I felt that any contribution that make in my lifetime, I want to make ere." Emigrants also miss the warm, unny Caribbean climate. Returnees I interviewed frequently complained about he long, cold, dark winters of the northern ities where they had settled—New York, oronto, Montreal, London, Birmingham.

For many emigrants, return migration s best understood as merely the fulfillment of what they had always intended to o, the natural completion of the migration cycle. At the time of their initial emigration, most Barbadians only plan to be away long enough to save money to buy a ouse and perhaps a car or to acquire a ollege degree or a trade. Despite such intentions, however, only one of every four migrants from Barbados ever manages to eturn home for good. Some simply cannot afford the passage or plane ticket back o Barbados. In any case, those who fare oorly overseas are disinclined to return ecause they will lose face—all emigrants re expected to come home with at least nough money to buy a home of their own. nd unless they are receiving a pension, ost migrants will not return home without good prospects of a job. Because Barados has scarcely any benefits for the unmployed, they are better off staying broad. Conversely, the very successful lso seldom return. To do so would mean iving up well-salaried positions and a tandard of living that cannot be equaled n Barbados. It can also mean costly obgations to share the wealth with less-well-ff kinsmen at home.

Are those who return merely adding to he island's overcrowding (with 1,480 peole per square mile, Barbados is one of the ost densely populated nations on earth) r do they contribute to development? Many who have studied the impact of reurn migration on villages of the Third Vorld have argued that returnees seldom ring back work skills that are useful in he homeland; play a minimal role, at best, introducing modern ideas; and rarely invest their overseas savings in new enterrises that create jobs or benefit the reion. But most of these conclusions have een drawn from research conducted in ural areas, where the focus has been on easant or worker migrants. College-eduated and technically trained migrants ettle in towns and cities, where they seek he kinds of white-collar jobs they had broad. This group of return emigrants ay play a different role.

Barbadian emigrants do bring home ew attitudes and ideas. Even Barbadians ho have never been away concede that

Only Swan Hellenic offers you...

THE EARN BOAT™

Learn your way around on a 17 day or 29 day Mediterranean vacation with 5 guest lecturers.

22 VACATION VOYAGES VISIT 180 PLACES.

Each Swan Hellenic vacation combines places you know about with others you'll want to learn about.

These sites and settings are linked to ancient legends, myths and history. You can explore the remains of Greek, Roman, Byzantine, Ottoman and Islamic civilizations.

That's why Swan Hellenic takes along guest lecturers. They offer authoritative and relevant information on the empires you'll trace.

You'll learn so much listening to these experts, you don't need to be a historian or an archeologist to thoroughly enjoy this unique vacation.

You can see the Mediterranean from whole fleets of boring cruise ships. Or, you can learn your way around with Swan Hellenic.

Ellen Frankenstein

Young Barbadian men at a village rum shop

returnees are more "broadminded" and experienced than people who have never emigrated. They generally have a heightened sense of justice, stand for better treatment of women, are less tolerant of racism, and have a more developed sense of West Indian nationalism. They are also said to be more willing to support unpopular causes. Many Barbadians also believe that returnees are more ambitious, harder working, and more goal oriented.

But it is difficult to prove that returnees' attitudes rub off on their neighbors. Barbados is a conservative society where people are slow to accept change, especially "foreign" ideas brought back by their own countrymen. "When proposing some change to my parishioners," said an Anglican rector, "I have to be very careful not to let them think I learned it in England." One middle-aged civil servant who had returned from London talked about his superiors who had never been away: "Because you've been away and maybe know more about something, they feel threatened. They don't want to admit that you have the answer, especially when you've been on the job half as long as them." Another man said of emigrants:

> They have the same ideas as the North Americans who live here. The difference is that local people will listen to what the foreigner has to say, but not to their own kind. They'll say, "Who is he to tell us what to do, he's only a Barbadian like us!"

As a general rule, material items are more easily transferred than ideas from one culture to another. In an earlier period, Barbadians returning from work on the Panama Canal with what local Barbadians referred to as "Panama money" introduced window screens and improved sanitation. But today's returnees are introducing little in the way of new items—other than their curious use in a tropical climate of wallpaper and wall-to-wall carpeting, neither of which has been imitated by other Barbadians. As a group, however, the returnees who have become accustomed to new technology abroad are themselves quicker to accept new ideas and goods when they appear in Barbados.

One problem with assessing the influence of returnees in the larger community is trying to disentangle their role as agents of culture change from all the other external influences on Barbadian society. Barbadians today have so much contact with the outside world through films, foreign television programs, tourism (the number of foreigners visiting the island each yea exceeds the population), and travel tha there is little that migrants can introduc that the locals have not already seen.

But return emigrants do have an impac in another way. After years of hard work most emigrants arrive home with a sizable amount of capital, from savings and from the sale of overseas assets, such as a house a car, and furniture. To save money, many emigrants set aside a fixed percentage o their weekly paychecks to be deposited in a savings account or sent home to Barbados for safekeeping. Blue-collar emigrants often set up small, informal credit associations, known as a partner or meeting, in which each of a dozen or so members contributes about $8 to $10 per week. Periodically, each member gets a lump sum. Emigrants say it is difficult to save small amounts of cash, whereas the lump payment is large enough to put away.

Most returnees use their savings to purchase a house. Those who already own homes add a room or buy new furnishings and appliances. Those who can afford it also buy a car, an important status symbol among middle-class Barbadians, who shun public transportation. This display of wealth, where locals remember the emigrant's humble backgrounds, sometimes causes jealousy and friction. Granville Hunt, for example, resettled his family in his boyhood village on the Atlantic side of the island, an area still untouched by tourist development. With their overseas savings, the Hunts refurbished the family rum shop, which had stood vacant during their absence, and bought a house overlooking the Pentacostal Church. Unlike most houses in the village, which are built of wood and have corrugated iron roofs, the Hunts' house is masonry with a til

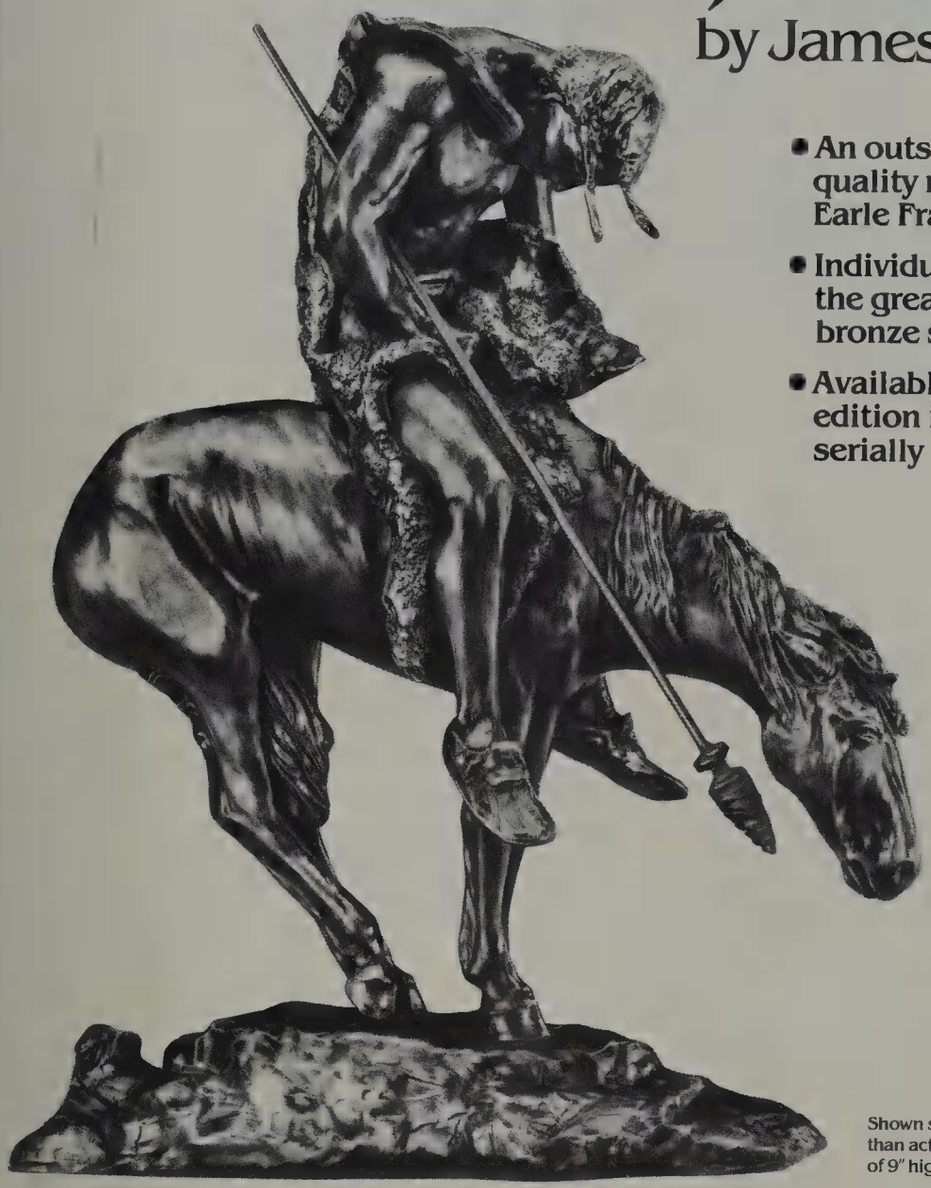
"The End of the Trail"

by James Earle Fraser



- An outstanding museum quality reproduction of James Earle Fraser's greatest work.
- Individually hand-finished in the great tradition of classic bronze sculpture.
- Available in a single limited edition issue of just 9500 serially numbered sculptures.

Shown smaller than actual size of 9" high.

One of the most beloved and acclaimed sculptures in American history, "The End of the Trail" is James Earle Fraser's world renowned tribute to the American Indian. The few existing bronze originals are virtually beyond valuation, but now this magnificent ⅓ size museum quality reproduction is available for the exceptional offering price of just $195.00 per sculpture.

This extraordinarily detailed and faithful reproduction has been created under the direct supervision of Ms. Christine Roussel — former Director of the Reproduction Studio of the Metropolitan Museum of Art.

Each "End of the Trail" sculpture will be meticulously crafted of cold-cast bronze — a remarkable medium that holds even finer and more intricate detail than traditional hot-cast bronze. Every sculpture will be individually cast from a special blend of powdered resins and bronze, then hand-finished with a classic patina, similar to the original. Each "End of the Trail" will be hallmarked and serially numbered. A Certificate of Authenticity will accompany each sculpture.

The edition will be strictly limited to just 9500 pieces worldwide and after that, all molds will be destroyed forever. To reserve this important Limited Edition Fraser reproduction, simply return the reservation application below. No payment need accompany your order at this time.

George Gmelch

In Barbados, once a slave colony, houses represent freedom, security, and high status

roof. It is twice the size of the other homes in the village and equipped with modern kitchen appliances and a stereo. Painted cornflower blue, it stands on the hillside like a beacon, beaming to one and all the Hunts' success as emigrants. The family's Oldsmobile, which dwarfs local vehicles and is more than half the width of most village streets, is also a reminder that the Hunts have made it.

The Hunts' ostentatious return has brought them trouble. Relatives and friends who had always been friendly during vacation visits are now jealous. Village gossip has it that the Oldsmobile and house are the result not of hard work and saving but of winning a lottery. Villagers rarely come to the rum shop, lest they add to the family's weath. "Even the people from our church don't shop here," said Mrs. Hunt.

> They don't want us to have their business. You can't win. If you come back with money, they are jealous. If you come back with nothing, they ridicule you. . . . When I was a poor shopkeeper [before emigration], we had more friends than we have today. You see, then we were all at the same level.

Some anthropologists argue that it would be better if emigrants like the Hunts invested their savings in enterprises that create new jobs and capital in their home societies. In Barbados, however, such criticisms carry little weight. As in all former Caribbean slave colonies, property ownership is associated with freedom, economic security, and high status. The reason most Barbadians go abroad in the first place is to earn enough money to someday buy a home of their own. And it is through home ownership that returning emigrants communicate to friends and neighbors that they have been successful. This is largely the reason emigrants usually purchase or build "wall," or masonry, houses, rather than the lower-status "board" houses that resemble those they were raised in.

Only one in seven Barbadian returnees invests his savings in a business. A 45-year-old migrant, for example, spent $16,000 he had saved during five years in Montreal to set up an auto body repair shop. Another returnee opened a typewriter repair shop. Still another man had a fishing boat built with money earned on an assembly line in England; he now employs several men to work it for him. Other migrants who brought cars home from abroad are now taxi drivers. Although the businesses the returnees have established do provide needed services and contribute to the smooth running of the economy, they generally are not novel enterprises and do not employ many people.

But many emigrants have returned to take professional and highly skilled jobs in the workplace, benefiting their society in important ways. Most emigrants return to Barbados with a higher level of work skills and training than they had before they left. One third of those in my sample had gone to college while abroad and nearly as many others received on-the-job technical training. Fifty-five of the migrants interviewed (about 40 percent) work at professional or technical jobs in Barbados, whereas only 9 percent of the total Barbadian population fall into this job category. And while 31 percent of the island's population work at unskilled jobs in manufacturing, only one percent of returnees do. The president of a Bridgetown computer firm said, with some exaggeration, "There's nobody in business in Barbados who is moving up, who has not been away." Barbados' past three prime mini ters, more than half the current membe of its parliament, and most of the profe sors at the island's University of the We Indies campus are return emigrants.

Those who have had the most impa have been professionals and manage with the authority and freedom to put in practice the ideas and techniques the learned abroad. The others, the worke on the shop floor rather than the bosses the front office, usually lack the power change things. A diesel mechanic traine in England and now employed in one Barbados' six sugar factories, for exar ple, found that he knew much more abo his job than his workmates but noneth less had little effect. His fellow worke were not interested, he said.

> If you tell them something new, they thi you're trying to fool them. The guys he don't wear protective clothing when they' welding, and the factory won't make the until there is a serious accident. I've tried show some of them that they should do the right way, to look after themselves they'll get injured. Some listen, but mo don't.

In short, the impact of the blue-coll returnee to Barbados is like that of retur ees in rural areas in other parts of t world. But white-collar, college-educat returnees have made numerous innov tions in their jobs, generally in the areas computers, medicine, and engineering, f which no graduate training is offered Barbados. An American-trained accou tant, now the head of the accounting d partment in a Bridgetown firm, intr duced electronic processing of the firm accounts, following the model he h learned in New York. Another accounta introduced a new audit procedure he h learned while working in London. Follo ing his return from Montreal, an obstet cian introduced new techniques for mo toring babies before birth. A rector w returned from England to assume the s nior position in one of Barbados' elev parishes instituted new policies to increa the participation of parishioners in chur services. A movement to deinstitution ize child care in Barbados came from in viduals in the Ministry of Social Servic Board of Child Care who had become f miliar with a new approach while worki in Canada. In these and other ways, retu migrants have shared their gains abro with their fellow Barbadians.

George Gmelch is an associate profess of anthropology at Union College, Sch nectady, New York. He has also done r search on return migration in Newfoun land and Ireland.

Wild radish lacks the swollen root of its cultivated relative but, like many weeds, produces showy wildflowers.
Frank S. Balthis; Nature's Image

Radishes Go Wild

The country cousin of the garden radish is a weed with a difference

by Norman C. Ellstrand

You see one weed, you've seen them all. Or have you? At first glance, every dandelion in a lot, every clump of crab grass in your yard, looks pretty much like the next. Some plants may be a little bigger or have a few more leaves, but these superficial size differences, due to the vagaries of the plant's environment, are about the only major variations apparent among members of a local weed population. The basic and dramatic differences of genetic origin, while well known between separate weed populations, for example, those a few miles apart, are not expected among weeds of the same species growing in the same field.

Ecologists have long accepted this pattern of nonvariability. The quick growth, quick demise weedy life style affords separate plant populations little opportunity to exchange seeds and thereby acquire genetic diversity. The black mustard in the empty lot across the street may be descended from only one or just a few seeds. And only a few seeds from that population may go on to start a colony in the next lot. It's like planting your garden with multicolored zinnias and giving your neighbors only a few seeds produced by your plants to start their own garden. Even if you started with a good deal of variety, your neighbors would end up with one or two predominant colors. And if they gave *their* neighbors seeds in a similar fashion, almost all of the yards would have a uniform hand in only one or two generations. Thus, even for those of us who love them, weeds, as a rule, can be monotonous.

But wild radish flagrantly breaks the rules. Like confetti blown in from a New Year's Eve party, the multicolored flowers of wild radish—pink, white, yellow, purple, bronze, brick—deck the vacant lots and fallow fields of California each spring. Close inspection reveals that, beyond color, petals differ in shape, vein color, and even angle of spread. Leaf shape and hairiness, as well as the texture, shape, and color of the multiseeded pods, may vary. These differences are genetically, rather than environmentally, based. That is, the differences are coded in the genes, not coaxed out by the plant's immediate surroundings. With all of their variety, individual plants in a wild radish population can be distinguished almost as easily as faces in a room. The presence of such abounding diversity is as surprising to plant ecologists as finding Easter eggs in a carton marked Grade A, Large White.

Why, and how, do wild radishes break the rules, and how do our assumptions about uniformity of weed populations hold up in light of this evidence? The thrust of my research has been to answer these two questions by asking two more: how much genetic information can be borne by the seeds within the radish fruit, and how likely are gene-bearing pollen and seeds to be transported from one weed population to another? Although both of these factors—genetic information within fruits and long-distance mating—can create variation, neither had been measured directly in any natural plant species.

The seeds of most weed plants are dispersed individually in single-seeded fruits, from the grains of grass stuck in your socks to the plumes blown off a dandelion head. But in wild radishes, the fruit—a tear-shaped, thick, styrofoamlike pod that never opens, called a loment—generally bears from two to eight seeds. Since the fruit is the vehicle for founding a population, radishes will always start with more individuals per vehicle than the typical weedy species.

But the amount of genetic information in each fruit depends on both the number of seeds in the fruit and the number of parents contributing to those seeds. All the seeds share the same mother, but they may have different fathers. A radish fruit containing eight seeds can carry the offspring of as many as nine parents (the mother plus a different father for each seed) or as few as two (the mother plus a single father). The effects of single versus multiple paternity can be compared by considering the analogy of giving zinnia seeds to your neighbors. If you gave each neighbor half a dozen seeds from a single plant, all of the neighbors' resultant plants are more likely to have the same flower color than if you gave them one seed each from six different plants. In the same way, if a radish fruit bears the seeds sired by a single father, each fruit founding a new population some distance away will represent a fairly narrow array of genes, not very different from other weeds with their single-seeded fruits. But if the seeds are sired by several fathers, then each "colonization" will involve genetic information from several individuals.

Can we expect radish pods to pack an assortment of genes? Until recently, virtually nothing was known about the paternity of seeds within the multiseeded fruits of any plant species, but zoology and pollination ecology offered some clues. The number of fathers contributing to the seeds of a fruit is biologically analogous to the number contributing to the offspring in the brood of an animal species. Multiple paternity is now known to exist in a wide array of animals from sowbugs to lobsters, fruit flies to spiders, snails to squirrels. Futhermore, pollination ecologists have discovered that pollinators frequently carry pollen from a number of plants, rather than unloading all of one plant's pollen onto another. Both observations suggest that multiple paternity could be common in plants.

A painted lady butterfly alights on a wild radish blossom. Such flying pollinators may be carrying pollen from distant, as well as nearby, flowers. If pollen grains from different sources are deposited at the same time, the seeds in the resultant radish fruit may have several different "father" plants.

Maureen Stanton

Most weeds show little variety; wild radishes are an exception because no one plant typifies the species. Wild radish flowers blooming in the same field often vary in hue, shape, and even vein color.

Diane L. Marshall

But other studies show that after being deposited on the stigma of the "mother plant," pollen may germinate and produce tubes that grow at different speeds. For example, a bee may deliver a mix of pollen from a variety of sources, but most likely all or most of the seeds of a fruit will share the one father whose pollen tubes grow the fastest.

When my research associate Janet Lee and I asked whether multiple paternity was possible in wild radish, we had no preconceptions. Our goal was to identify the father of each seed within a fruit in order to directly count the number of fathers contributing to that fruit.

We chose to study a small, isolated wild radish population at the University of California's Agricultural Field Station in the Moreno Valley. All of the flowering plants within this radish population were typed for chemical genetic markers called allozymes. The advantage of using chemical allozymes, instead of characteristics such as fruit shape or flower color, is that allozymes are inherited simply, expressed in both parent (flower) and progeny (seed) tissue. Furthermore, this procedure is cheap and efficient. After we harvested the mature fruits, we identified the genotype (genetic makeup) of each of the seeds of several fruits. Because we already knew the mother's genotype, we were able to subtract that from the genotype of the seed. The remaining genotype comprises the father's genetic contribution. We then compared the father's contribution with the genotype of every plant that had flowered in the population because these comprise the possible fathers. Geneticists use the same approach to exclude a possible father (or fathers) in a paternity suit.

In this way, we were able to assign each seed to one or a few possible fathers. When these possibilities were compared for the seeds from a single fruit, multiple paternity was identified in those fruits in which two or more seeds could not have shared the same father.

More than 85 percent of the fruits we tested contained seeds having different fathers. In many cases, three or four fathers contributed to a fruit. A radish fruit that colonizes a new site, landing in a new field, for example, will often contain the genetic information of three or more parents.

My associate Diane Marshall, now of the University of New Mexico, devised a series of experiments to determine how multiple paternity comes about. Marshall and I agreed that multiple paternity could result either from a visit to a flower by a single pollinator bearing a mix of pollen from a number of plants or from repeated

Wild mustard and wild radish belong to the same family and are commonly found together in weedy fields, right. Unlike radish flowers, wild mustard flowers are alway yellow. Below: The wild radish is a hybrid descendant of the cultivated radish and the jointed charlock, closely related plants that were introduced into California in the nineteenth century.

Steve Solum; Bruce Coleman, Inc.

visits by different pollinators to a single flower, each bearing pollen from a different plant. Marshall's experiments revealed that fruits produced from a single pollination involving a mixture of pollen from different father plants very often resulted in one fruit containing seeds with different fathers. But fruits produced by sequential pollinations with pollen from a variety of donors had fewer fathers, even when pollen from a second source was delayed by as little as fifteen minutes. If the delay was more than an hour, there was hardly ever more than one father per fruit. Because the average interval between pollinator visits to a single flower in nature is more than two hours, Marshall concluded that the most likely cause of natural multiple paternity was transport of pollen from different plants by the same pollinator.

The ecological advantage of multiple paternity later became clear. Marshall found that multifathered fruits produced both more and larger seeds than those sired by any single father, even the father producing the largest and most numerous seeds. Maureen Stanton of the University of California at Davis had already shown that large wild radish seeds have a better opportunity to germinate, grow, and reproduce than do small seeds. Frequently produced, multiply sired fruits are therefore likely to be the better at colonizing new fields because they bear the larger seeds.

Long-distance pollen exchange could also foster variety. We can return again to the case of the neighborhood's multicolored zinnias. Each of the neighbors had only one or two colors of zinnias in their gardens, but taken together, the gardens have dozens of colors. If neighbors began a program of exchanging even a few seeds each year, in a few years most of the variation available would be present in every garden. Similarly, pollen exchanged between natural populations could create a blend of diverse wild radish genotypes.

Are wild radishes from different populations likely to mate? The answer depends on the activity of the radish's pollinators. Insects such as butterflies and moths (for example, painted ladies, cabbage butterflies, skippers), bees (honeybees, bumblebees, carpenter bees), syrphid flies, and even the odd beetle pollinate wild radish. The primary insect species responsible for pollinating these weeds can vary over a few miles or a few weeks. And while all of these insects are capable of flying for miles, the frequency of long-distance flights is hard to measure.

Traditionally, pollination ecologists have described mating patterns for insect-pollinated plants by watching insects as they move among mapped plants within a population. Compiling these plant-to-plant moves, ecologists have inferred that the vast majority of mating distances are very short, generally on the order of one to a few yards. Interpopulation matings, then, should be extremely rare, representing far less than one percent of the total seeds produced in any generation. But episodes of these matings are next to impossible to count by following insects, as this would involve simultaneous monitoring of all of the edges of a population for the arrival of pollinators.

The genetic approach to paternity, in contrast, makes for easy identification of those seeds resulting from interpopulation mating. Because the father's genetic contribution can be described directly and compared with all possible local fathers, a contribution that doesn't match any of these must have come from another population. Lee, Marshall, and I studied a di ferent population of wild radishes in eac of three years. The first two populatio were isolated from the next nearest radis by well over half a mile, the third by mo than one hundred yards.

We found the frequency of long-di tance matings to be more than 8 perce for the first two populations and almost 1 percent for the third. Such rates are hig enough to introduce plenty of genetic var ation into a wild radish population withi just a few years.

Why does wild radish break the rule Multiple paternity and long-distanc matings, our two possible sources of th tremendous genetic variation in wild ra ish populations, explain why wild radis stands apart. Other factors, however, ma also be involved. A bank of previously u germinated seeds in the soil may add th genetic "memory" from former popul tions. Also, long-distance migration fruits may take place more often than commonly thought.

You can expect to be hearing mo about the ecology of the wild radish, i cluding how diversity, once achieved, maintained in wild populations. Easy t find, easy to grow, and easy to manipulat wild radish is an ideal research plant tha still retains some secrets.

Whales That Go to Extremes

North Pacific humpback whales bang heads on the mating ground, but when they get to the feeding ground, they put their heads together

by C. Scott Baker and Louis M. Herman

Often portrayed as a gentle giant, wooing its mate with a song, or as a solitary nomad, wandering the oceans in search of food, the humpback whale is proving to be neither. Instead, we are finding that these leviathans are, by turns, more contentious and more cooperative than we ever imagined them to be.

Humpback whales are a cosmopolitan species, with major populations in the Pacific, the Atlantic, and the oceans of the Southern Hemisphere. Like most baleen (filter-feeding) whales, they migrate between summer feeding grounds in near-polar waters and winter breeding grounds in warm equatorial waters. Nearly 6,000 miles round trip, this annual migration is one of the longest made by any mammal. The thousands of humpback carcasses studied by biologists over the years have provided evidence that the species reproduces seasonally and fasts seasonally. In other words, little or no feeding takes place on the breeding grounds during the winter and little or no breeding takes place on the feeding grounds during the summer. For up to six months each year, during migration and while on the wintering grounds, humpback whales rely on vast stores of lipids, in their blubber and other tissues, to meet their energy demands. They feed on the enormous schools of prey found in their summer retreat from June to early October to replenish their fat reserves and prepare them for another migration south.

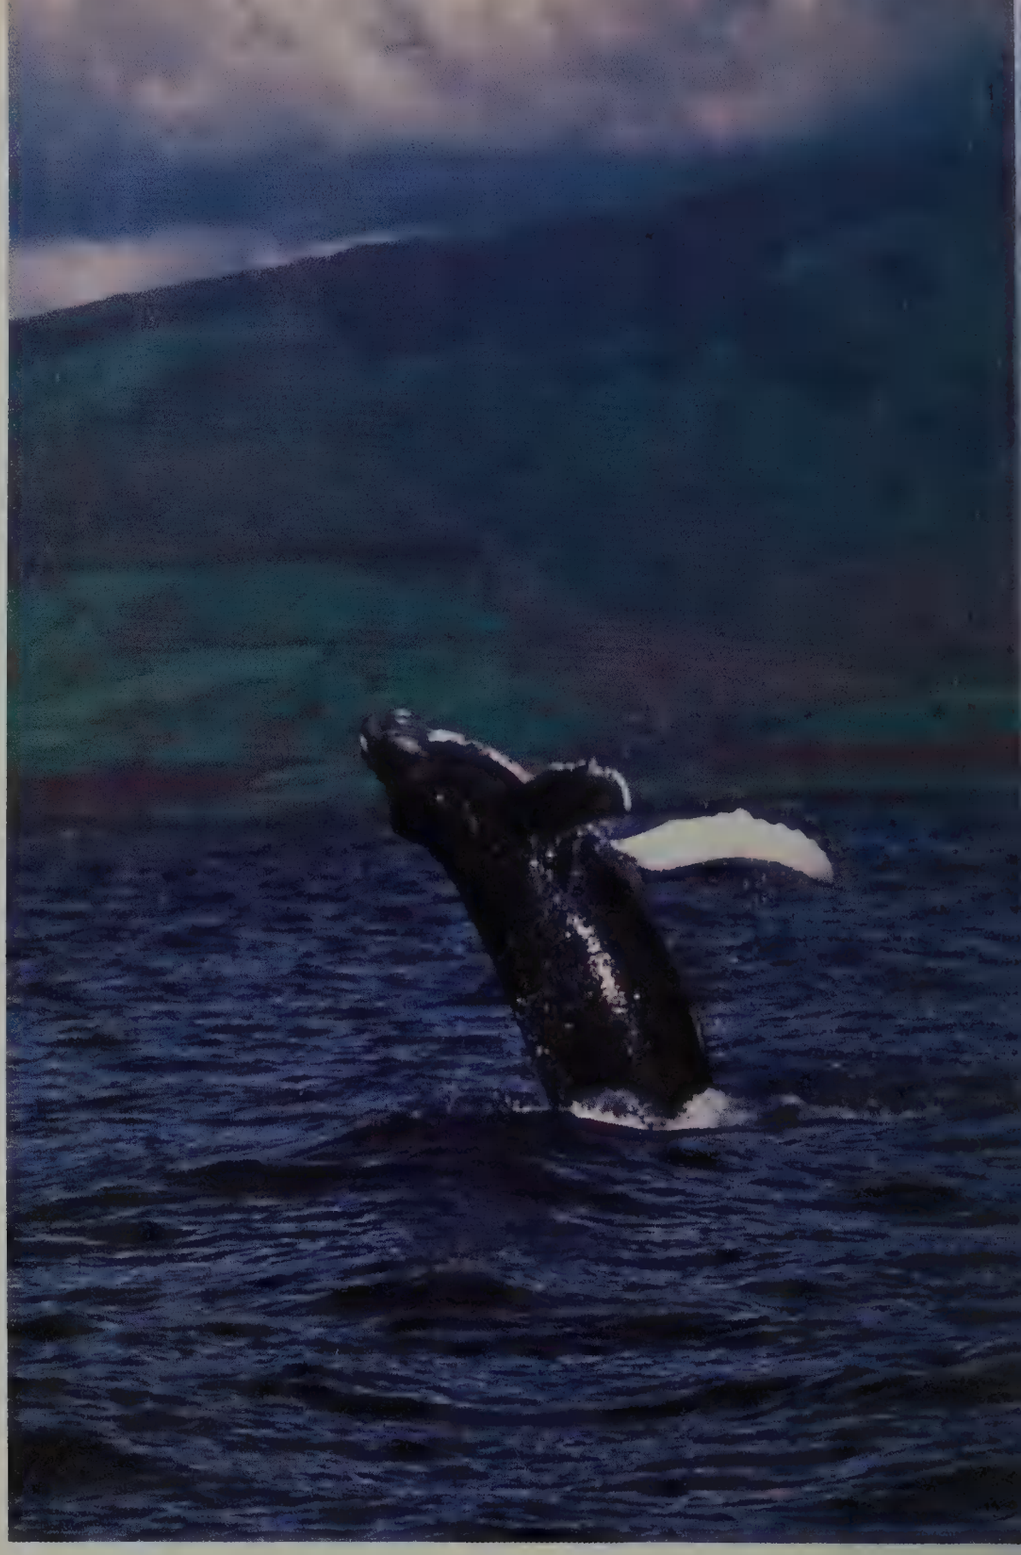
Along with our associates Anjanette Perry, Gordon Bauer, and Paul Forestell of the University of Hawaii, we have studied the migration and social organization of humpback whales in the northern Pacific Ocean for the past ten years. In the summer this study takes us to the calm inshore waters of southeastern Alaska, where an estimated 300 humpback whales go to feed each summer and fall. In the winter we return to Hawaii, where perhaps 500 to 1,000 whales gather to breed and raise their newborn.

Until recently, a major obstacle to understanding the social behavior of humpback whales was the difficulty in determining the sex of individuals. Male and female humpbacks look almost exactly

A feeding group of humpback whales lunges through the surface, taking great mouthfuls of food—usually schooling fish or krill—and sea water. By coordinating their movements, groups of whales may feed more efficiently than solitary eaters. Humpbacks fight during the winter breeding season in Hawaii, but they tolerate each other on their Alaskan feeding grounds from June to October; many team up year after year to fish collectively.

Jan and John Straley

Mark Ferrari; Earthviews



alike; the only way to be sure of an individual's sex is to inspect its genitals. While whalers could easily make this sort of inspection on their flensing decks, the task is considerably more difficult when dealing with whales in the wild.

Fortunately, repeated sightings of individual whales can provide indirect evidence of an animal's gender. By examining photographs of the unique black-and-white patterns on the underside of the tail flukes, we have been able to identify more than 1,200 individual whales in the eastern and central North Pacific. Details of where the animal was sighted, who it was associating with, and what it was doing are stored in a computer library at the University of Hawaii. From these records we can now surmise the sex of several hundred whales.

Observations of the individually identified whales in Hawaii and southeastern Alaska reveal a complex and variable social organization linked to seasonal migration. In Hawaii, the structure of humpback groups centers on male competition for mature females. We often observe aggression when a cow-calf pair is joined by one or more adults. But since the behavior of such escorts is sometimes defensive and sometimes aggressive, we were initially unable to figure out whether they were males courting the cow or females related to her—"aunts" helping to protect the calf. Related females in many other species of long-lived mammals, including dolphins, chimpanzees, and African elephants, help each other in this way. We have observed, however, that the same escort rarely accompanies a cow-calf pair two days in a row. If the escorts were aunts, we would expect them to be with the cow on a regular basis. The brief associations suggest instead that escorts are mature males courting the cows. More direct evidence of this has come from Debbie Glockner-Ferrari, an independent researcher in Hawaii, who has determined the sex of escorts by photographing them under water.

The majority of cow-calf pairs in Hawaii have one or more escorts. A lone escort typically stays behind, and a little below, the cow-calf pair. If another escort attempts to join the trio, the lead escort tries to maintain his proximity to the cow and keep the intruder behind him. But if the new whale persists in trying to approach the cow, he is met by an escalating series of threats from the original suitor.

The first step taken by the aggrieved male in these hostilities is usually to intercept the challenger and block his approach to the cow-calf pair. This preliminary act of aggression, which probably doesn't bring the whales into actual physical contact, occurs under water and is thus difficult to see. But if the situation heats up a little more, the initial escort may try head lunges as a way of displacing the interloper. A head-lunging whale erupts through the surface and engorges the pleats of its throat with water and air, possibly attempting to increase its apparen size. As Darwin first noted in *The Expres sion of Emotions in Man and Animal* one of the most common elements of ag gressive or defensive displays in verte brates is that the animals try to mak themselves look bigger by puffing up thei fur or by inhaling to inflate body size.

Along with head lunging, competin male humpbacks also release air unde water. This behavior, known as bubblin may have originated as a specialized feed ing strategy. In southeastern Alaska, feed ing humpback whales often blow a cylin drical or spiral-shaped curtain of bubble to help contain or concentrate plankto and small fish. Bubble trails in Hawaii ar formed along a straight or slightly curve path, but the intent may be similar. Lik

The humpback breeding ground is often the site of violent conflicts between males and of spectacular aerial displays. Fights often begin when a male escort accompanying a female is challenged by an intruder attempting to displace him. Below: An underwater scrap between two males bursts out into the open. The original escort (right) was tagging along with a cow-calf pair when the antagonist arrived. Left: A female that was being pursued by several sparring males breaches out of the group. The mountains of western Maui are visible in the background.

Mark Ferrari; Humpback Whale Fund

he bubble net, which is thought to disori-ent the whale's prey, bubbling on the mat-ng grounds may confuse a whale's oppo-nent. Having been caught in bubble trails ourselves while observing whales under vater, we can affirm that even a thin cur-ain of bubbles reduces visibility drasti-cally—often to only a few feet.

If head lunging and bubbling still don't esolve the conflict, the lead male may es-calate to a violent charge-strike, a form of ssault in which one whale butts another vith its rostrum (chin) or strikes out with ts flukes. The tips of a whale's flukes and ostrum are sometimes spotted with bar-nacles, adding a "brass knuckle" effect to he blow. In extreme cases, two butting vhales may rise vertically out of the water n a posture that early whalers described s copulation. Our photographs of vertical vhales, however, show that they are posi-ioned stomach to back, which is not the vay other whales and dolphins are known o copulate. And in some instances we now that both individuals were males. Most likely, the whalers simply mistook ighting between males for mating.

Early whalers also misinterpreted, in nany cases, the function of the humpback vhales' spectacular aerial displays—other neasures the whales sometimes adopt in isputes with rivals. The whalers described breaching, lobtailing, and finning accurately, but most of them thought what they were seeing were "gambols," or play. A breaching whale hurls itself out of the water, twisting its body in mid-air, and then lands with a thunderous splash. When lobtailing, a whale slaps its tail flukes against the surface of the water. Finning is similar to lobtailing except that the whale slaps the water with its long flippers instead of its flukes.

While the aerial behavior of a calf may be play (a difficult situation to define), some aerial displays by adults are clearly part of aggressive encounters. On March 15, 1981, near the island of Maui, we saw a cow-calf pair with four aggressive escorts. We identified the lead escort as Arrow, a male with an extensive history of escorting. For more than an hour, Arrow lunged and physically displaced the other escorts, driving them back from the mother and calf. Following a violent charge-strike by Arrow, one of the trailing escorts lobtailed six times and left the pod. Within a few minutes the others also left, leaving Arrow alone with the pair.

On another occasion, we found a cow-calf pair resting near the surface with a single escort. Another whale rapidly approached the trio and breached when it was a few hundred feet away. The female's initial escort quickly moved to block the newcomer, and the four whales moved off uneasily, the males sparring intensely in an attempt to get in the lead.

Unlike head lunges and charge-strikes, however, a whale's aerial behavior is not used solely for aggression. Breaching, lobtailing, and finning also are used in apparently amicable situations in Hawaii when whales come together or split up. On the feeding grounds in southeastern Alaska, a whale may breach as it joins another whale in feeding. When feeding whales disperse, we often see aerial displays. Hal Whitehead, in his work with humpback whales feeding off Newfoundland, found a similar correlation between aerial displays and changes in the composition of whale groups.

Aerial behavior is related to at least one other circumstance—human activity. In southeastern Alaska, humpback whales may breach or otherwise react strongly to passing ships or boats. Once we watched as a 600-foot cruise ship passed by a pod of three adults and a calf feeding in a small cove. Although the ship remained more than a mile away from the pod, the whales breached twenty-two times in a row as it approached. From underwater recordings made at the time, we found that the breaching was closely correlated with sudden increases in noise resulting from changes in the ship's engine speed.

Because aerial display is part of so many situations—changes in group composition, play, aggression, and human disturbance—it is difficult to pinpoint its function. Like the bark of a dog, breaching, finning, and lobtailing may have different meanings in different contexts.

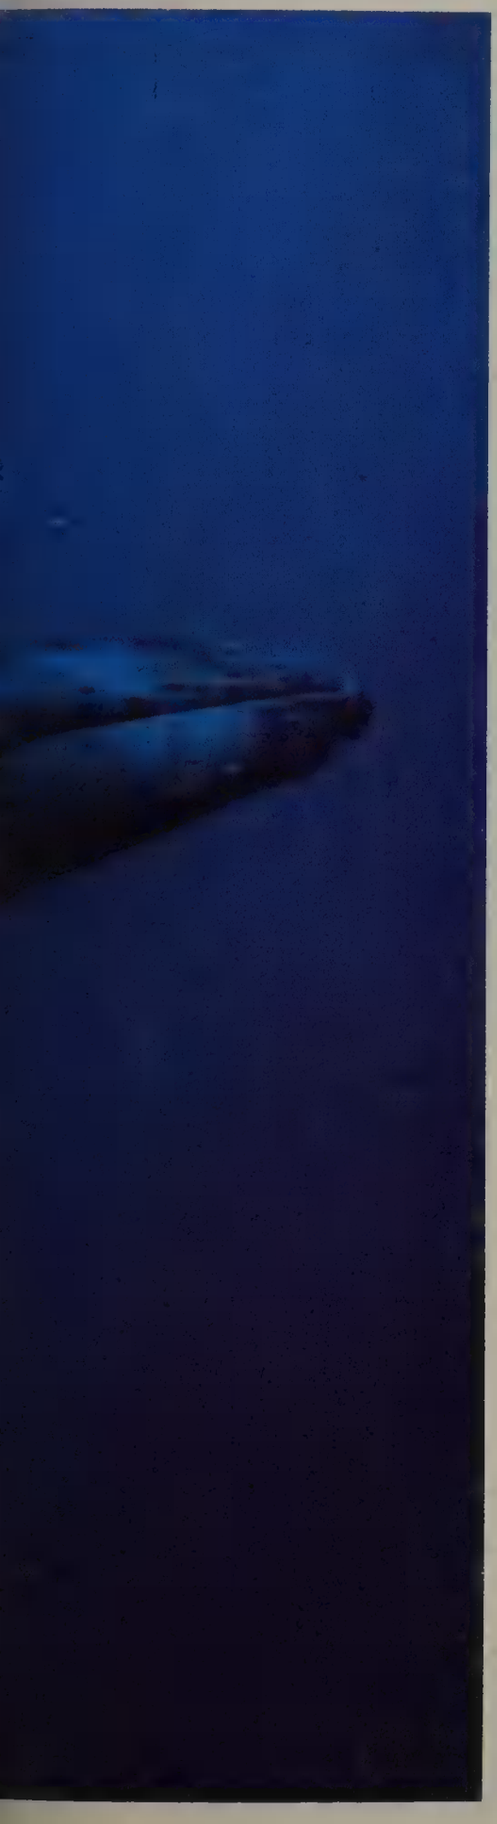
Aggressive encounters between male humpbacks often take place near cow-calf pairs, but males also fight over single females. Most female humpbacks give birth only once every two to three years, so there are seasons when adult females come alone to Hawaii. Large pods of whales without cow-calf pairs are often "surface active," with frequent head lunging, bubbling, and charge-strikes. In some cases, we have discovered a mature female in the lead of these pods with males trailing her. This suggests that surface-active pods are

Off the west coast of Maui, a humpback female and her calf move slowly under water. Calves often remain above their mothers. Females reproduce once every two or three years, so they sometimes come to Hawaii without any young. Whether alone or with calves, females are approached by males that fight to become their escorts and, presumably, their mates.

Deborah A.Glockner-Ferrari; Humpback Whale Fund

A humpback male blows bubbles, one of its strategies for driving off opponents. Bubbling, the release of air from the whale's blowhole or mouth, may confuse a male's rival, for the bubbles drastically reduce visibility. But it may also simply be a threat to an intruding whale.

Deborah A. Glockner-Ferrari; Humpback Whale Fund



aggregations of males competing for proximity to a mature female.

The behavior of escorts with cow-calf pairs and males in surface-active pods closely resembles that of "tending" males in many ungulate species. Among moose and gazelles, for example, a tending male temporarily associates with a preestrous female during rutting season and defends her against other prospective suitors. Like the humpback whale escort with his cow-calf pair, the association between the tending male and female ungulate is brief, lasting from less than an hour to at most a few days. If he is undisturbed by rivals, the tending male simply follows the female until she signals her intent to mate by stopping; at this point, the male mounts and copulates. Since no one has ever documented copulation between humpback whales, however, any equating of escorting and tending must remain tentative.

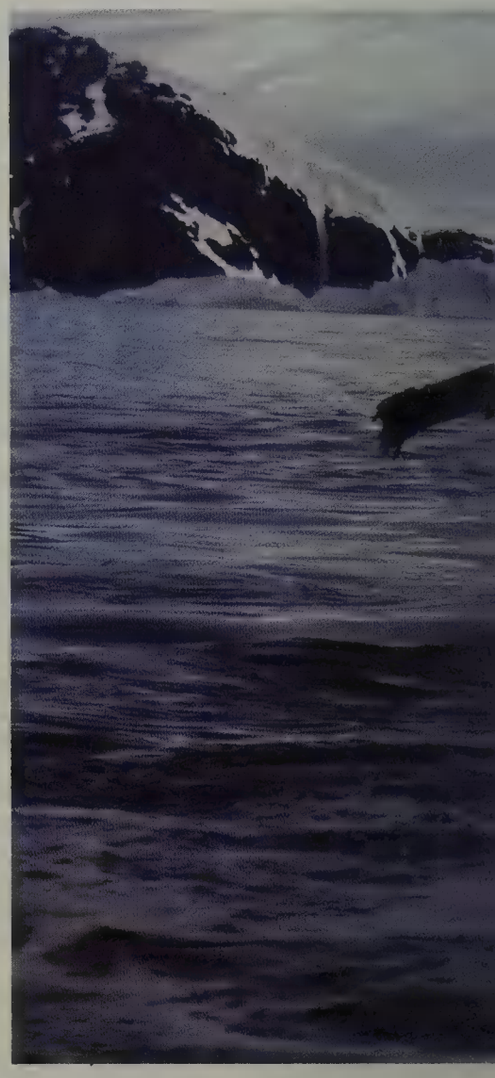
The absence of documented matings between humpback whales is disappointing but not inexplicable. The whales are usually visible at the surface for only a few minutes out of each hour. Underwater observations of whales are limited by the speed and depth of the whale—it is impossible for a human diver to follow even a slow-moving whale for more than a few minutes. Considering that copulation is very brief in many mammals, the apparent modesty of humpback whales is really not too surprising.

We do have a good idea of when mating takes place. In a few cases, we have documented that a female accompanied by males one winter was back with a calf the next. Since humpback whale gestation is eleven to twelve months, mating must have occurred sometime near the period that the female was associated with the males. For example, on March 2, 1981, we spotted a female humpback near the island of Maui, accompanied by a single male. We next sighted her a month later near the island of Kauai, 240 miles away. At this time she was leading a surface-active pod, which included five other adults aggressively competing to get near her. She returned to Maui the next year, accompanied by a newborn calf.

Not only are the associations between cow-calf pairs and escorts transitory but the whole structure of humpback whale pods in Hawaii is very fluid. Joseph Mobley, who worked with us there, found pods gain or lose a member about once every seven hours. Larger pods tend to gain and lose members more rapidly than smaller ones. Likewise, we have sighted and identified whales extensively, but we have rarely seen the same two whales to-

Breaching, in which whales hurl themselves vertically out of the water and land with a thunderous crash, can be aggressive, but whales also breach in seemingly amicable situations. For example, humpback whales may breach when they meet up or separate on the feeding grounds, and young humpbacks may breach as a form of play. Thus a breach, such as the one below, may have different meanings in different contexts.

John Dominis: Wheeler Pictures



gether twice on the breeding grounds.

In the past, commercial whalers and whaling biologists believed that all baleen whales formed monogamous pairs or small family groups. But this assumption was based upon the sexual composition of a few groups of whales that had been killed. Our observations of pod structure and aggressive competition between males now suggest quite a different mating system for humpbacks. Sighting histories of individual whales show that during a single winter, females are seen both serially and simultaneously with many males, whereas males are seen serially, but not simultaneously, with many females. This pattern indicates that humpback whales are either polygynous or promiscuous. In a polygynous mating system, males attempt to mate with many females but females usually mate with a single male. In a promiscuous system, both females and males may mate with several individuals. Until we are able to document copulation between identified whales, we cannot determine which of these two mating systems accurately describes humpback behavior.

As the whales arrive in southeastern Alaska during late spring and early summer, serious attention turns from mating to feeding. Humpback whales will feed on prey ranging from half-inch-long euphausiids, or krill (a planktonic crustacean), to fish ten inches long. Social organization during feeding is strongly influenced by the varying sizes and types of prey. We have found at least two distinct feeding patterns—fluid associations between individuals feeding on swarming euphausiids, and stable associations among individuals feeding on schooling fish.

Early in the summer, when euphausiids are scarce, most humpback whales are solitary or form small pods. As euphausiids begin to swarm and concentrate during late summer and early fall, up to forty whales may aggregate in areas only a mile in diameter. Early whalers referred to these groups as shoals. Within these shoals, whales casually join and leave smaller pods of four or fewer members.

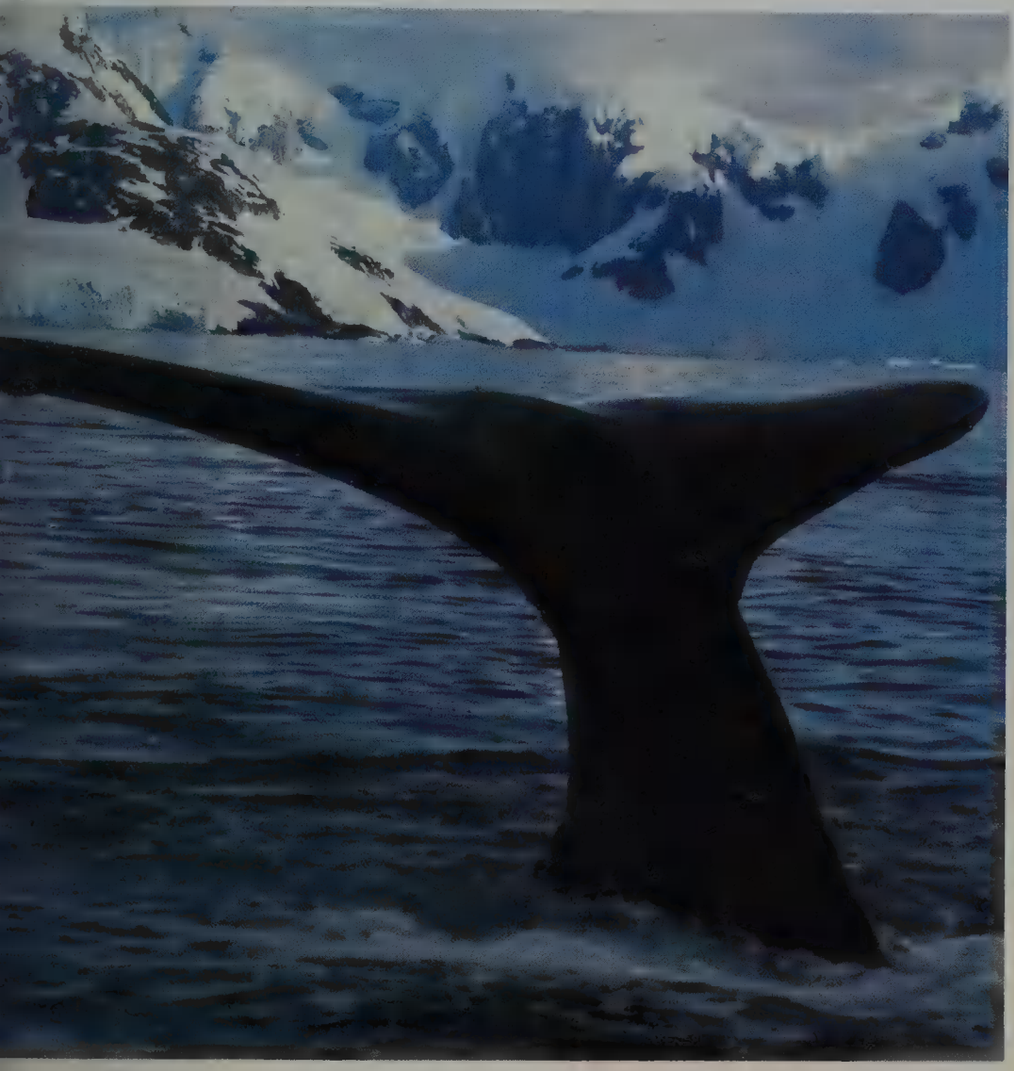
Although both feeding groups and mating groups are fluid in terms of individual membership, their sexual composition and behavior differ markedly. There are no rigid rules for associations between the sexes in southeastern Alaska, for example. Feeding groups may be all males, all females, or males and females. And cow-calf pairs are generally solitary. When they do spend time with other whales, the others can be of either sex.

Most striking to us is that humpback whales show little evidence of aggressior or competition on the feeding grounds. In stead, they appear to be quite tolerant o each other. They may even engage in co operative strategies such as echelon feed ing. As first described by biologist Charle Jurasz, echelon feeding involves two t four whales lunge feeding in close syn chrony. During each lunge, the whales ar parallel to each other, separated by half body length. The echelon formation re quires loosely coordinated movements an presumably increases the feeding effi ciency of the individuals involved.

But humpback cooperation can go fa beyond this casual level. For the past fou years we have observed a cohesive grou of six whales that establishes a seasona home range in Icy Strait, just outside Gla cier Bay National Park. In 1981 we wer able to observe the group on only one da

The huge tail fluke of a Southern Hemisphere humpback whale disappears into waters near Antarctica. The southern population of humpbacks feeds in icy antarctic waters and breeds in the warmer oceans to the north.

Douglas T. Cheeseman, Jr.; Peter Arnold, Inc.



but we know that the six whales remained together during the summers of 1982 and 1983. Studies conducted by Ken Krieger and Bruce Wing, of the Auke Bay Laboratory of the National Marine Fisheries Service, show that these whales were feeding primarily on schools of herring at a depth of 60 to 140 feet.

Admission to the Icy Strait group appears to be affected by an animal's sex and reproductive stage. From our own data, as well as earlier observations by Jurasz, we believe that five of these whales are mature females. We have not yet determined the sex of the sixth member. In the years that any member was accompanied by a calf, she did not join the group. In 1984 several of the members returned to southeastern Alaska with calves, and the group did not form at all. The remaining members without calves did not associate with other whales. This summer (1985), five of the six whales returned to Icy Strait without a calf. These five whales have rejoined and are feeding together with the same esprit de corps.

While the Icy Strait feeding group tends to remain together in a small home range, other feeding groups travel together like a pack of wolves or a pod of killer whales. On July 17, 1981, in Frederick Sound, we saw eight to ten whales diving and lunging together as a group through the center of a single bubble net nearly seventy-five feet in diameter. This coordinated feeding behavior was similar to what Jan and John Straley observed in their study of late-season whales in nearby Seymour Canal (see "Whales at Table," by James W. Greenough, *Natural History*, December 1981). As the whales lunged simultaneously through the surface, we could see herring leaping out of the water in an unsuccessful attempt to avoid their gaping jaws. Three days later we found the group feeding in the same location. Then, two months later, we found them lunge feeding in Chatham Strait, more than eighty-five miles away. In 1984 we again found roughly the same feeding group in three different areas of southeastern Alaska. Photographs show that many of the same whales were in all six of these groups. Adult females seemed to predominate among the regulars in these groups, but males were also present. To our knowledge, this is one of the most remarkable records of social stability and coordinated movement among baleen whales.

The group's method of feeding was also intriguing. By monitoring underwater sounds, we found that one or two whales would give a series of trumpetlike calls as the group was ascending to the surface. These calls were rhythmic and lasted about forty-five seconds, rising in pitch near the end. We recorded them in 1981 and 1984 and found they were identical. In general, humpback vocalizations on the feeding ground are sporadic and are not as long and complicated as the better-known "song" from the mating grounds. Given the circumstances, we believe the feeding calls have one of three possible functions. They either help synchronize the whales in their surfacings, help the caller to maintain social dominance over the group, or serve to disorient the schools of fish the group is preying on.

Why do humpbacks bother to feed on elusive schooling fish when slow-swimming euphausiids are easier to catch? Swarming euphausiids may not be readily available each season or during all times of the season. The recent studies of Wing and Krieger show that the abundance and distribution of whale prey vary significantly. We have also found that the nutritional value of some schooling fish may be far superior to that of euphausiids—herring, for example, may provide 50 percent more calories in equal volumes. This is an attractive benefit for an animal with only a few months to gather its food for the entire year. Like the pack-hunting strategy of social carnivores, cooperative feeding

C. Scott Baker

The return of the whales from Hawaii to the waters of southeast Alaska marks the end of hostilities. The humpbacks begin to fraternize again. Early in the summer they may form small pods, below, that feed on krill, a planktonic crustacean. A little later, when schools of fish appear, the whales may band together in larger, more stable groups. These cliques sometimes remain together the entire summer. Right: A vertical club of humpbacks gorge on herring in a synchronized lunge-feeding maneuver.

William Stifel, Kewalo Basin Marine Mammal Laboratory

may allow humpback whales to exploit a rich source of energy unavailable to solitary feeders.

While migration has a profound influence on seasonal changes in the social behavior of humpbacks, the basic social requirements of whales may in turn determine the pattern of migration. By comparing identification photographs collected by researchers working in other regions, we have begun to trace the movement of humpback whales throughout the central and eastern North Pacific. The results, so far, suggest that North Pacific humpback whales form a structured stock, a series of geographically isolated feeding herds that may include groups of related whales. The waters of southeastern Alaska, for example, seem to support one such feeding herd that is segregated from others to the west. Whales from southeastern Alaska assemble with other feeding herds on the Hawaiian wintering grounds to form a large breeding group. From photographs taken by biologist William Lawton, we also know that some whales from southeastern Alaska migrate to a second wintering ground near the Baja California peninsula of Mexico. Research by Jim Darling and Charles Jurasz has shown that some individuals may go to Hawaii one year and to Mexico in another. What all of this implies is that the humpbacks have evolved a strategy of feeding cooperatively with relatives and competing with strangers for breeding partners—and this may explain their pattern of migration.

We hope to expand our study to include the feeding and breeding grounds of humpback whales along the Asian coast of the North Pacific. Humpback whales in this region were intensively hunted by shore-based whalers until the early 1960s. But now almost nothing is known about their distribution or numbers. Early whalers believed that these whales formed an "Asian stock," which remained isolated from an "American stock" in the eastern North Pacific. But it also seems possible that humpback whales throughout the North Pacific form a single structured stock, with whales from several feeding herds traveling to any of the three breeding grounds—Mexico, Hawaii, or Asia.

After ten years, we are just beginning to form a picture of humpback whale behavior and migration in the eastern and central North Pacific. But when one is studying an animal with a life span of possibly forty years or more, ten years can only be a beginning. By following the life histories of individual whales, we can continue exploring for decades the role of competition and cooperation in this species. □

The Promise.

Renault Alliance's European technology will give you superior room, riding comfort and driving ease

The Proof.

100 new car shoppers compared Renault Alliance to Toyota Corolla, 76 chose Renault superior overall.

	Comfort/ Convenience	Riding Comfort	Driving Ease	Styling Interior	Styling Exterior	Overall Superiority
Renault Alliance	85	82	70	89	72	76
Toyota Corolla	15	18	30	11	28	24

ationwide Consumer Testing nstitute asked new car shoppers[1] o compare Toyota Corolla Dlx ith 1.6 litre to Renault Alliance L with 1.7 litre in 30 categories, ncluding room, riding comfort nd driving ease. he results: 76% of ne shoppers voted lliance superior verall, winning 29 out of 30 ategories. But there's more. The 986 Alliance has improved ileage ratings,[2] **41** MPG HWY, 5 MPG CITY. Redesigned and nproved struts, sway bars and nocks for a smooth ride. And merica's best small car protec- on—5 years or 50,000 miles, lus free required maintenance, parts and labor; you pay only for fluids.[3] All this European technology in the Alliance DL (shown) for **$7245.*** Now available with Accusound by Jensen, a premium 6-speaker system. 2-door prices start at only **$5895.*** Renault Alliance. **Built in America.** See your Renault dealer for test details. Then drive an Alliance for yourself. Because if you're like the small car shoppers we know, your preference for European technology will prove our promise.

Nicknamed petticoat palms because of the skirts of dead leaves that hang around their trunks, fan palms are the largest native palm trees of the continental United States.
David Muench

Reading the Fan Palms

We know where these trees grow, but we're not sure how they got there

by James W. Cornett

The Colorado Desert—which reaches from the edge of Arizona into southeastern California and down into Baja California—is an arid, low-lying region of shifting sand dunes and stony flats. In July the temperature often rises above 110 degrees Fahrenheit, and the average annual rainfall barely reaches three inches. It is one of the last places on the North American continent where one might expect to find verdant groves of palm trees, yet desert fan palms (*Washingtonia filifera*) do exist here. The trees thrive near the occasional stream, spring, or seep, sometimes growing to seventy-six feet in height and forty inches in width. Their stout trunks are typically shrouded by ground-length skirts of dead fronds, but sometimes those coverings have been burned away. This species is the only endemic palm in the western United States and the most massive in all of North America.

These palm oases—"tropical islands" tucked away in such remote places as Lost Palms Canyon, Hidden Spring, and Surprise Canyon—had piqued my curiosity for two decades. I wondered how the palms had become established in such out-of-the-way sites. Were the trees ancient residents or new arrivals? And what determined the size and vitality of the groves? How did they spread from one distant spring to another, if indeed they did? With the aid of a grant from the R.K. Mellon Foundation, my co-workers at the Palm Springs Desert Museum in California and I were able to embark on a three-year search for answers to these questions.

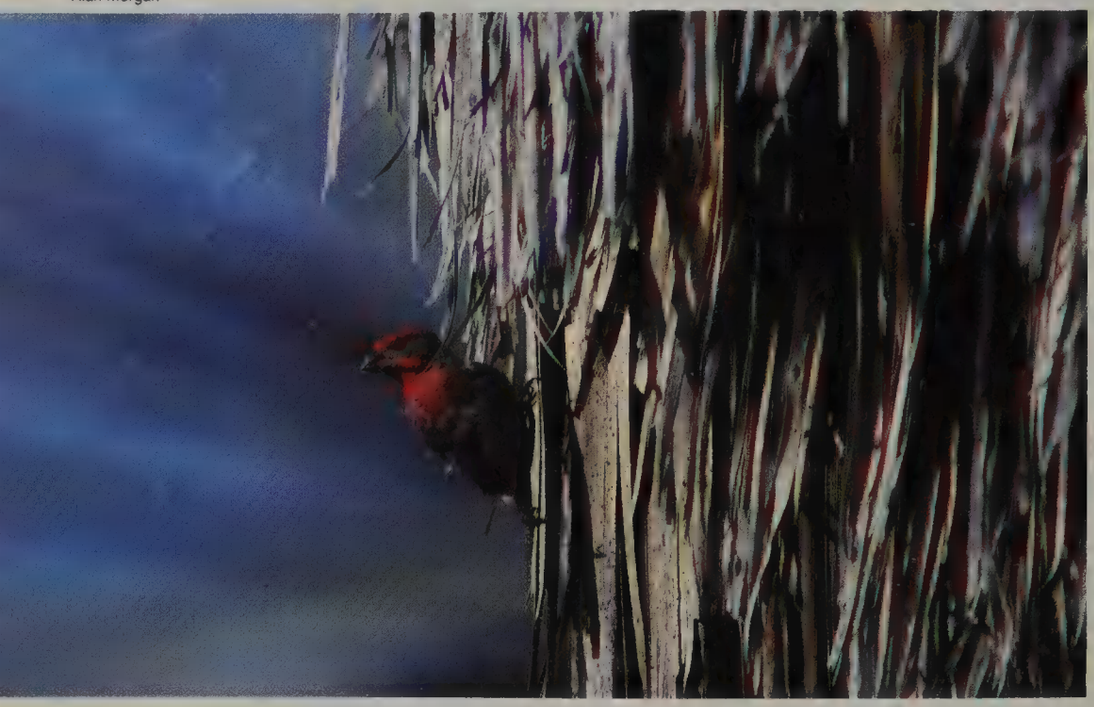
The desert can be a lonely place in which to conduct ecological studies, but to our delight, we were seldom alone in an oasis. These verdant outposts attract an abundance of birds, which come to feed, drink, and rest among the palms. More than eighty avian species use these "pit stops" on their migratory journeys. Some of our more startling sightings included snow geese coming down their flyway on the way from Canada to the Salton Sea, as well as American avocets and belted kingfishers. Nearly two dozen other bird species are known to nest in the oases, and for most of them there are no other satisfactory nesting sites for miles around. Mourning doves, owls, roadrunners, and house finches frequently rear their young in the thick skirts of the palm trees. Brightly colored hooded orioles use palm leaf fibers for their basketlike nests, which they attach to the underside of a palm leaf.

Oases also attract many kinds of mammals. Where there are palms, there is often drinking water nearby, and the trees' great height—the equivalent of a six- or seven-story building—can serve as a distant visual signal to birds, coyotes, and bighorn sheep. Rams and ewes are occasionally seen near the oases, and their droppings are regularly observed. The western yellow bat, as far as is known, is restricted to the vicinity of palm oases where it roosts under the trees' skirts during daylight hours. The ubiquitous raccoon, although not really a desert animal, has been able to disperse into the largest of these remote sites. In several cases the raccoons must have crossed miles of inhospitable desert and then become trapped in the islandlike environment of an oasis. Coyotes are the most conspicuous large mammals drawn to palm oases. Because they gorge themselves on the palm fruits, they visit every grove, even those where drinking water is not available.

Healthy, mature fan palms produce up to half a million fruits each fall. These pea-sized dates possess a sweet-tasting flesh, similar to that of commercially marketed dates. Unfortunately for humans, the seed occupies most of the fruit and is rock-hard.

The house finch is one of at least eighty bird species sighted in fan palm oases. It often nests and rears its offspring in the trees' leaf skirts.

Alan Morgan



That makes the fruit nearly impossible to eat. Two migratory species—western bluebirds and cedar waxwings—feed extensively on the rind but consistently discard the seeds. In the laboratory, cactus mice and antelope ground squirrels also eat the rind but only consume the seeds if the alternative is starvation. Only the spiny pocket mouse eats the entire fruit, yet even this species loses weight on a diet of nothing but palm fruits and would probably die without supplementary foods.

Coyotes digest only the flesh of the date and pass the intact seeds in their droppings. In the late fall and winter, when the palms are in fruit, coyote droppings may contain hundreds of palm seeds. We were surprised to learn that not only did these seeds germinate after their intestinal travels but they also did so in less time and with twice the success of unconsumed seeds. Coyotes are also known to travel up to thirty-six miles in three days, probably the maximum time that palm seeds can remain in the digestive tract of a healthy animal. Thus coyotes may be the most important dispersal agents of the palms' seeds and could have transported them to almost all of the known fan palm sites. The only three exceptions are a group of five trees at Mopah Spring in California's Turtle Mountains and oases in the Kofa Mountains and at Castle Creek, both in the Sonoran Desert of Arizona. These three sites have had palms for as long as anybody can remember, and each is more than seventy miles from the next nearest palm oasis, too far for coyote dispersal. Since the seeds are too heavy to be transported by the wind, how did these isolated groves come into being?

One explanation for their existence is that they are relict populations, left over from a time when palms were more abundant and more widely distributed. Fifty million years ago, during the Tertiary period, the climate in western North America was warmer and more humid than it is now. Springs, streams, and lakes were relatively common and provided the large quantities of water required by palms. Palm fossils indicate that these conditions were widespread and existed as far north as Alaska. Much later, during the Pleistocene epoch, about two million years ago, increasing aridity and periods of cooler temperatures forced the palms, as well as many other types of subtropical vegetation, southward into what is now the Sonoran Desert. With the drying out of the Southwest since the Pleistocene, many, and ultimately most, of the springs and seeps disappeared. The result has been the restriction of palms to the few places

Cottonwoods have longer roots than fan palms and therefore have a competitive edge even where water collects, as in this region of Guadalupe Canyon in Baja California.
David Cavagnaro

where faults and fractures allow ground water to reach the surface and along streams that drain the mountain peaks forming the western edge of the Colorado Desert.

Are all palm oases, then, relict populations? In an attempt to answer this question, we searched for some clue that would help us determine whether a specific palm oasis was indeed a relict population or the result of a recent, possibly human introduction. Palms are almost impossible to date because they don't produce growth rings in their trunks. Even if we had encountered a very old tree, we could not have assigned an age to it that might have placed it at a spring prior to Indian occupation or at least the very recent arrival of white settlers. Nor could we find any fossils near the sites of present-day oases. We had nearly given up trying to determine the question of origin when Kenneth Cooper, a retired biology professor from the University of California, suggested that the answer might lie with the palm's only deadly parasite—the giant palm-boring beetle.

Almost without exception, mature fan palms possess one or more half-inch holes in their trunks. These are the exit burrows of the parasitic beetle known to entomologists as *Dinapate wrightii*. The larvae of these beetles spend up to six years feeding on the woody interior of a trunk (sometimes killing the tree) before pupating and chewing their way out. Upon emergence, males and females fly off to mate in the crown of a palm. We have found only three oases in which we saw no exit holes and where the palm borers did not exist. These were the three most isolated sites: Castle Creek, Kofa Palm Canyon, and Mopah Spring. If those groves had been around when palms had a continuous distribution, the beetles should have reached them. The absence of the beetles suggests these palm oases were not present during past geological epochs and therefore are not relict populations.

If their seeds were not dispersed by coyotes, how then did the palms reach these remote locations? The most likely explanation is that the seeds were purposefully brought in by humans. We know that

A fan palm oasis thrives in a desert area. Wherever palms grow, water, although not always seen, cannot be far away.

Peter Menzel

Undeterred by the spiky edges of a fan palm frond, a roadrunner eats a small lizard it has caught.

James W. Cornett

Native Americans often transported seeds from one place to another, as demonstrated by the spread of corn throughout the New World. The abundant potsherds, bedrock mortars, and rock carvings around palm oases indicate that in southern California, Indians did live in or near the oases, and other archeological and ethnographic evidence indicates that they ground the palm fruits into flour, made baskets from the palm leaf fibers, and covered their homes with palm fronds. It seems reasonable, therefore, to assume that the same Indians introduced the useful fan palm to new regions. Today's Cahuilla Indians, living in the Colorado Desert, have told us that their ancestors distributed fan palm seeds when they moved from one region to another.

Although the dispersal of seed is necessary for the spread of most plant species, Indians played an even more important role in palm oasis ecology. The Cahuilla of southern California regularly set fire to palm oases to clean debris from an oasis floor. (Most mature trees are rarely killed by fire since their vascular bundles are strewn throughout the trunk, but this is not true of conifers and such trees as oaks, which are prone to heat damage because they possess a vulnerable layer of cells, called a cambium, just beneath the bark.) The Indians also knew that burning increased fruit production and killed the beetle larvae gnawing at the tree's interior. Setting fires, probably under carefully managed conditions, not only enhanced the harvest of palm fruit but also favored the survival of the palms by eliminating or reducing competitor tree species that are less tolerant of heat.

When my co-workers and I began our research on the ecology of desert fan palm oases in 1981, we knew that many oases had been named at the turn of the century for the number of palms they contained—for example, Una Palma, Dos Palmas, Five Palms, Twelve Apostles, Seventeen Palms, and Twenty-nine Palms. But when we visited those sites between 1981 and 1984, the names did not jibe with our counts. Una Palma had 3 trees, Dos Palmas had 308, the Twelve Apostles had vanished, and Seventeen Palms was more like the Twenty-nine Palms site, which had 36 trees. At first, we did not know how to interpret our count. Two earlier palm researchers had outlined a bleak picture, stating that palm oases were "being disturbed or destroyed by urban development and a reduction of natural water supplies." We also knew of destruction caused by countless fires set by vandals, by the introduction of the invasive tama-

Hooded orioles build their basketlike nests out of the fibers of fan palm leaves. They attach the nests to the undersides of leaves high above the ground, where the young are safe from predators.

James W. Cornett

risk shrub, which crowds out other plants, and by the incursion of hikers and campers into many oases each weekend. But our preliminary results suggested that palm populations might nevertheless be growing rather than shrinking.

During our studies, we visited most of the palm oases within the natural range of *Washingtonia filifera*. Fortunately, the late Randall Henderson, editor and publisher of *Desert* magazine, had visited those oases decades before and had painstakingly counted the palms in nearly every oasis in the Southwest, describing their condition, their associated vegetation, and the location and amount of water. His articles, which appeared over a 25-year period, were the basis for our comparisons.

We were surprised by what we found. Palm numbers were increasing at a dramatic rate. Sixty-five percent of the 110 palm oases that Henderson had investigated now had more adult trees. In some cases the increases were staggering. Willis Palms, which had 370 trees in 1964, had grown to 612 individuals by 1983. Andreas Canyon, near Palm Springs, California, grew from 322 palms in 1935 to 1,157 in 1984, an increase of 259 percent in forty-nine years. In several instances new groups of palms had sprung up where none existed before. There were at least three new oases in the center of the Colorado Desert just east of the huge inland body of brackish water known as the Salton Sea, and we discovered two new oases in Anza-Borrego Desert State Park in the eastern half of San Diego County. Fan palms have spread into southern Nevada at Rogers and Moapa springs, now the most northerly sites of this species. Our estimates place the current population of wild fan palms at approximately 19,000 individuals, up 40 percent since 1945. What had been happening that could account for such an impressive increase in the numbers and distribution of this plant?

As already mentioned, we knew that Indians set fires to clean oases floors of debris and permit the harvesting of the palms' fruit. We learned that ten years after a fire, the fallen flower stalks, fronds, and trunks pile up again, making it difficult to walk through an oasis. Twenty years after a fire, the debris is so deep and unstable that walking through an oasis can actually be hazardous: one step on the end of an eight-foot flower stalk can result in a blow to the head that is akin to stepping on a hoe. (It took our team an embarrassing number of mishaps to learn this bit of palm lore.) In addition, rattlesnakes use the litter as shelter and we met up with these oasis inhabitants many times. It was

Despite the obvious aridity of this region of Anza-Borrego Desert State Park, a flourishing fan palm oasis has evolved in a shallow trough.

Willard Clay

Coyotes are among the large mammals attracted to fan palms. They feed on the trees' sweet, pea-sized fruit and pass the seeds in their feces. Because the seeds are still able to germinate, coyotes are deemed an important agent in the spread of palms to new oases.

John S. Flannery; Bruce Coleman, Inc.

Fifty years ago there were 322 palms in Andreas Canyon, near Palm Springs. By 1984, the oasis had 1,157 palms. Periods of above-average rainfall are largely responsible for this impressive increase.

David Muench

easy for us to understand why Indians burned oases, perhaps every ten years, certainly every twenty. But with the permanent departure of Indians from the vicinity of palm oases in the late nineteenth century, the pattern of burning was altered, and for fifty years fire was all but absent in the palm oases.

Henderson's articles and photographs indicate that from 1890 until 1940 the size of palm oases had either stabilized or decreased slightly. The absence of fire allowed the palm litter to accumulate to depths that inhibited the germination and growth of young palms. Photographs taken in the Colorado Desert by Stephen Willard, one of the West's first desert landscape photographers, in the 1930s show stands of adult trees with leaf skirts to the ground and few, if any, young palms. Cottonwoods and sycamores, co mon plant associates, appeared to crowding out the palms. The former ha longer, but less dense, root systems a probably had a competitive advanta over the palms throughout the long-ter drought that lasted from the 1920s 1939. Then, after World War II, palm o ses suddenly began expanding.

Two things set the stage for that expa sion. First, from 1939 through 1945, the was a twofold increase in precipitation southeastern California. This change w accompanied and followed by an increa in the frequency of wildfires. (The i crease resulted from the buildup a accumulation of vegetation, which act as fuel, and the influx of settlers into t Southwest. Most palm oases fires a started by people.) The sudden loss transpiring plants after a fire also result in an increase of water flow at the surfac Palm seeds sprout like weeds when sca tered over moist, barren soil and, in ge eral, those were the prevailing conditio in many oases in the 1940s. Although thirty-year drought began in 1946, ma young palms were already established that time. Today, the postwar boom ca be seen as a distinct generation of thirt to forty-foot trees and accounts for th large increases observed in our study.

In 1976 the rains returned with a ve geance to the same Colorado Desert r gion, and greater-than-normal annu rainfall persisted through 1983. Now new generation of young palms h emerged. A cyclic pattern of change the size of a tree population is not uniqu to fan palms; it is a common form of su vival of many organisms that live in r gions with extremes of rainfall. In desert it is the scarcity of water, more than an thing else, that limits the growth of pop lations and individuals. The success most desert species depends on their ab ity to expand their populations rapid during periods of above-average rainfa so that some individuals will be able to su vive the inevitable drought ahead. In th case of the desert fan palm, both wat and fire determine its success or failure maintaining a foothold in the remote oas of the Colorado Desert.

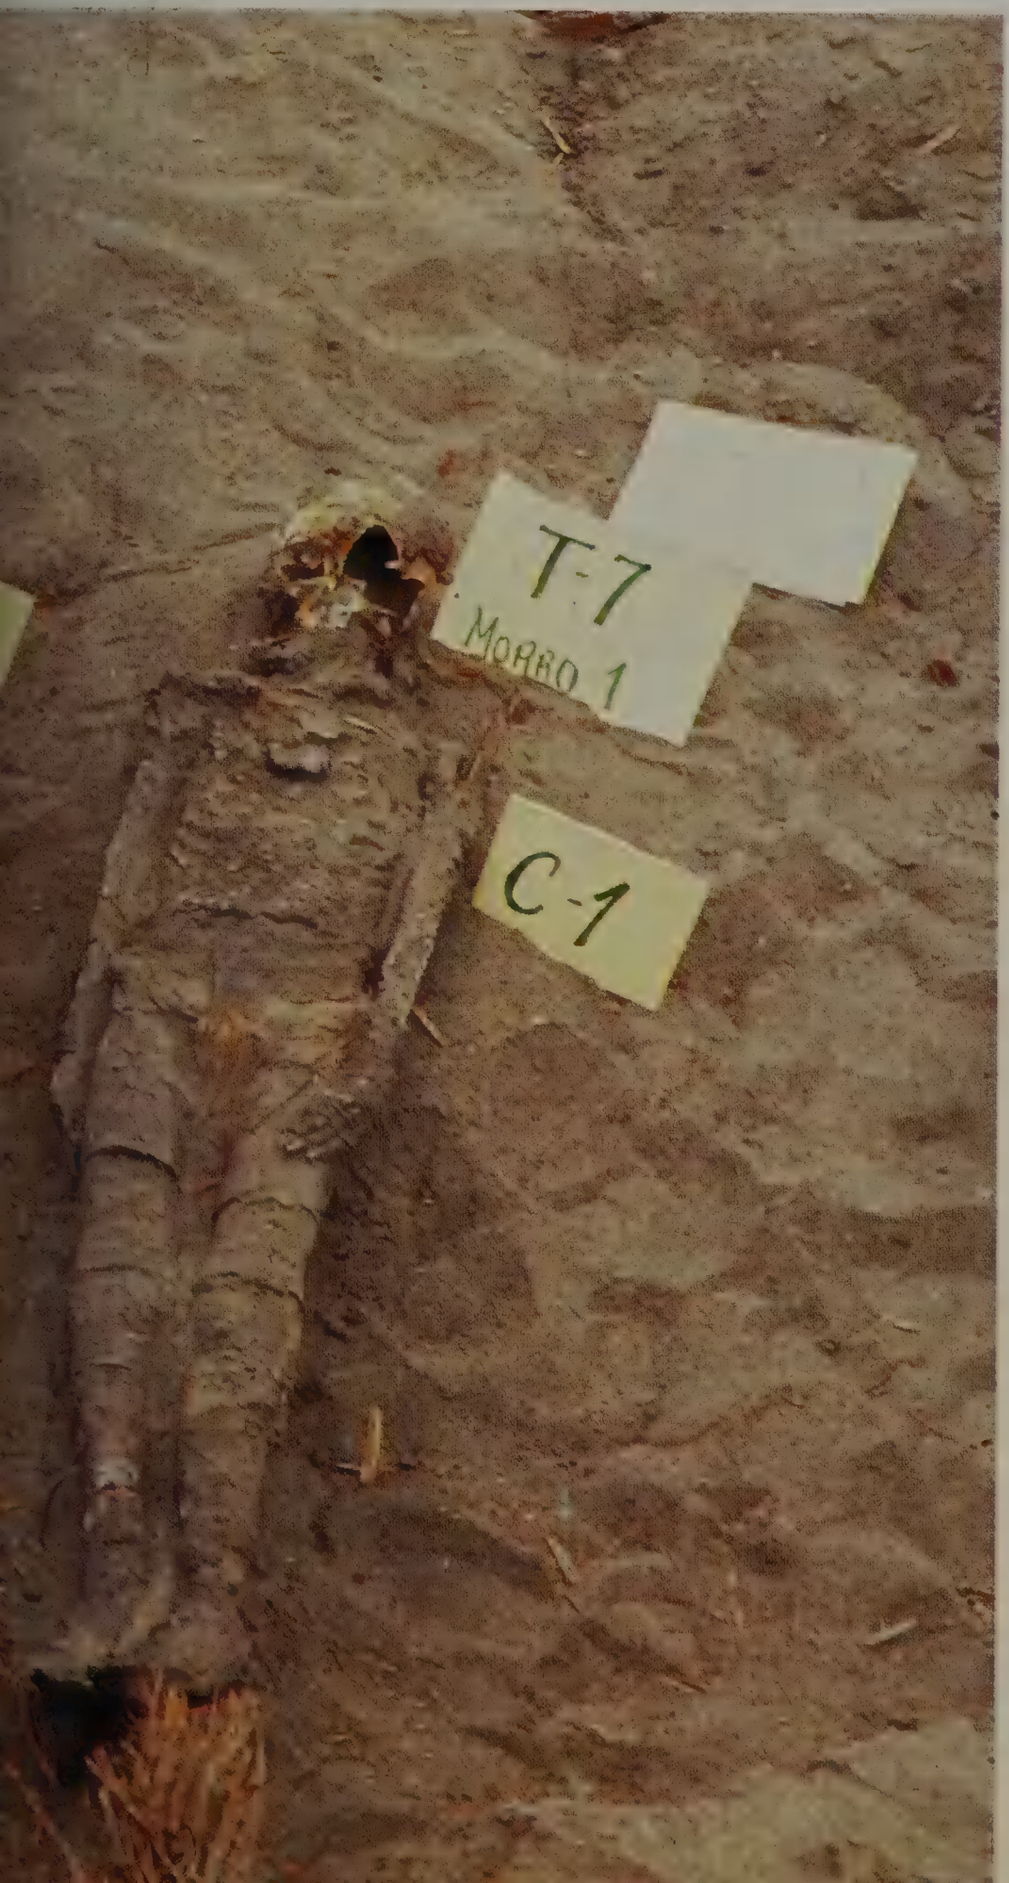
In 1983, workmen digging a trench for a new waterline in Arica, Chile, disturbed a pre-Columbian burial site. Archeologists who were summoned following the discovery salvaged nearly one hundred mummies, including this familylike group.

Marvin J. Allison

Chile's Ancient Mummies

More than 7,000 years ago, hunter-gatherers used elaborate techniques to preserve their dead

by Marvin J. Allison



Arica, Chile's northernmost port, thrives in defiance of the arid lands that surround it. The lifeline for the city and its more than 100,000 inhabitants is the San Juan River, a tiny line of fresh, sweet water that threads its way out of the Andean foothills and across some seventy-five miles of the world's driest desert to the Pacific Ocean.

A tall promontory, El Morro, looms above the southern edge of the city. Late in 1983, a ditch-digging machine was cutting a trench for a new waterline on El Morro's lower slopes when its blades began to churn up the legs and broken bodies of men, women, and children. The pipeline project had intruded into a pre-Columbian graveyard. Work stopped, an archeologist from Arica's University of Taracapá was called in, and a salvage operation was begun. In time, teams of archeologists and students uncovered the remains of 96 individuals, a most valuable addition to the growing collection of more than 1,500 mummies at the university's Museum of Archeology, where I and other investigators have been studying them for years.

With ever improving techniques of analysis and dating, these mummies, along with smaller collections at other institutions in Chile, are providing unprecedented insights into the early history of human disease, nutrition, and culture, including a practice of mummification more complex than the Egyptian process, even though it is two to three thousand years older. Our oldest specimens are, by far, the oldest-known mummies in the world.

Mummification can occur naturally, with the right environmental conditions, or artificially, when humans take steps to preserve a corpse. The conditions in northern Chile are excellent for natural mummification. Because the cold Humboldt current upwells off the coast, the warmer air collects little moisture from the Pacific Ocean. Thus, from the coast to the foothills of the Andes, it almost never rains. Years pass without rain, and in those rare years when some rain does fall, it is not heavy enough to penetrate a foot or more of soil. The absence of moisture—not just for years or centuries but for millennia—is

Lee Boltin

A pelican beak, below, was one of several contained in grave sites. Its sharpened end was an effective tool for skinning sea lions and also for removing the skins from human bodies to prepare them for mummification. The mummy of a male Indian, right, is well preserved after some 4,000 years of burial in arid soil.

Lee Boltin

the main reason for this unsurpassed collection of mummies.

Bodies discovered in an unmarked colonial graveyard about ten miles east of Arica at the Church of San Miguel illustrate the importance of aridity. The small church is next to an ancient Indian burial site where people have been interred—mostly without artificial mummification—for nearly 3,000 years. The corpses of the ancient Indians are dehydrated, but their bones are still firmly attached, their skin and hair still present. In contrast, the remains of the colonials, buried in front of the church, were mostly nothing but bones. We were puzzled by this difference until we discovered that attendants always sprinkled irrigation water around the church to keep down the dust. Moisture, penetrating the soil and the graves, had caused the corpses to deteriorate.

The burial practices of the ancient Indians probably helped preserve the corpses. Bodies were usually placed in shallow holes in seated, huddled positions, and then covered with cloth and reed mats. Under the strong sun, these grave sites were, in effect, solar ovens in which the corpse quickly dried out. In time, windblown sand drifted over the grave, further preserving the cadaver. And finally, the large amounts of salts, including nitrates, in the soil acted as natural preservatives.

In 1919, Max Uhle, the first archeologist to study these mummies, assumed that the natural mummies he found were the oldest and most primitive, while the elaborately prepared artificial mummies were more recent. Without the benefits of modern dating methods, he estimated the primitive mummies were about 2,000 years old. Uhle named these people the Chinchorro, or gill netters, recognizing their maritime location and fishing practices. We still use Uhle's name for these early Americans, as well as his classifications for mummy types, but carbon 14 dating has revealed two surprises.

First, the oldest Chinchorro are four times older than Uhle's estimate. Our oldest mummy has been dated at 7,810 years B.P. (before the present), plus or minus 180 years. Hans Niemeyer, who has excavated Chinchorro sites in the Camarones Valley sixty-five miles south of Arica, has obtained carbon dates of 7,420 B.P. and 7,000 B.P. With a series of carbon 14 dates, using material from the mummies, we now estimate the Chinchorro culture extended roughly from 7,800 to 3,800 B.P. The Chinchorro were probably closely related to another preceramic culture of the area, the Quiani (3,400 to 3,200 B.P.), and to the Faldas de Morro, a group with the

Chinchorro Mummy Sites in Northern Chile

Joe LeMonnier

first ceramics and metals in the area (2,800 B.P.). In short, in one small area we have found human and cultural remains that span a 5,000-year period. And some preliminary genetic and anthropometric studies indicate that all these people were closely related.

The second surprise from the dating was that the 7,800-year-old body, a man of about thirty-five years, was not a natural mummy but was instead an example of one of the most complex forms of mummification. This discovery raises all sorts of questions: Are there older mummies yet to be found? Where did the idea and the skills of mummification come from? How long have humans with complex cultures been in the Americas? These questions, and others, lead to interesting speculations; but since I am a paleopathologist, I spend my time studying the bodies and the artifacts found with them. The data they contain are fascinating enough for me.

The ninety-six bodies from El Morro, as indicated by carbon 14 dates, were interred over a period of more than 3,000 years. They represent all types of mummification, from simple air drying to the elaborate classic style. While there are many variations, all thirty-five classic mummies show the Chinchorro had techniques and a knowledge of anatomy that

Lee Boltin

Below: Two projectile points and a throwing stick, used to propel a spear, were removed from one grave site. Right: A fishnet fragment, found in a grave, is woven out of reeds.

Lee Boltin

contradict any notion that they were primitive, even though they had neither metal nor ceramics.

The first step for a classic mummification involved a careful incision in the cadaver and the removal of the internal organs, which deteriorate quickly. The skin and hair were cut away from the corpse, and major muscles were removed. The brain was removed through an opening cut in the skull or by hooking it out through the foramen magnum (the opening at the base of the skull). All this was done without metal knives. The embalmers used sharpened stones and shells and the sharpened beaks of pelicans. We have found a number of these beaks in grave sites. After 5,000 years they are still sharp, strong, and effective tools.

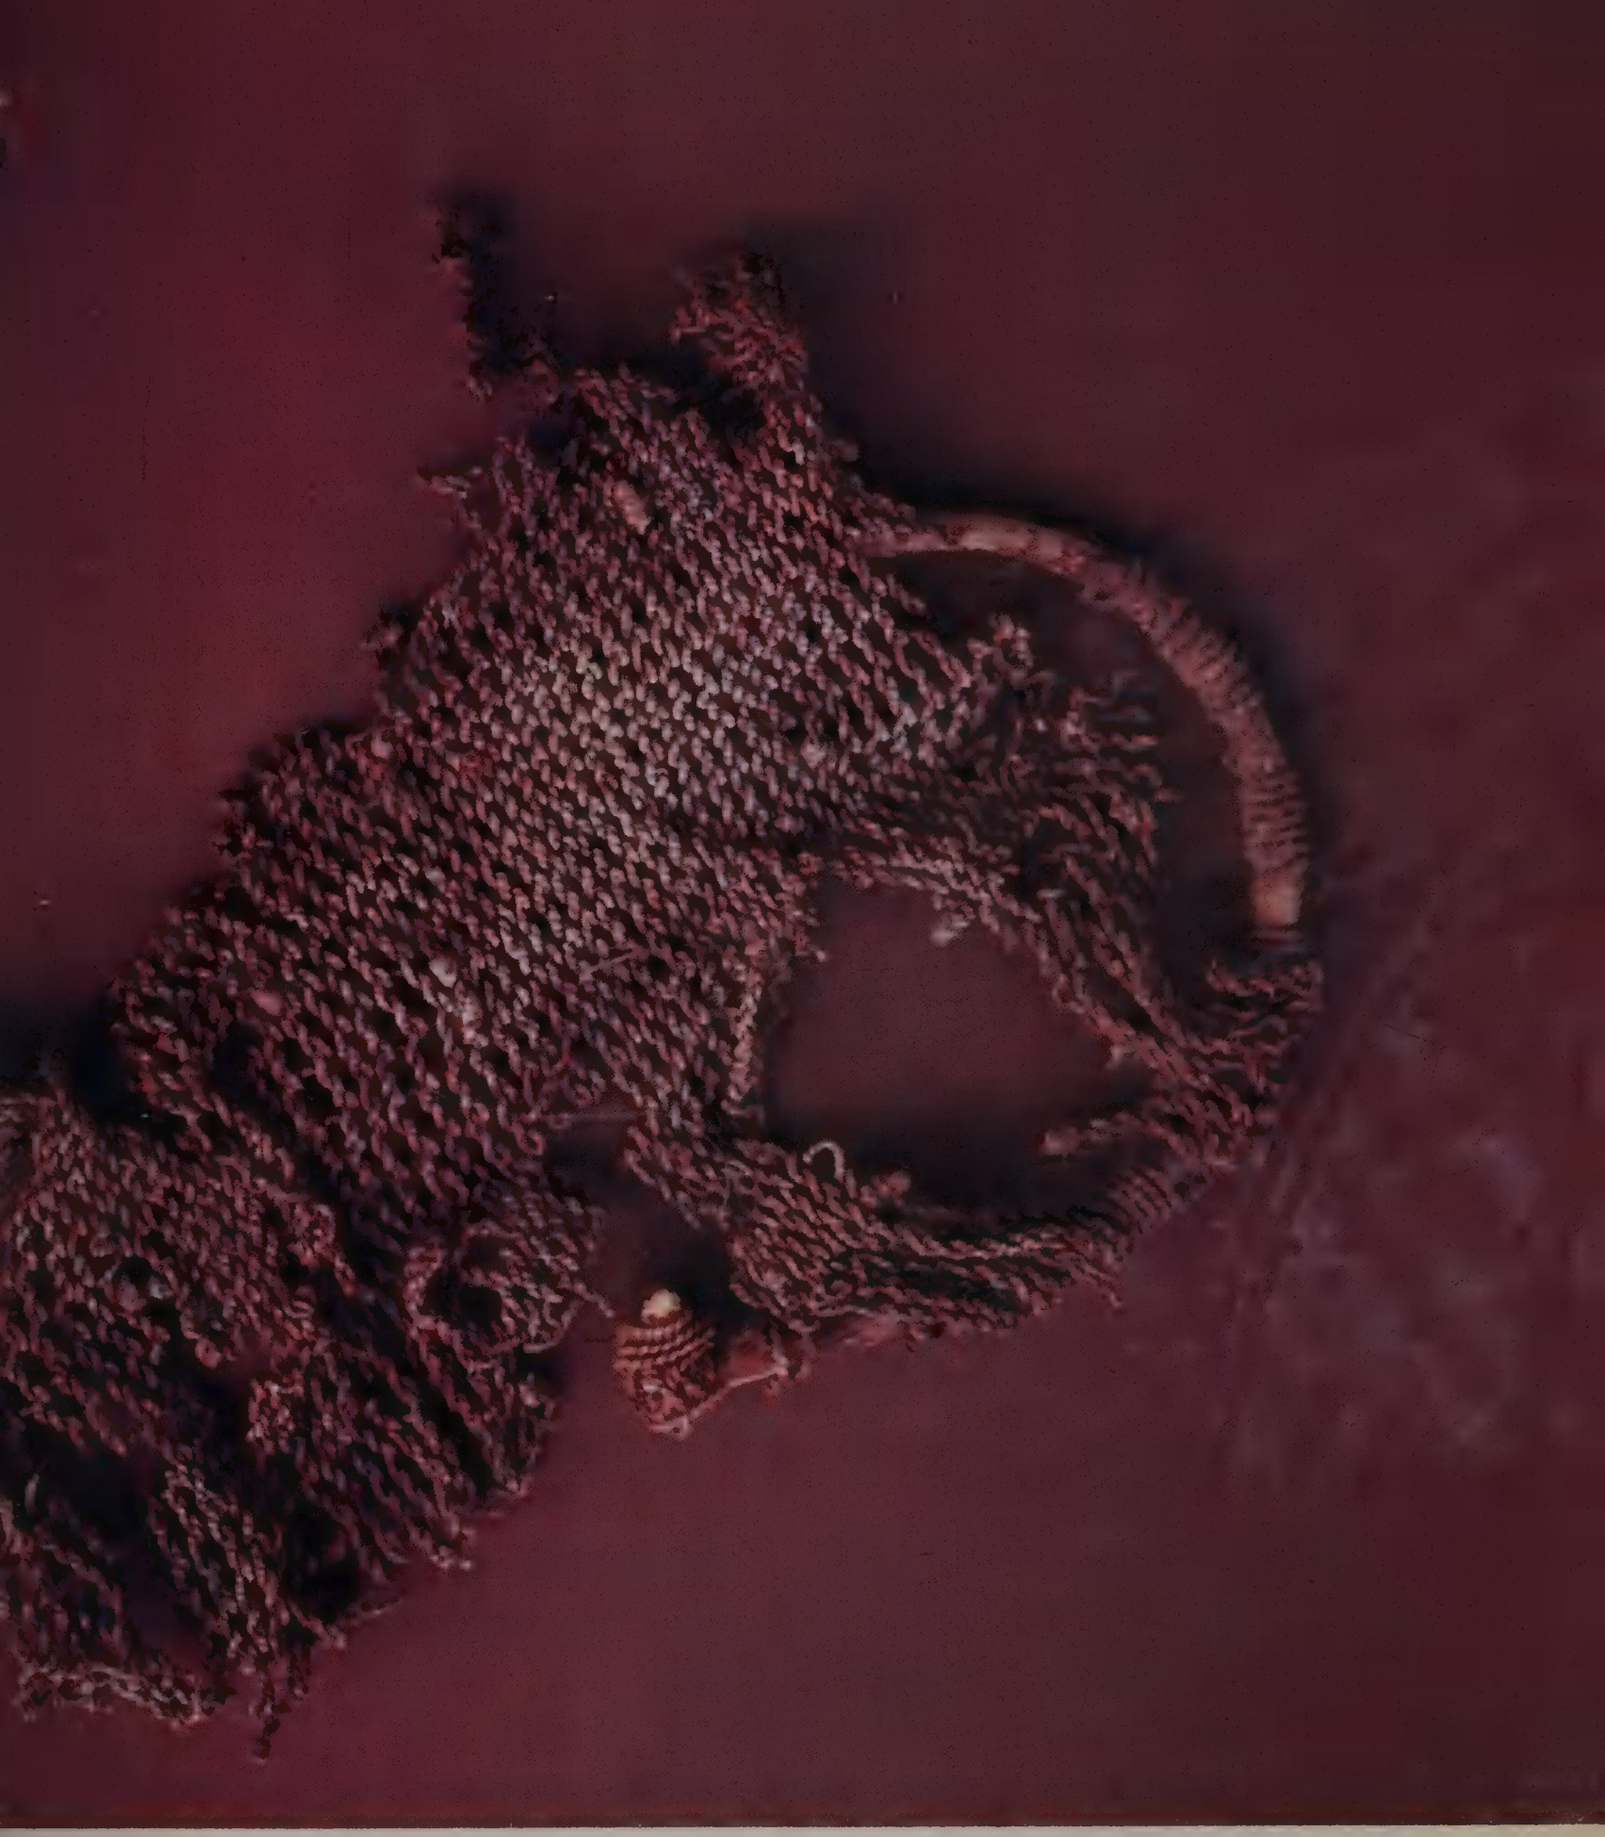
The body was quickly dried by filling it with hot coals and ashes. The skin and hair probably were soaked in salt water. Then the mummy makers—who were most likely specialists in the tribe—took a number of steps to make the corpse rigid. They rubbed the elbow and knee joints with abrasive stones until the bones were flat and then bound them together with fiber ropes. Another fiber rope ran down the arms and across the chest at the level of the collarbones to prevent the chest cavity from flopping open. They drove a sharpened stick under the flesh along the spinal column and tied the vertebrae to this stake. Two other sticks were inserted from each ankle to the skull.

When the body was rigid and dry, the mummy makers wrapped reed matting along the legs and arms, and across the shoulders. They filled the body cavity with wool, feathers, grass, shells, and earth. After binding the halves of the skull together with fiber cord, they wedged it on the ends of wooden poles at the neck and over the rope-bound vertebrae. To give the mummy a lifelike shape, the Indians molded clay over the limbs. Since the kneecaps had been discarded, the skin at the knees was cut and sewed tight.

The mummy makers sculpted a face mask of clay, with holes for the eyes and mouth. They tied the corpse's hair in bunches and bound it to the mask with rope. They painted the mummy black during some periods, red during others.

There were many minor variations from this procedure. Children were often simply eviscerated through an incision in the abdomen and filled with ashes and hot coals. Poles were tied to the legs or slipped under the skin. In other cases, skin on children was cut in strips and wrapped around their bodies like a bandage. With some mummies, the skins of other animals—often pelicans or sea lions—were used t
cover the bodies. In all cases, the idea wa
to make the body rigid and rebuild it t
lifelike dimensions.

When the mummy was finished, it wa
not buried. Apparently as some form o
ancestor worship, mummies were propped
up in groups and continued to inhabit th
community; perhaps in a spiritual sens
they helped to bring good hunting an



shing to their descendants. In return, the ving kept the dead in good condition, as dicated by the repairs on many mum- ies. Eventually, possibly when certain fluential people died, the older mum- ies were buried in small groups. Since any burial groups contained adults and ildren, perhaps the deceased were in- rred as a family.

We also found many plant and animal remains at the grave sites. These materials, along with the mummies and even the campsite dirt stuffed into the mummies, have provided us with many clues about the daily lives of the Chinchorro. The early Indians were hunters and gatherers, living mainly on products from the sea. They used sophisticated gill nets to catch fish off the beaches (a method still used by some Indians in the area today). They hunted sea birds and marine mammals, particularly the sea lion, which they speared with a barbed harpoon.

The Chinchorro did not practice agriculture, with the possible exception of growing reeds for mats and fiber. They used the products of their environment—pelican beaks and feathers, seashells, sea lion hides, and even whalebone—for practically all their needs. We have found

The small wooden mortar and pestle, below, was used for the preparation of narcotic substances, which the Indians may have used for ceremonial purposes. Opposite page: A wooden effigy placed in one grave may have had religious significance for its carvers.

Lee Boltin

some use of rhea skin and feathers and llama wool, which would indicate the coastal Chinchorro traded with the inhabitants of the Andean highlands.

The Chinchorro men suffered from one of the earliest known occupational diseases; one-quarter of them had a bony growth in the ear canal—probably the result of multiple ear infections—that would have led to deafness. Such growths are common in people who dive persistently for shellfish. Since none of the women had this lesion, they apparently did not go shellfishing. The women did, however, have "squatting facets" at the ankle–shinbone joint. These lesions occur when people work in a squatting position—in this case, probably opening shellfish. Nearly half the women had an arthritic degeneration of the neck vertebrae, probably from carrying heavy loads.

This division of labor, as well as the complex processes of mummification, means that individuals among the Chinchorro had specialized jobs and clear roles according to sex. This is unusual for such an early, small, and isolated group of humans. In later cultures, the practice of mummification degenerated, and judging from the hunting and fishing gear we find buried with both women and men, the roles of the sexes merged.

The origin of syphilis has fascinated medical investigators ever since a Barcelona physician, Rodrigo Ruiz de la Isla, reported a new disease brought back from America by some of Columbus's sailors. Throughout the Andean region, bone lesions that might be related to syphilis are found in human remains dating back at least 5,000 years. Bone lesions from a syphilislike disease appear in four of these early inhabitants of the north coast of Chile. We do not know if we are seeing evidence of the venereally transmitted disease syphilis or whether we are dealing with an early nonvenereal form such as yaws, or *pinta*. This will be difficult to answer until we find evidence of disease in the organs or skin.

Osteoporosis, a bone disease in which bone tissue becomes porous and fragile, is a widespread health problem for elderly women in industrialized nations. In virtually all individuals between the ages of forty and fifty, the skeletal mass begins to decline, but in women the rate is faster, possibly because of hormone deficiency. As such, osteoporosis is today's most common metabolic bone disease, but only in a small percentage of the population does it cause serious medical problems. Even so, in 1968 there were 700,000 fractures in women in the United States.

Among the Chinchorro, 31 percen the population had osteoporosis. All sufferers were women, and two-third them were under forty—a much youn involvement than in any other cultu The reasons for the prevalence of this b disease are not yet known. The patter childbearing, the workload, and diet probably all involved. Perhaps these vere cases can shed light on the problen elderly women today.

Because of my interest in patholog usually focus on diseases and causes death, but I do not want to give the pression that the Chinchorro were sic They appeared to eat a relatively high-p tein diet and to lead active, healthy liv As one of my younger associates not holding up a skull of a middle-aged m the mummy's teeth were in much bet condition than his own. In later cultur when irrigation agriculture came to valley, Indians ate more carbohydra and less protein. And the teeth of th later Indians have many more caviti Unlike the Chinchorro, their success knew the agony of a toothache.

For perhaps 15,000 years, if not long the western coast of South America hundreds of miles north and south Arica has been dominated by inhospita desert. Only a few isolated groups of In ans, clustered around rare sources of fre water, managed to eke out a living. their narrow niche, these Indians lived d ferently and apart from the major grou and Indian civilizations of the Ande highlands and the continental interi Some preliminary genetic surveys in cate these Indians were the direct desce dants of earlier tribes that lived in the gion for many thousands of years. Su continuity is without precedent anywhe else in the world.

And the arid conditions that so shap their lives also preserved them in dea As our techniques of analysis improve, will learn more about the daily lives a conditions of these obscure Indians th we know about any other group in preh tory. After nearly 8,000 years of silenc the Chinchorro are beginning to tell the story, and we have much to learn abo them—and ourselves.

Mount Magazine, Arkansas

Robert H. Mohlenbrock

t 2,823 feet, Mount Magazine is Ar-sas' highest mountain, towering above broad Arkansas Valley. Its size, isola-, and outline—which early French ters thought resembled a *magasin* n, or storehouse)—have attracted nat-ists to this day. The plateaulike sum-located in Ozark National Forest in southern Ozarks, is about seven miles , east to west, and less than one mile ss. Lining the north side of the moun-are sandstone cliffs that overlook ely wooded ravines more than one sand feet below. E.J. Palmer, a bota-from Harvard's Arnold Arboretum, mented in 1927, "Nowhere else in this sually picturesque part of America e I seen anything that approaches unt Magazine] for variety, beauty, fine views."

he north rim is dense with shagbark ory, red oak, chestnut oak, basswood, sugar maple. A trail from Cameron f, the most prominent cliff, leads over edge of the mountain to a broad ledge, bench, where some of the United es' largest specimens of black walnut, e oak, red oak, sour gum, and white are found. What lured me to the ntain for a visit in late May, however, a number of rare plants that live on e north-facing bluffs. I needed to take a few steps toward the rim from the ntaintop parking area at Brown ngs to notice a plant with purple flow-the Ozark spiderwort, one of four spi-vort species that have evolved in isola-in the ancient Ozark Mountains.

s I proceeded down toward the first ch, I passed two kinds of trees that the Fish and Wildlife Service is consider-isting as endangered species. One was Ozark chinquapin, a close relative of majestic American chestnut, which is rently affected by the same chestnut nt that has devastated most American tnuts in the country. The other tree, se foot-long clusters of flowers hung efully from slender branchlets, was the smooth-trunked yellowwood. The future of this member of the pea family is in jeopardy because of its susceptibility to wood-rotting fungi.

Two ferns growing along the shaded north face of the bluffs also attracted my attention. Hay-scented fern, with four-foot fronds, looks like a tropical species but is truly a plant of temperate climates. In Arkansas it is found only on Mount Magazine and one other cliff. A more unexpected find is the much smaller Rocky Mountain woodsia fern. Mount Magazine is the only place it grows between the Appalachian Mountains to the east and the Rockies to the west. The population in west-central Arkansas may be left over from ages ago when this delicate-looking fern had a more continuous range.

But the most enigmatic plant to me was the maple-leaved oak, a small, shrublike tree that I had wanted to see ever since I had learned of its existence a few years earlier. Palmer, who discovered this oak along the north rim of Mount Magazine in 1925, had never before encountered it, and it still has not been found anywhere else. Because some of the leaves of this oak reminded Palmer of the leaves of the sugar maple, he coined the common name maple-leaved oak. The choice of a scientific name was not so easy, however. Was the plant an oak species that had evolved only on Mount Magazine? A hybrid offspring of two other oak species that lived in the area? Or a form of another species that developed odd-looking leaves because of the local habitat?

Palmer wanted to describe the maple-leaved oak as a new species, and had he found it in similar habitats on other Arkansas or Missouri mountains, he probably would have done so in an instant. But he hesitated to because the tree grew only on one mountain, and it was an oak. Botanists name new species of hawthorn, blackberry, or milk vetch at the drop of a hat. But oaks have the reputation of being highly variable and even "promiscuous," when two different species cross to form a hybrid. A new oak is rarely named unless there is nearly irrefutable evidence of major physical distinctions, such as unique acorns. (The acorns of the maple-leaved oak, incidentally, are viable, unlike the seeds of most plant hybrids. The young

ORIENT & CHINA

In TRAVCOA'S Orient, you will live with Dyak villagers in Borneo, meet Torajas in the Celebes' and see ancient Burmese culture at Pagan and Mandalay. Discover Korean countryside and visit the hill tribes of Thailand.

TRAVCOA visits all of China's wonderful cities. Explore the excavations of Xian, the gorges on the Yangtze River Cruise, beautiful Guilin, the Stone Forest and Kunming. For the unusual, visit Tibet or Urumqi and Kashgar on China's Silk Route.

SOUTH PACIFIC

TRAVCOA's South Pacific includes the Australs, Western Samoa, and a cruise from New Guinea's Sepik River to the Trobriand Islands where colorful customs of a primitive culture survive today.

Tour Michener's Rurutu, Bora Bora and the Kingdom of Tonga. Travel from Sydney to Perth aboard the Trans-Australian Railway. Visit Tasmania, Fiji, the Maori country of New Zealand and see Fire Walkers in Rabaul.

SOUTH AMERICA

From Incan civilizations to Antarctica, TRAVCOA offers a surprising contrast of cultures, wildlife and exotic cities. Cruise the Amazon and Galapagos, explore Patagonia, and marvel at the giant statues on Easter Island. For an exciting expedition, live at a research station in Antarctica.

TRAVCOA's unusual Mexico offers ancient Mayan cultures of Chiapas and Palenque and the amazing sites of the Yucatan. Enjoy gala evenings and dine in the finest restaurants and cafes.

TRAVCOA tours are limited to 25 persons, with luxury facilities and a la carte dining.

plants they produce have leaves that resemble those of the adult plants.)

Palmer ruled out the possibility that the maple-leaved oak was a genetic freak because dozens of the plants lived on the rim of the mountain. He also found it difficult to imagine that any two of the other kinds of oaks then living on or near the mountain could have hybrid offspring with leaves like those of the maple-leaved oak. Palmer eventually decided, without experimental evidence, that he was dealing with an upland variant of the Shumard oak, a large tree found in the Arkansas Valley. He called it *Quercus shumardii* var. *acerifolia*, or the Shumard oak with maplelike leaves.

I do most of my botanical studies in southern Illinois, where the Shumard oak is a common forest tree. My first impression of the maple-leaved oak was that it had little in common with the Shumard. The habitat was wrong, the growth form was stunted, and the leaves, acorns, and buds were not really similar. Based on my own observations, I felt the maple-leaved oak was a distinct species.

There is one bit of research that can be done to try to unravel this oak's identity (and I am in the process of doing it). Nearly a decade ago, James Hardin and Paul Thomson, working independently at North Carolina State University and Southern Illinois University, respectively, discovered that each species of oak in eas ern North America has distinctive hai on its leaves. As seen through an electr microscope, some hairs are one-celle others multicellular; some are branche others unbranched; some are perched or pedestal-like stalk, others not. Interes ingly, a hybrid between two different oa has hairs from each of the parents. Wh the hairs on the leaves of the maple-leave oak are investigated with an electron m croscope, we should learn whether th match those of the Shumard or of a oaks in the area that might be the paren of a hybrid—or whether they are distin from all other oaks.

The vegetation and scenery of the nor face of Mount Magazine would be enoug to please most naturalists, but the mou tain offers more. Less than a mile awa across the flat summit, the south rim the mountain presents an entirely diffe

Mount Magazine's northern bluffs

t habitat. The arid conditions on the uthern face result in gnarled and unted trees. The post oaks that grow in e thin, parched, sandy soil are between 0 and 200 years old but stand less than ty feet tall, or two-thirds the normal ight. Where moisture is inadequate for ees, prairie grasses and wildflowers take er. The bluffs of the south rim are irreg-ar in outline and often form series of air-step ledges, where thick-stemmed ickly pear cactuses are able to survive oughty conditions by storing up large antities of water.

Near the western end of the flat-topped mmit, a scattering of wet pockets have en filled in by growths of sphagnum oss. These boggy depressions are ought to be left over from an ancient ne when the sea covered the entire area. s the ocean finally receded to its present sition, most of the coastal plain vegeta-n retreated with it. But the small bogs the summit of Mount Magazine have mained through the millennia, and sev-al of the plants that live there are coastal ain species. The yellow fringed orchid d the brilliant blue-flowered bottle gen-n are the most spectacular, but the rar-of all the plants on Mount Magazine is e inconspicuous dwarf pipewort, whose rrow, two-inch long leaves are barely ertopped by minute spherical gray wer clusters. Found only a half dozen nes, in western Arkansas, Oklahoma, d Texas, this flower is a candidate for deral listing as an endangered species.

Street Kids

by Brian Sutton-Smith

Children of the City paints a vivid picture of child life in American city streets between 1900 and 1920. Children are seen as laborers, hustlers, newsies, junkers, scavengers, and petty thieves, as "little mothers" watching over younger siblings, and as battlers for their own spending money. They are seen at play, and they are seen taking part in unions and strikes and defending themselves from the reformers who would coop them up in schools and playgrounds. More than sixty black-and-white photographs accompany the text and convey the atmosphere of the time with great power.

The descriptive material alone would have been sufficient for a book, but David Nasaw, who teaches history at City University of New York, injects a social and historical analysis as well. He contends that the early twentieth-century city was a city of immigrant strangers. Since most of its inhabitants had been born or raised elsewhere, only the children were really at home; and it was they who became the new Americans. They learned that if you could raise money, ever so little, leisure time could be a constant round of excitement. Unlike their rural forebears, who lived in a slower and less colorful world, these children were forced out into the street, with its crowds of children to play with as well as myriad spectacles and entertainments. There were subways, streetcars, skyscrapers, lobster palaces, vaudeville palaces, movie palaces, department stores, bridges, ferries, nickelodeons. It was these children, Nasaw argues, who grew up to become the consumer generation of subsequent American culture. They were the first to discover the purchase of goods and the purchase of leisure as a compensation for the miserable conditions of living and working. Put this way, what Nasaw gives us is only a rather dismal, and somewhat deterministic, story of the transformation of sober immigrants into leisure-hungry consumers.

But Nasaw has another and more romantic story to tell. It is about the sheer vitality of these city-street children, a vitality that transcends the miserable conditions of their lives, the overcrowding, the lack of privacy, the multistory tenements, the lack of ventilation, the stench from excrement, the darkness, the rats, the disease. Those "who portray the working-class immigrants as helpless, hopeless uprooted victims have misread the historical record. . . . The children of the city did not wither and die in the urban air but were able to carve out a social space of their own . . . the street made the children and the children made the street."

Literally hundreds of children played in the same side streets, and they formed quickly into gangs to protect their turf and their activities from other children, from adults, and in particular, from policemen. The cops were sworn enemies. Most of th

(University of Pennsylvania Press), and *Choosing Sides,* by Cary Goodman (Schocken)—probably because these works chronicle the efforts of the play theorists and reformers to save children from what were seen as the abominable conditions of their lives. As Nasaw says, "The reformers' first priority was to remove these children from the contaminating effect of life on the city streets." But *Children of the City* portrays the reformers as almost complete failures. Children valued their own turf too much to go to the clubs or playgrounds. They might have dropped in out of curiosity, but they would seldom stay. The figures for playground attendance then were about the same as those today; only about 5 percent of a child's playtime is spent at such places.

Interestingly, most modern academic play theory is derived more from what children do in nurseries, playrooms, laboratories, and clinics than from what goes on in their habitats in the countryside or on the city street. *Children of the City* challenges the relevance of play theory. What we learn in this book sounds more like the barnyard play of a Rabelais than it sounds like the play described by a Piaget or a Freud.

But Nasaw's book is mainly about the life of children as workers, not as players. Most working-class families of the day could not live on the income of the primary wage earner. Between 1900 and 1920, child labor kept working-class families solvent and together, even as children were being steadily driven out of the work force by immigrant adults and by child labor legislation. What did persist was afterschool work. Most of Nasaw's book is about the part-time selling of newspapers and shining of shoes by children until they were finally forced out of even this type of work by adults. But there were also flowers to sell, errands to be run (before telephones), and lace and candy to be peddled. If a child could mimic dialects or sing, customers were more likely to buy. Older children managed groups of younger hustlers who were cute enough to sell papers on their looks alone.

Hundreds of thousands of childen who grew up in America in the first decades of this century sold newspapers. Circulation managers fought with one another to build up their stocks of children. Some estimates are that as much as 15 percent of the ten- to thirteen-year-old age group of city boys were involved. And in the meantime, these children learned that morality didn't exist in the workplace. Their Horatio Alger stories involved deceit, the stealing of tips, shameless soliciting, hustling the supposed last paper, and begging for tips—all of which Nasaw sees as having been great "fun" for those involved.

Lewis Hine Collection, Library of Congr

Street gang, Springfield, Massachusetts, 1916

Many other children went into "junking" (salvaging) for wood, ice, iron, or coal on the railroad tracks, for old clothing, for furniture and machine parts, for bones, rags, bottles in alleys, for faucets and lead pipes in vacant houses, for overripe fruit, rotten meat, and other food at the produce markets. "American cities were the waste capitals of the world," writes Nasaw. Children collected junk like seagulls on the garbage dumps of the day. Junk was a necessary ingredient of survival.

The streets were usually regarded as off limits for girls, though not entirely so, for many girls were street traders along with their brothers. Legislation that regulated street trading often barred girls from th streets until sixteen years of age—boy were allowed on at ten—and elder siste were typically employed in raising your ger babies. Every increase in the mother workload (taking in washing, boarder homework for jobbers) meant an increas in the workload of young girls, but unlik their brothers, they did not get paid an therefore could not withhold or hide som of their earnings for their own personal en joyment. They could not experience th nickelodeons, the penny arcades, Bijou Pictoriums, and Theatoriums to anywher near the same extent that their brothe did. Commentators of the day noted tha lower-class children made up the majo part of the crowds in the cheap entertain

Lewis Hine Collection, Library of Congre

Child bootblack, New York City, 1910

nt centers. One of Nasaw's most inter-
ng chapters concerns the reformers'
uccessful attempts to get the police, or
one else, to enforce the legislation
ant to protect these children from such
ces and worse; from child abuse, seduc-
n, lewd posters, and white slavery. For
saw, the kids' "street smarts" were by
l large their best protection, and they
ded no more.

Finally, Nasaw describes the great
vsboy strikes, when boys sought to pro-
t their percentage of the sale and
ght efforts by big companies to in-
ase profits by lowering the margin. In
early years the boys won handily, but
r, as they were replaced by adult ven-
s and adult-controlled distribution sys-
ns, they were defeated.

All of this makes for an exciting story
l supports Nasaw's more general con-
sion that the period between 1900 and
20 was indeed a very special interval. It
rked the transition from the predomi-
ntly rural life of the prior century to a
urban one that was to increasingly con-
n children. Relics of rural pastimes sur-
ed along with emerging forms of com-
rcial stimulation and crowds of
ailable players, effective adult organi-
ion of all phases of a child's life was still
come.

Unfortunately (to this reviewer at
st), the author returns at the end of his
k to the broad and deterministic social
alyses with which he began:

FREE! Regular $12.75 Value!

RARE OLD U.S. MINT SILVER ½ DOLLARS

To gain new friends we are offering these beautifully circulated Solid Silver U.S. Walking Liberty Half-Dollars dated from 1916 to 1947 for the unheard of low price of only $9.95 each (an almost unheard-of saving on our regular catalog price of $12.75).

Leading experts and astute collectors consider these to be the finest examples of the engraver's art. So popular they've been hoarded for over 35 years. So valuable (over ⅓ ounce of pure silver in each) they've been melted down in the millions. No wonder they've disappeared from circulation!

Supplies limited—order yours today. SAVE MORE! FREE—order 6 and receive 1 FREE! SAVE EVEN MORE! order 13 and receive 3 FREE! (Our choice of dates.) Add $1.50 postage, insurance and handling per coin, $6.00 total on 6 or more coins. VISA and MASTERCARD orders accepted for $25.00 or more. If not delighted return within 14 days for full refund (less shipping charges). FREE with order: 32-page Guide, Catalog, Price Lists and complete information on U.S. Rare Coins as profitable investments. Orders filled first come, first served—this limited supply will not last long, so order *now*.

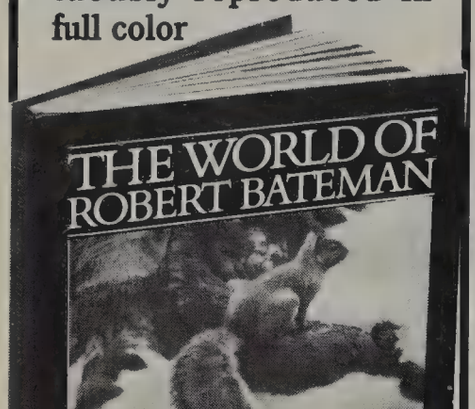
The magnificent wildlife painting of

Robert Bateman

An entirely new selection of his finest paintings —gathered and sumptuously reproduced in full color



In the year's outstanding art book—and the year's outstanding gift for naturalists—nearly one hundred of Robert Bateman's moving, richly detailed landscapes depict birds and mammals in their natural habitats ... from East Africa's big game animals to North America's coastal birds.

- Robert Bateman provides his own commentary, and the text is by Ramsay Derry
- Printed on collector's quality art paper, luxuriously bound in a lavish 11" x 11⅞" format

"If I could paint like another wildlife artist it would be Robert Bateman."

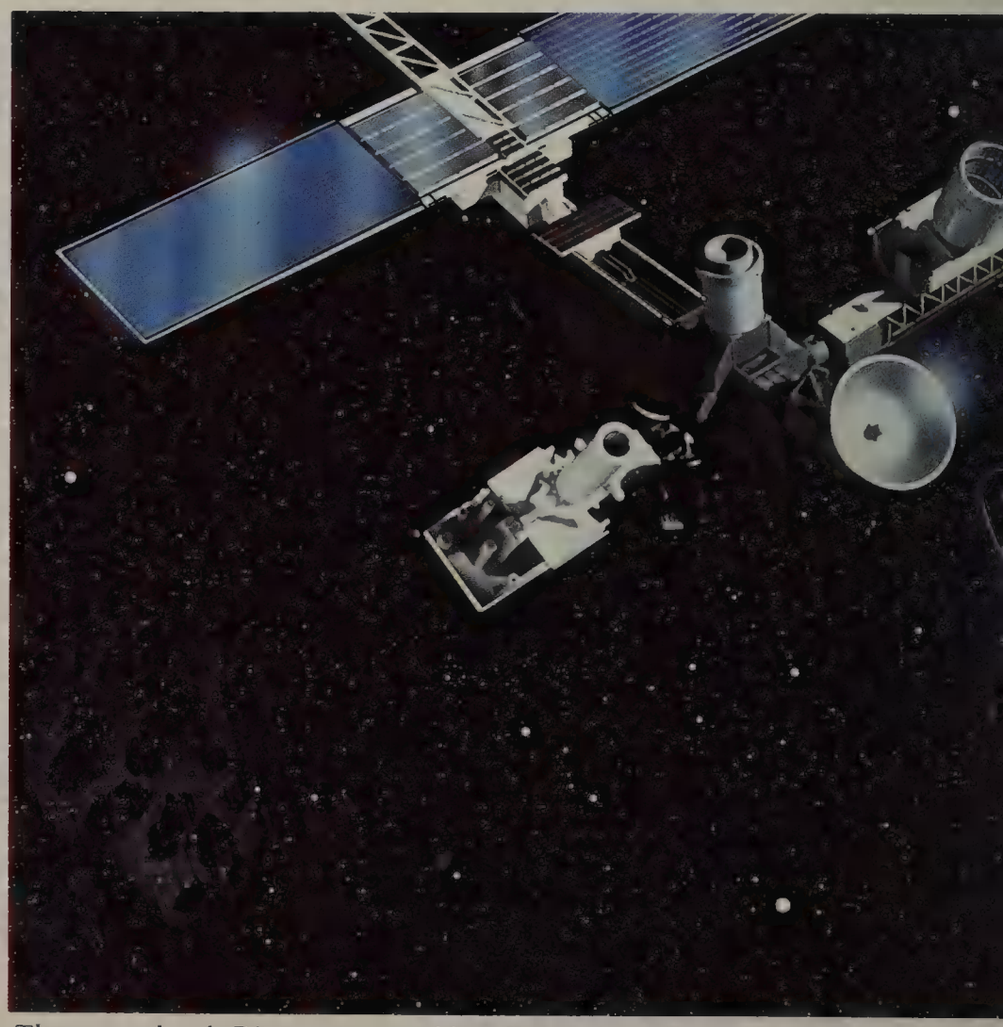
A Domeful of Stars

The original nineteenth-century plan for the American Museum of Natural History called for a soaring, Romanesque-revival tower rising from the center of the Museum's complex of buildings. The interior of this tower was to contain (appropriately enough) a vast Hall of the Heavens. But the great spire was never built, and it wasn't until 1935—some sixty years later—that the true "hall of the heavens" opened: the Hayden Planetarium.

An early article about the Planetarium described the spectacle presented by the first Zeiss projector. When the lights went down and the stars appeared, the commentator wrote, an "involuntary gasp" arose from the audience. The Zeiss projector, a marvel of German engineering, duplicated on the Planetarium dome thousands of stars exactly as they wou appear in the night sky. The illusion w nearly perfect. At the time, Planetariu Sky Shows consisted of a lecturer talki about the various stars, planets, and co stellations. The only "special effect" w the little flashlight pointer the lectu used to identify various stars.

Today, as the Planetarium celebrat its fiftieth anniversary, much of that h changed. Not only is the universe a mu vaster place than earlier thought, but it populated with complex phenomena such as black holes and exploding gala ies—that cannot be simulated with t Zeiss projector alone. And no longer can mere domeful of stars satisfy an audien raised on television and Lucasfilms' sp cial effects. Today, one recent Sky Sho



The space shuttle Discovery *assembling Star Lab, as depicted in a recent Sky Sho*

the Hayden Planetarium included the mulation of a supernova and expanding ebula, a glowing comet coma, rockets asting off, and a panoramic view of the rface of the sun with a vast solar flare cing across the sky. Images, sound, and ecial effects filled the Planetarium ome—which is forty-eight feet high, sev-nty-five feet in diameter—for the dura-on of the forty-minute show.

The creation of a modern Sky Show at he Hayden Planetarium takes several nonths and involves model building, art-ork, special photography, four comput-rs, sound and music synthesis, complex ptical effects, several hundred custom-uilt projectors, specially designed elec-onic circuitry, and, of course, the $2 mil-on Zeiss VI Star Projector—the sixth-

generation version of this remarkable machine.

Today, scripts narrated by Charlton Heston, Leonard Nimoy, William Shatner, and others have replaced the live lecturer. William A. Gutsch, Jr., the Planetarium's chairman, is a professional Sky Show writer (in addition to holding a Ph.D. in science education) and creates most of the scripts himself. "The shows are written," he says, "with special effects in mind. We want to create an environment in the dome. We're right there, floating in space. Or we're standing on the surface of Io next to a volcanic eruption. Or we're peering into a black hole."

The Planetarium is commemorating its fiftieth anniversary with Hayden: The Golden Years. *Narrated by Charlton Heston, this Sky Show looks at what we have learned about the universe over the last fifty years. The Planetarium is also presenting* Halley's Comet: Once in a Lifetime, *narrated by William Shatner. Both shows are offered as a double feature. For more information about the Planetarium call (212) 873-8828.*

Black holes and other exotic environments are created in the Planetarium's basement. When Gutsch has finished a

TRINIDAD & TOBAGO

Discover a world the world hasn't discovered.

In Trinidad & Tobago, you can have a bird in the hand, two in the bush, and a Picoplat in a zaboca pear tree. Not to mention over 400 other bird species that are yours for the watching in our lush tropical sanctuaries.

Our Caroni Bird Sanctuary boasts 150 species of bird. You'll see the legendary Scarlet Ibis fly in at dusk to roost in this vast area of mangrove and marshland. And our Asa Wright Nature Centre hosts the world's most accessible colony of Oilbirds—the only nocturnal fruit-eating bird in the world. Tobago shelters 106 bird species, including the only nesting colony of the Frigate Bird in the Southern Caribbean. The Tropic Bird, Noddy and Booby terns are indigenous to Tobago's Bird of Paradise Island.

If you're a butterfly lover, there are 622 spectacular species to be seen here. And if plants are your fancy, the Botanic Gardens in Trinidad & Tobago offer two charming wonderlands of tropical and subtropical plants. You can wander down our many nature trails, guided by a local nature society.

Venture out in a glass-bottomed boat to our famous Buccoo Reef, a natural aquarium of tropical fish and breathtaking coral gardens. You may even follow in the footsteps of Friedrich Guppy, who first identified and named the common guppy right here in Trinidad & Tobago.

So come and discover the nature of Trinidad & Tobago—a world the world hasn't discovered.

Fly BWIA International

Come discover a world the world hasn't discovered.

draft of the script, he sits down with a
of technicians and other staff mem-
and they discuss and compile a list of
fred effects. Some of these may have
invented for earlier shows, while oth-
ave to be dreamed up. The list of ef-
for one brief segment, written in
etariumese, might read as follows:

Epidyascope asteroid, add rotating
arth chord
witch on all dome strobes
Blink fade to burned-out forest pan-
rama and all sky clouds and brute
orce ring of fire

his scenario calls for a huge, pitted as-
id plunging toward the earth, followed
brilliant flash of light and a deafening
. Then the scene cuts to a panorama
nd the perimeter of the dome; the
er sees a burned-out forest, flickering
es, and clouds. This entire sequence
ffects might take all of fifteen sec-
s—and is accomplished entirely with-
the use of film or video. The produc-
team's job is to translate a scenario
as this into realistic images on the
e. Each member of the team is re-
nsible for certain kinds of effects and
ork according to his or her specialty.
he Planetarium's chief artist, Helmut
nmer, is a vigorous German-American
is considered the dean of planetarium
sts. Wimmer started his career sculpt-
and making architectural models in
many before World War II. Six days
r the war ended, Wimmer was cap-
ed by the Soviets and transported
ough labor camps in Czechoslovakia,
ngary, Romania, and finally Russia. A
del he built of one of the camps at-
cted the attention of Soviet officials,
recognized his talent and assigned
to work on the restoration of an elabo-
eighteenth-century baroque castle
later a theater complex. After his re-
se in 1949, he returned to Germany and
years later emigrated to the United
tes. He has worked for the Planetar-
ever since, painting everything from
loding galaxies to alien landscapes. He
the first artist to depict a black hole,
cially commissioned for a 1971 *Phys-
Today* cover.

Wimmer's paintings are the basis for
galaxies, nebulae, wraparound pan-
mas, and other scenes on the Sky Show
ne. Combining airbrush and sculptural
hniques, Wimmer creates an uncanny
ee-dimensional illusion. He usually
nts on a black piece of cardboard just
r a foot square. The completed paint-
s are photographed with 35-mm color
le film for projection on the dome.
Some of the most dramatic scenes in the Sky Show are of spacecraft blasting off or floating in orbit. The models of these spacecraft—as intricate and fantastic as any used in the movie *Star Wars*—are created by Brian Sullivan. In addition to his projects at the Planetarium, Sullivan builds spacecraft models for NASA and the European Space Agency, and his work has appeared in *Time*, *Omni*, and on six *Discover* magazine covers.

"As a kid," Sullivan says, "I was just nuts about models. I wanted to be a train engineer until I saw the movie *2001*." Sullivan's office in the Planetarium's basement is cluttered with his foot-long models, from several replicas of the space shuttle to complex and fanciful visions of orbiting space stations and starships.

Sullivan is forever on the lookout for material for his models. He has used plastic parts from model kits, cut-up Tupperware, light bulbs, and miscellaneous junk. One of his orbiting space stations started as a plastic ice cream lid, which he embellished with PT-109 model torpedoes and finished off with parts of model tanks. A replica of the Soviet comet probe Vega started with a light bulb. "The only difference between us and Lucasfilms," says Sullivan, "is a $25 million budget." Most

Jarless Total Body Cardiovascular Exerciser

Builds Cardiovascular Fitness More Effectively Than Any Other Exerciser

Duplicates X-C Skiing For The Best Way To Fitness

NordicTrack duplicates the smooth, rhythmic motion of cross country skiing, recognized by health authorities as the most effective fitness building exercise available.

Exclusive Flywheel Action

Provides unmatched smoothness and continuity from stride to stride. Motion and resistances are same as in real skiing.

Folds Compactly

Requires only 15" x 17" floor space.

Jarless Action is Better Than Running

Does not cause joint or back problems. More complete. Resistance on arm motion provides a superior upper body exercise.

More Complete Than Exercise Bikes

Adds important upper body exercise and provides more uniform leg muscle usage. Higher pulse rates, necessary for building fitness, seem easier because more muscles share the exercise.

More Effective and Safer Than Rowing Machines

Safer because no dangerous back strain loads imposed. More effective because NordicTrack has separate arm and leg resistance settings. All rowing machines use equal arm and leg resistance. Since your legs are 3 times as strong as your arms, rowing overworks your arms while your legs loaf.

Burns off 200 - 600 Calories per 20 Minute Workout
For effective weight control.

T. REX:

The Dinosaur Survival Adventure! For Members of the American Museum of Natural History

Members' Book Program *recommends . . .*

With lifelike graphics, this remarkable software program lets you experience, firsthand, how Tyrannosaurus lived and survived in its harsh environment. Winner of the 1985 Critic's Choice Award for "Best Science Simulation" from Family Computing Magazine. The magazine wrote: "A terrific educational simulation game—an example of how the computer can serve as a telescope into fascinating and remote worlds." Accurately based on our latest scientific knowledge of dinosaurs, it introduces kids to the whys and wonders of nature through a most exciting creature—the *Tyrannosaurus rex*! A learning game that is also great fun. Highly recommended by the Museum. For ages 8 and up, one or more players, Apple II family of computers. Joystick optional.

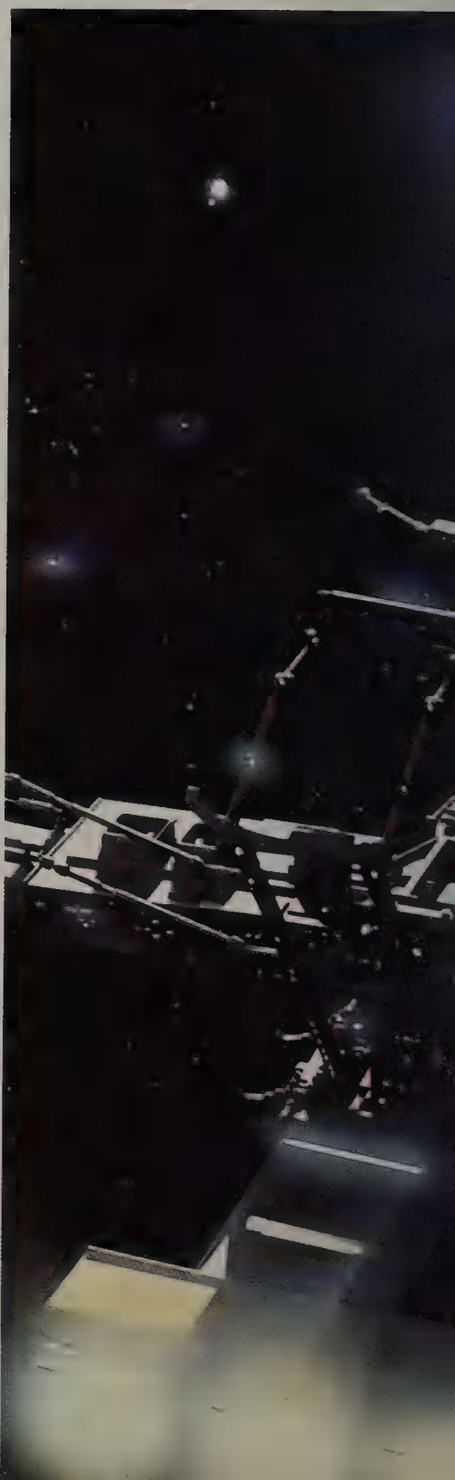
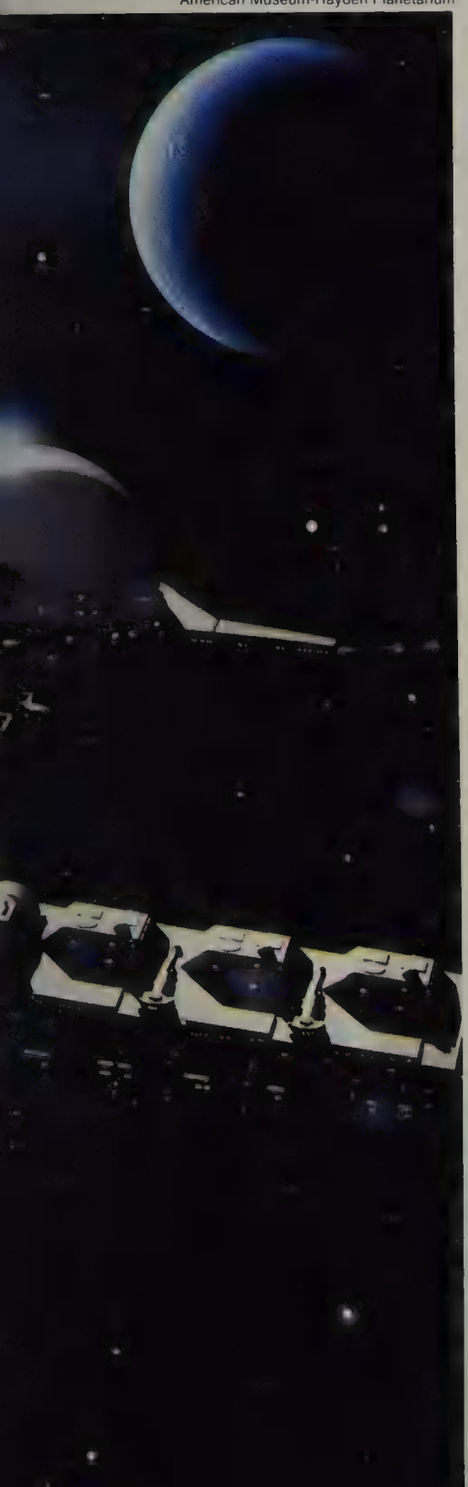
such phenomena as supernovae, rot planets, snow blizzards, expanding lae, solar flares, auroras, meteors, pling comet coma, and explosions sorts—about 200 special effects in al matter what the script calls for, M and his assistant, Joe Doti, can us build some sort of Rube Goldberg traption to fit it. Their current pr calls for creating a "globular cluster chine" by modifying several projecto that they can rotate slides covered starlike dots. A special lens, called a shooter, duplicates the star images times. The audience experiences th fect of being in the heart of a glob cluster.

Brian Sullivan's vision of a starship approaching Earth orbit

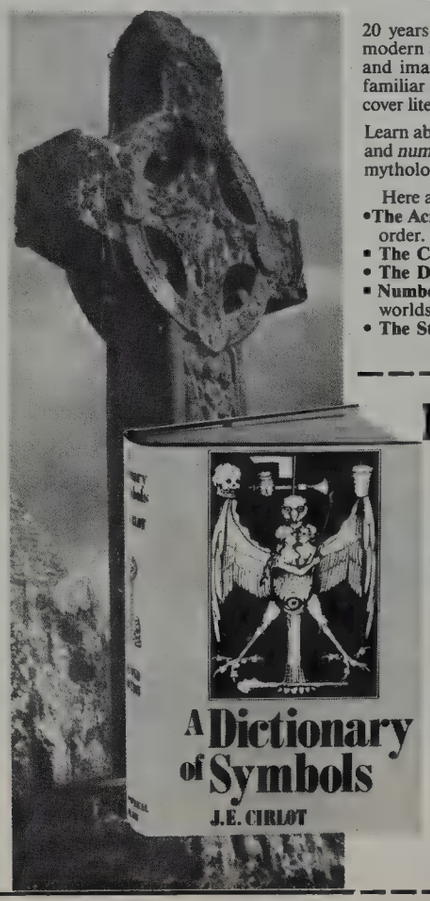


About 200 of these projectors, custom
it by Maddi and his associates, line the
netarium's perimeter, and a single spe-
effect or environment can require up
30 projectors operating *simulta-*
usly. One Sky Show can easily run
ough 1,000 or more slides. That comes
an average of one slide every two sec-
ls for the forty-minute show.
Each special effect is accompanied by
thesized sound effects, music, and nar-
ion. One of the most complicated parts
he Sky Show is timing the effects to ap-
r at exactly the right time. "In the old
s," Maddi explained, "they used to
e a guy turning knobs and pushing but-
s. But there's only so much that a man
ld do." Now the task is performed by a
r of Eagle II computers, with a third
ving as a backup. The producer of the
w, Larry Brown, writes a program to

American Museum-Hayden Planetarium



A Very Unusual Dictionary of the Origin of Symbols.



20 years ago, Juan Eduardo Cirlot, the leader of the School of Barcelona modern art movement, assembled a fascinating dictionary of symbolic words and imagery. This dictionary soon became a classic. These mysterious and familiar symbols, drawn from the religions, arts and beliefs of East and West, cover literally centuries of symbolic imagery spanning ancient times to modern.

Learn about the universal fascination with the *dragon;* the subtle power of *colors* and *numbers;* the ancient mysteries of *alchemy,* the *Tarot,* and the *Cabala;* about mythology, cosmology, and dreams and more.

Here are just a few surprising facts about symbols you will find in this book:

- **The Acrobat.** The symbol of reversal, with the power to upset the established order.
- **The Crow.** The great civilizer and the creator of the visible world.
- **The Dance.** The universal symbol for creation.
- **Number Nine.** The triplication of the triple—a complete image of the three worlds: the corporeal, the intellectual, and the spiritual.
- **The Stranger.** Stands for the possibility of unseen change.

WILD AMERICA IS OUR CAMPUS

Career programs leading to AA, B.S. and M.S. degrees

You can't fully learn about the environment by sitting in a classroom. Our expeditions are small groups of inquiring college, high school, graduate students and faculty who travel across America as a learning community. As we camp out September-May or summers—hiking, canoeing and skiing—we visit people and places to encounter deep ecological problems, society and self. Our 4-week to 4-year cross-cultural studies —Newfoundland to California—lead to naturalist, outdoor and educational livelihoods.

The Expedition Education Advantage. ❑ incorporates all previous undergraduate coursework, ❑ offers accredited career internships, independent study, life experience credit and transferable coursework, ❑ awards financial aid and career startup funding.

Send for complete information packet or inquire:

National Audubon Society Expedition Institute
Dept. H; Sharon • Conn. 06069
(203) 364-0522

Students are admitted regardless of their race, sex, religion or national origin.

control the show. The computer instru tions are recorded on the same magne tape that holds the sound track, so that t computers send their commands to all t equipment at precisely the right mome

When the system was first designed, electronic device existed that would co nect the Eagle computer to a special fects projector. A computer can only se out coded instructions, which obvious the motor on a projector could not unde stand. (A commercial company does s an interface—called a Dove—for caro sel projectors, which are also used in t show.) However, electronics technici Kai Eng still had to design and hand bui yet another device, which he named t pigeon in keeping with the ornithologic nomenclature of the system. Eng a Julio Marrero, another electronics techn cian, have now built some 200 of these i terfaces, one for each projector. Now t only button that needs to be pushed durin a Sky Show is the one that turns on t computers. (The Zeiss, however, h never been computerized, as it is easi controlled by a single operator.) The mu sic and sound effects are almost all orig nal and synthesized for each Sky Show.

At the American Museum

Museum Lecture Series

The Education Department's fall lec ture series begins in October. Among th lectures are *Sumer: Roots of Civilizatio* about the architecture, tombs, and socia life of this ancient civilization; *Jewis Communities in History*, about Jewis communities worldwide, from Ethiopia t China; *Films from the Museum's Ar chives*, featuring rare anthropological an expedition films from 1908 on; and others For information, call (212) 873-7507.

People Center

The People Center is celebrating India with a series of programs in October an November. The events include music dances, storytelling, and slide lectures o many aspects of Indian life and art. These free programs take place in the People Center each weekend from 1:00 to 4:3 P.M., and visitors are encouraged to drop in at any time.

Halley's Comet

The October members' program, *Here Comes Halley's*, will focus on the comet's upcoming appearance. Stephen P Maran, *Natural History* columnist and senior staff scientist at NASA, will give a

roducing a forty-minute Sky Show cost about $100,000 to $200,000—e modest considering the special ef-s. The Planetarium produces three or Sky Shows per year, as well as a ber of special lectures and children's grams. "The Planetarium staff," says sch, "has become rather adept at ing magic on a tight budget. It just s cleverness and a little genius." The tement of a Sky Show, Gutsch feels, ws the viewers into the subject matter ends up teaching them more about as-omy than a fact-filled lecture. And sch makes sure that all special effects, dscapes, and models are as scientifi-y accurate as possible. When the audi-e looks down the throat of a black hole, image represents a visualization of latest knowledge of black holes—not artist's fantasy.

We're here to teach astronomy," tsch says, "and the best way to do that, ur opinion, is to be entertaining as well instructive. Besides, the universe has ome so complicated in the last fifty rs that we *have* to use special effects to w what these things look like."

Douglas J. Preston

e-illustrated lecture about comets, ex-ining what they are and what they can us about the origins of the solar sys-n. He will also discuss what we can ex-t to discover as Halley approaches rth. The program is $3 for members, $6 nonmembers, and takes place on ursday, October 17, at 7:30 P.M. in the ditorium. Advance registration is re-red; please call (212) 873-1327 for re information.

upuncture Symposium

On Wednesday, October 9, the *First ernational Symposium of Acupunc-re and Electrical Therapy* will be held the Museum. (Four other sessions will e place at the Penta Hotel.) At this eting, scientists and informed layper-ns will learn about the latest develop-nts in the field of acupuncture. The ogram is free to all Museum visitors. r additonal information, call (212) 873-00, ext. 559.

orkshops for Young People

The Education Department is offering wide range of programs for young peo-e this fall. Starting in October and No-mber, the workshops include *Through e Eyes of a Child*, an introduction to the useum for very young children; *In earch of Human Origins; Origami; Se-ets of the Sea; Native American Games d Crafts;* and many more. For informa-on and a brochure call (212) 873-7507.

Learn Spanish On Your Own!

Not just a phrasebook, but a *real* language course! More than 29 hours of recorded material make this self-instructional cassette/book course a truly effective way to learn Spanish.

The course consists of a series of cassettes recorded by *native* Latin-American Spanish speakers, and accompanying textbook. You'll learn to speak Spanish the way you learned English — by listening and repeating. It's easy, and takes only 25 minutes a day. Your cassette player becomes your "teaching machine." You learn where and when you want to, and at your own pace.

The course was developed by the Foreign Service Institute to train U.S. State Department personnel. In addition, it has been used successfully by thousands of our mail-order customers.

Packaged in handsome vinyl binders, the course is available in two parts. Order either, or save 10% by ordering both:

- ☐ **Volume I: Basic.** 12 cassettes (17 hr.), manual and 464-p. text, $135.
- ☐ **Volume II: Intermediate:** 8 cassettes (12 hr.), manual and 614-p. text, $120.

(CT residents add sales tax)

Phone orders call toll-free: **1-800-243-1234**

To order by mail, clip this ad and send with your name and address, and a check or money order — or charge to your credit card (VISA, MasterCard, AmEx, Diners) by enclosing card number, expiration date, and your signature.

Try it for 3 weeks at no risk — we promise prompt refund if not completely satisfied. We offer courses in 42 languages; send for free catalog.

Planets Go Their Way

by Thomas D. Nicholson

During October the planets are more or less in transition between the morning and the evening skies. Venus is still high enough and sufficiently bright to be conspicuous in the southeast during morning twilight. As the sun continues to move farther to the east of Mars in the sky, the planet becomes easier to see in the southeast just before sunup.

Among the evening stars, Mercury is just beginning its sunset sojourn. Consequently, it will remain very low in the west after sunset and will be extremely difficult to observe. The chances for viewing Mercury improve, however, in the first week of November. Saturn, in Libra, is ending its appearance in the evening sky.

During the early part of the month, Saturn may be glimpsed very low in the southwest just after sundown. By month's end it will be lost in the sun's glare. Only Jupiter, in Capricornus, adds spice to the evening sky; it outshines any star in the night sky and can be seen low in the southeast after sunset. The first-quarter moon will pass close to Jupiter on the 20th.

Events in the calendar below are given in local time unless otherwise indicated.

October 1: The harvest moon lingers on. Although nearly three days past full, the moon rises only about an hour later than when it was full (September 28). The two stars above it, alpha and beta Arietis, are in Aries.

October 2: Apogee moon (farthest from the earth) crosses into Taurus.

October 3: Jupiter takes up its easterly drift through Capricornus.

October 4: Venus and Mars rendezvous in eastern Leo. Venus, the bright planet, is low in the southeast this morning; Mars is much dimmer and close by to the left. After Venus passes Mars tonight, they return on the morning of the 6th, still close together, but in reverse order.

October 6–7: The moon rises after 10:00 P.M. in Gemini and reaches last-quarter phase just four minutes past midnight, EST.

October 10: The morning moon is i Leo, near the constellation's brighte star, Regulus.

October 12: The late crescent moo joins Venus and Mars, which continue t be close to each other, in the morning sk Venus and the slender moon are very a tractive. Mars is also there, to their righ but dim.

October 13: New moon, at 11:33 P.M EST, is just above Spica in Virgo.

October 14: Perigee moon occurs lat today, less than twenty-four hours afte last night's new moon, raising the range o the spring tides. Look for exceptionall high tides on the morning of the 15th.

October 15: The moon's disk, barel past new, slips across the face of Mercur to occult the planet over northern Asi and the Pacific.

October 16: The sliver of a crescen moon that may be visible after sundown i not quite three days old. Saturn is above i and to its right, but the sky may not b dark enough to see the moon before it sets

October 17: The moon is nea Scorpius's Antares tonight (below and t its right) but the lunar crescent is i Ophiuchus. It passes through this little known constellation along the zodiac fo nearly half a day.

October 18–19: Look for the moo among the stars of Sagittarius on both nights. The not quite first-quarter moo shouldn't be bright enough to hide the stars of the Teapot that identify the con stellation.

October 20: First-quarter moon, at 3:1 P.M., EST, moves from Sagittarius into Capricornus, where it will be after sunset

October 21: Dust left behind by Hal ley's comet when it passed through the so lar system long ago races toward us out of the comet's orbit each fall, appearing as a shower of meteors from the constellation Orion. The Orionids reach maximum this morning, when we may be able to see up to twenty-five meteors per hour. They often look bright because their particles are moving so swiftly.

Introducing the first and only complete hardcover collection of Agatha Christie's mysteries

Now you can enjoy the greatest mysteries ever written in a magnificent Home Library Edition. Agatha Christie is the most popular mystery writer of all time. Her classic tales of murder and suspense have sold over 500 million copies worldwide. And now, for the first time ever, you can build a complete library of her timeless works with The Agatha Christie Mystery Collection.

Discover Agatha Christie's world of mystery, adventure and intrigue. The Agatha Christie Mystery Collection is your passport to a world where mystery reigns supreme.

Volume after volume, you and your family will enjoy mystery reading at its very best.

You'll meet Agatha Christie's world famous detectives including Hercule Poirot and Jane Marple. In your readings, you'll visit Egypt, Paris, England and other exciting destinations where murder is always on the itinerary. And wherever you travel, you'll become involved in some of the most ingenious and diabolical plots ever invented... "cliff-hangers" only Dame Agatha could create!

Each Agatha Christie mystery provides reading that's so exciting and so addicting... it's almost criminal. And it's yours every month with The Agatha Christie Mystery Collection.

The classic Devonshire Edition you'll be proud to display.

Solve the greatest mysteries of all time. The collection includes all of Agatha Christie's classic works including *Murder on the Orient Express, Death on the Nile, And Then There Were None, The ABC Murders* and her ever-popular thriller, *The Murder of Roger Ackroyd.* Each provides exciting and satisfying reading that will stretch your powers of deduction to their limits!

A beautiful addition to your home library. The Agatha Christie Mystery Collection is published in a magnificent Devonshire Edition that will provide beauty and enjoyment for years to come.

Each hardcover volume is Smythe sewn and printed on high quality acid-free paper that can withstand even the most murderous treatment. Bound in Sussex blue simulated leather with gold titling, the Collection will make a tasteful addition to your living room or den.

Ride the Orient Express for 10 days without obligation. To introduce you to the Collection, we're inviting you to examine the classic mystery *Murder on the Orient Express* without risk or obligation. If you're not completely satisfied, just return it within 10 days and you'll owe nothing.

However, if you're like millions of other readers around the world who love Agatha Christie's thrilling tales of mystery and suspense, keep *Murder on the Orient Express* and pay just $9.95 plus postage and handling.

You will then automatically receive future volumes once a month as they are published. No minimum purchase is required and you can cancel your subscription at any time. ***To begin your subscription, just mail us the coupon below today.***

The Agatha Christie Mystery Collection
Bantam Books, Box 957, Hicksville, NY 11802

Yes! Please send me *Murder on the Orient Express* for a 10-day free examination and enter my subscription to The Agatha Christie Mystery Collection. If I keep *Murder on the Orient Express*, I will pay just $9.95 plus postage and handling. Each month, I will receive one additional volume on a fully returnable 10-day free-examination basis. There is no minimum number of volumes to buy and I may cancel my subscription at any time. 75010

October 21–22: The moon accompanies Jupiter as they move across the sky tonight, separating slowly, with the moon moving to the east of the planet.

October 23–25: The waxing gibbous moon grows fatter nightly and stays up later as it works its way eastward through Aquarius into Pisces by the 25th. On the nights of the 23d, 24th, and 25th, the Square of Pegasus is above the moon, the star Fomalhaut is below it on the 23d and Diphda, in Cetus, is below it on the 25th.

October 26–27: After passing briefly through Cetus, the moon returns to P these nights as it approaches full p Note how rapidly the brightness in th around it increases.

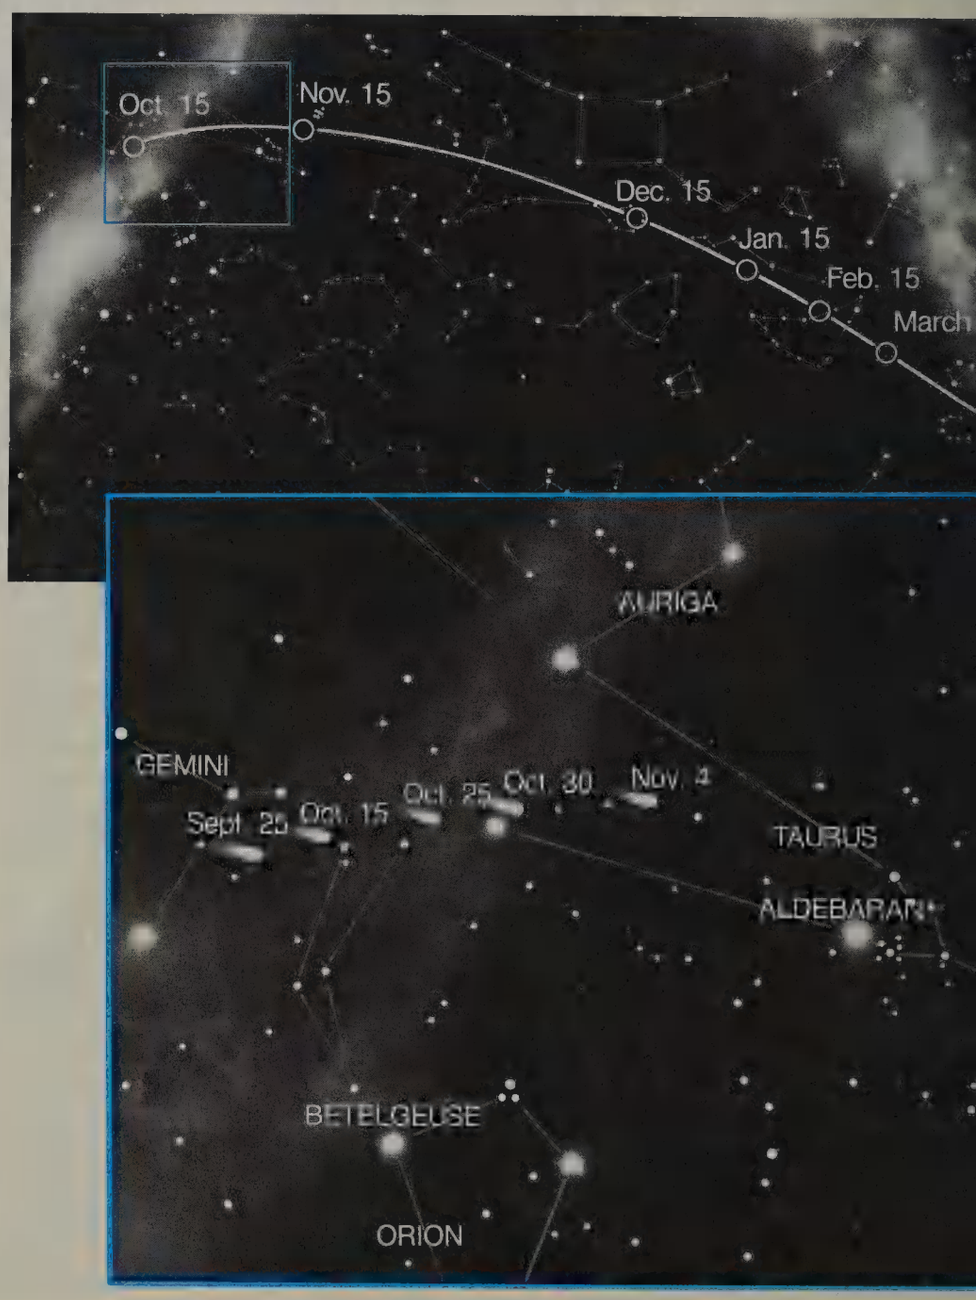
October 27: Communities using light time gain an hour when they a their clocks to standard time t (Clocks are set back one hour.)

October 28: Full moon (the hun moon) is at 12:38 P.M., when it is day over most of North America. But Alaska and parts of northwestern Ca sunrise has yet to occur, so the begin

Halley's Comeback

When comets are first discovered, they appear to be little more than faint hazy specks of light in astronomers' telescopes or on photographic plates. The only sign that they are not stars is that they move, slowly changing their positions amid the myriad of stars. This slight motion makes comets and their orbits identifiable.

Comets come of age, however, w they develop the two structures that tinguish them from other celestial jects—a coma and a tail. Halley's co already had a discernible coma last m and it should show the beginnings o dust tail this month. Toward the end o month, the comet should also bec



a total lunar eclipse can be seen there

om the Northern Hemisphere, binocu-
rs or a telescope will be necessary to
ew the comet. Under a good dark, clear
y the comet may reach naked-eye visi-
lity by mid-January 1986.

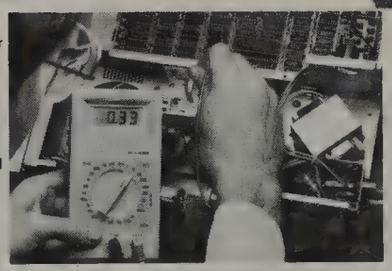
Only NRI teaches you to service and repair all computers as you build your own 16-bit IBM-compatible micro

As computers move into offices and homes by the millions, the demand for trained computer service technicians surges forward. The Department of Labor estimates that computer service jobs will actually *double* in the next ten years—a faster growth than any other occupation.

Total System Training

As an NRI student, you'll get total hands-on training as you actually build your own Sanyo MBC-550 series computer from the keyboard up. Only a person who knows *all* the underlying fundamentals can cope with *all* the significant brands of computers. And as an NRI graduate, you'll possess the up-to-the-minute combination of theory and practical experience that will lead you to success on the job.

Your NRI course includes a Sanyo 16-bit microcomputer with 128K RAM, monitor, with double-density/double-sided disk drive, and "intelligent" Keyboard; The NRI Discovery Lab®, Teaching Circuit Design and Operations; ■ Digital Multimeter; Bundled Spread Sheet and Word Processing Software Worth over $1000 at Retail—and More.



NRI is the only home study school that trains you as you assemble a top-brand computer. You'll install and check keyboard, power supply, disk drive and monitor, following step-by-step directions.

You learn at your own convenience, in your own home, at your own comfortable pace. Without classroom pressures, without rigid night-school schedules, without wasted time. Your own personal NRI instructor and NRI's complete technical staff will answer your questions, give you guidance and special help whenever you may need it.

The Exciting Sanyo 16-bit IBM compatible Computer—Yours To Keep

Critics hail the new Sanyo as the "most intriguing" of all the IBM-PC compatible computers. It uses the same 8088 microprocessor as the IBM-PC and the MS/DOS operating system. So, you'll be able to choose thousands of off-the-shelf software programs to run on your completed Sanyo.

As you build the Sanyo from the keyboard up, you'll perform demonstrations and experiments that will give you a total mastery of computer operations and servicing techniques. You'll do programming in BASIC language. You'll prepare interfaces for peripherals such as printers and joysticks. Using utility programs, you'll check out 8088 functioning. And the entire system, including all the bundled software and extensive data manuals, is yours to keep as part of your training.

100-Page Free Catalog Tells More

Send the coupon today for NRI's big 100-page color catalog, which gives you all the facts about NRI training in Microcomputers, Robotics, Data Communications, TV/Video/Audio Servicing, and other growing high-tech career fields. If the coupon is missing write to NRI at 3939 Wisconsin Ave., NW, Washington, DC 20016.

fluorescence of the gases combine to cause the halolike coma to appear. Still later in the comet's race toward the sun, the material is swept away, the dust is diffused by the sunlight's pressure of radiation to form a sharply curving tail, and the ionized gases are deflected by the solar wind into a long, straight tail of fluorescing matter.

What can we expect of Comet Halley's coma and tail this time around? These structures vary widely from comet to comet, reflecting differences in the ratio and density of the gases and dust. A comet may also vary from one appearance to the next because on each time around, it presents different layers of matter to the sun and the old layers are blown away. Should the coma and tail be closely replicated from one solar pass to the next, their appearance would still depend on the comet's path relative to the earth. And even the best of tails palls when seen head-on from a great distance. Judging by its past appearances, Halley's comet should produce a spectacular coma and tail.

During the comet's last passage around the sun, its coma was estimated to be 40,000 miles or more in diameter. The tail developed more slowly before perihelion and reached its greatest length six to seven weeks later, when it grew to be about 50 million miles long, more than half the distance between the sun and the earth. That suggests that the longest tail during this trip may occur in March 1986, shortly before the comet's close approach to the earth on April 11.

Unfortunately, when Comet Halley's tail may be at its longest next spring, we will be looking at it virtually head-on, and it will be more than two and a half times farther away from the earth than it was in 1910 under the same circumstances. That doesn't bode well for the tail's appearance in our skies. Worse still for Northern Hemisphere viewers, the comet will be in the direction of Sagittarius and Scorpius in late March and early April. If you know the summer evening sky, you will realize that these constellations never rise very far above our southern horizon (see the July Sky Map). Neither will Halley's comet. We can expect it to be up in the dark sky for only about two hours or so in the early morning, with its tail preceding and towering above it. As we view those constellations and Halley's comet from more southerly latitudes, we will see all three earlier and higher in the night sky. Fr the southern parts of South America, A tralia, and New Zealand, however, comet will be visible all night long, wh explains why eager comet watchers migrate south late this coming winter a early spring.

Northern comet seekers get their t this fall, before perihelion, as Halle comet approaches and then passes opp tion from the sun in late November. Fr now through November 27 (the come closest approach to the earth before pe helion) and until mid-January (when comet moves too close to the sun to be se from the earth), we in the north have decided edge. True, the comet will pro bly not have much of a tail, but it will virtually as bright for us in January a will be in late March for those south of equator. By mid-October, Halley's com will have come to within 150 million mi of the earth and should brighten to ab magnitude 10, within range for a thr inch-aperture telescope. By the end of month, it brightens by another full mag tude, bringing it within reach of expe enced skywatchers with binoculars.

The Way We Eat Now

Lacking a traditional cuisine, Americans are using ideas from a variety of national pasts

by Raymond Sokolov

In the fuggy heat of late spring this year, one thousand people in formal dress trooped down to New York's Rockefeller Plaza to eat the splashiest buffet dinner in gourmet memory. Each diner paid a minimum of $250 for the privilege of tasting food prepared by a dozen innovative chefs from around the country. The contributions, every last cent of them, went to City Meals On Wheels, a program sponsored by the New York City Department for the Aging that brings hot food to the housebound elderly. All in all, it made a dignified and appropriate wake for James Beard.

Beard had died, at age eighty-two, a few months before this memorial celebration, after years of intermittent illness and many decades as the uncrowned king of the American culinary world. This portly, sensual buddha of food had thrown his great influence behind City Meals On Wheels with the same generosity that had launched and fostered the careers of scores of people in the food field. Indeed, several of his more recent protégés had come to Rockefeller Plaza from their own newly famous restaurants to serve their specialties.

This food, much of it squarely in the center of what has been called American *nouvelle cuisine*, made a fitting tribute to Beard's crucial role in guiding and refining the nation's growing culinary sophistication. No one had done more to preserve traditional American food ideas, but no one had ever supported the creativity of young chefs with greater energy and intelligence than Beard.

The menu that night ran the gamut from the solidly old to the tremulously new. Larry Forgione of Manhattan's An American Place prepared a well-known Beard recipe for strawberry shortcake (see recipe). Bradley Ogden of San Francisco's Campton Place Hotel struck the eclectic note of today with blue corncake with caviar. Paul Prudhomme, the bearded and Beard-size New Orleans restaurateur, overwhelmed Rockefeller Center's ventilation system with the smoke from his Cajun blackened redfish. At other buffets, representing other restaurants, there was orthodox Spanish roast suckling pig and unorthodox grilled shrimp-and-scallop brochette with peanut chili butter (see recipe).

Had Beard been present for this ambulatory feast, he would surely have been struck by two things: the emphasis on regional or ethnic specialties and the readiness to combine ideas and ingredients that had never been mixed before. If cooking had ever had a "modern" period, it would be appropriate to call this new menu postmodern. Certainly it shares with postmodern architecture an unabashed zest for slapping together classic motifs and elements of the past in unexpected and ostentatious ways. None of this would have escaped Beard, who had so lovingly wallowed in classic American cookery and watched it coalesce into a cuisine.

That was the trend, at any rate, that Beard proclaimed more than a decade ago. He thought he saw a national cuisine evolving out of all the bits and pieces, the snickerdoodles and flautas and scrapples, that until then had resisted confederation into a coherent, European- or Asian-style cuisine. At the time, I thought he had succumbed to a delusionary bout of gastropatriotism. Now, however, given the evidence of the Rockefeller Plaza evening and certain recent experiences in other restaurants, and after reading some of the new cookbooks coming out of the West, I begin to think that Beard had sensed the wave of the future long before it actually swelled.

What is afoot in our land is not the birth of a vernacular cuisine in the traditional sense. That would be impossible. Wit exception of Native American recipe cluding Aztec dishes that may have eaten here before geopolitics conv them into Mexican food), nothing we sume has evolved in the autochtho slow manner that produced the cuisir traditional cultures. We lack, fur more, the standard focuses of cuisin mation; we have no court and no peas It was, in fact, in the American analo of royal and peasant kitchens that ou gional dishes did develop—in the br creative moments of princely wealth i lonial cities and southern plantations when pioneers adapted European cui to the natural world of the frontier. these short periods of culinary inve did not survive the homogenizing forc settlement. Regional dishes survive relics, endangered items on a menu tro out mostly for visitors.

A typical example of this kind of s case regionalism flourishes near the ver rail yards. The Buckhorn Excha bills itself as a "historic museum, res rant and saloon." The two-story Victo building is chock-full of game trop and frontier art. The menu features Ro Mountain oysters (sheep testicles: ob chewy, and insipid), buffalo, and elk.

In the real world outside, a monstro efficient agribusiness network, lin farming regions by truck with big-city permarket chains, has long since un mined true gastronomic regionalism most completely. As a creative prop tion, regionalism dried up when poly immigration swamped the eastern ci pristine colonial cultures and when m anization sent farm families packing find jobs in town.

But the regional foods did not c pletely perish, and knowledge about th persisted and spread, especially a 1980. By then, a generation of Americ

Carol Lawson

e first doll in an enchanting
w suite of fairy tale dolls
this renowned British artist.

rafted in fine porcelain.
dividually hand-painted. $60.
ease mail by October 31, 1985.

ce upon a time there was a little girl who
ed in a wonderful world of make-believe.
e little girl grew up to become an artist of
own, re-creating that fairy-tale world again
l again in some of her finest work.

Now Carol Lawson, for that is the little
l's name, has created her very first costume
l: Goldilocks. Inaugurating a suite of dolls
t portrays the most delightful heroines from
world's best-loved fairy tales.

Carol Lawson's Goldilocks is thoroughly
chanting. She has been handcrafted with all
charm and care of the fine collector dolls of
steryear. Her bisque porcelain head, hands
l feet have been sculptured in meticulous
ail, and her lovely face painted by hand.

Goldilocks' costume has been designed just
her. With all the special little touches one
uld expect from a Carol Lawson creation.
tice, the blue satin bow perched atop her
den curls . . . her ruffled pink-and-white
ka dot dress accented with tiny satin
sebuds. Even her own pet teddy bear.

The result is a completely entrancing
w collector doll that combines the finest
ftsmanship with the very special magic of a
rol Lawson original.

Goldilocks is available exclusively from
anklin Heirloom Dolls, and only by direct
plication. The price for this delightful
rol Lawson doll is just $60—which may be
id in convenient monthly installments.

Each imported doll will bear the
stinguishing mark of Franklin Heirloom Dolls
d will be individually crafted under their
se supervision. Each will be accompanied by
Certificate of Authenticity bearing Carol
wson's signature, together with a specially
itten commentary about the fairy tale that
spired this lovely work. In addition, a stand
ll be provided on which to display the doll at
additional charge.

To acquire Goldilocks, no advance payment
required now. However, the accompanying
plication should be returned by October 31st.

Doll shown much smaller than actual size of approximately 12" in height.

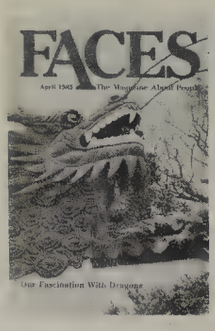
Museum Members entitled to $2.50 discount off subscription price!



had lived through the so-called culinary revolution. They had been to Europe and had learned firsthand what traditional cuisines were and how to cook them. They had also observed how the most famous French and Italian restaurants prided themselves on keeping regional foods and food ideas alive on their tables. By 1980, a new freedom had also swept through previously conservative and culture-bound French restaurant kitchens. The *nouvelle cuisine* reveled in exotic ingredients and bizarre food combinations presented with a Japanese flair.

By 1980, French *nouvelle cuisine* restaurants had opened in this country on both coasts. But at the same time, Americans well grounded in French ideas combined the new European grammar with an American vocabulary. Especially in California this meant mixing ingredients with ahistorical abandon and putting special emphasis on ingredients of a markedly local and recherché sort—wild mushrooms, native chestnuts, fiddlehead ferns.

At Rockefeller Plaza, one of the practitioners of this new eclecticism, Jeremiah Tower, passed out menus from his San Francisco restaurant, Stars. Among the daily specials listed were lobster gazpacho, mint aioli, rillettes of smoked fish, and oysters with spicy lamb sausages.

You don't have to travel to California to sink your teeth into this *nouvelle* mash. You can try it yourself at h thanks to two new books. Should you to sample the deep-fried catfish in nese sauce made from sake, rice vi and soy sauce that Wolfgang Puck vides diners at Chinois on Main in S Monica, there is a recipe for it in I and Paul von Welanetz's *L.A. Cu The New Culinary Spirit* (Tarcher). same primer will open the way for y taste John Sedlar's Franco-Santa Fe ing, as exemplified by the green relleno, stuffed with mushrooms du and served with garlic chèvre sauce, he prepares at Saint Estephe in Ma tan Beach, California.

There is more of the same in I West Eckhardt's *The New West C Cuisine* (Tarcher), from saffron chall jalapeño hollandaise. Eckhardt expo a new cuisine she sees pullulating Vancouver to San Diego. Her re stress local products, the Pacific coast nic mix, and the health food "traditi

I am not convinced that her cranb salsa or any of the other concoctions i book will survive into the next cen But I do think that some of the dishe and her wild western colleagues are rently making up will turn into clas Even if they don't, it is the approach matters.

Two recipes slightly adapted from *A Celebration of James Beard* (a booklet distributed at the City Meals On Wheels dinner)

Jonathan Waxman's Grilled Shrimp-and-Scallop Brochette with Peanut Chili Butter

- 4 ounces shelled Key West shrimp
- 4 ounces fresh sea scallops
- 1 lime
- 2 tablespoons olive oil
- 1 serrano chili
- 1¼ cups shelled roasted peanuts
- ¼ cup sweet butter cut into small cubes
- Salt and pepper
- ¼ cup sweet butter cut into large cubes
- 2 tablespoons chopped parsley

1. Mix shrimp and scallops with juice of 1 lime and 1 tablespoon olive oil. Skewer shrimp and scallops on four brochettes, alternating shrimp and scallops. Marinate for one hour.
2. Deseed and stem the chili, then chop fine. Put peanuts into the jar of a food processor, followed by chili, small cubes of butter, and remaining tablespoon of olive oil. Pulse machine to purée. Season to taste with salt and pepper. Transfer to a medium saucepan.
3. Make a sauce by adding ½ cup ice-cold water to purée from processor. Place over medium heat. Add large cub butter and beat with a wooden s until homogenized. Adjust season
4. Grill brochettes over medium-flame on a charcoal grill 2 to 3 utes, turning once. Transfer to ser plate. Spoon sauce beside broch and sprinkle with parsley.

Yield: 4 brochettes

James Beard's Shortcake

Biscuits

- 4 cups all-purpose flour
- ¼ cup plus 2 tablespoons sugar
- 3¼ teaspoons cream of tartar
- 1¾ teaspoons baking soda
- 2 teaspoons salt
- 6 ounces unsalted butter, chilled cut in small bits
- 1½ cups heavy cream
- 4 hard-cooked egg yolks, mashed
- 4 tablespoons unsalted butter, mel

Berry Filling

- 3 pints berries, such as raspber blackberries, or strawberries
- 2 tablespoons sugar
- 1 pint English double cream or 1 heavy cream, whipped

1. Heat oven to 375 degrees.
2. For the biscuits, sift flour, su cream of tartar, baking soda, and

ie von Welanetzes are definitely on to ething when they talk about the new iary spirit. The Californian willing- to experiment is not just an unbridled enture. Most of the people getting into very interesting act are building on l knowledge of several vernacular tra- ons and mixing them up with a good se of what will work and what won't. To te the classic French emulsified sauces n chili is not barbaric; it follows logi- y from age-old Provençal practice— y aioli, a garlic mayonnaise, points to- d "hot" hollandaise. With the fiercer erican newcomer, something is lost, naps, but something is gained.

The main interest of postmodern Amer- n cuisine, at this early stage, is its free informed attitude toward the rich ld of possibilities open to American ks. Perhaps a vocabulary of new nerican" dishes will ultimately shake of all the fervid experimentation. But how it is the process that counts. The nipulation of local ingredients with cu- ry ideas inherited from many national ts is a sensible extension of the notion he melting pot—and an intrinsically erican way to go.

ymond Sokolov is a writer with a spe- l interest in the history and prepara- of food.

nto a bowl. Cut in butter bits with a pastry cutter or by working quickly with fingertips. The pieces of butter should be blended until quite small. Add cream and mashed yolks and stir quickly until dough clings together.

Turn out on a floured board, knead a few times, and pat or roll out to ½- to ¾-inch thickness. With a 3-inch, floured cookie cutter, cut 6 rounds, and with a 2½-inch cutter, cut another 6 rounds. If needed, use scraps to re-roll. Arrange larger rounds on lightly buttered cookie sheet. Brush each with a teaspoon of melted butter. Top with 2½-inch rounds and brush tops with butter.

n a small bowl, mix berries and sugar, oss, and let sit while the shortcake is baking.

Put cookie sheet with biscuits in a pre-heated oven on middle shelf. Bake until firm to the touch and golden brown, 12 to 16 minutes.

Transfer the biscuits to serving plates and remove the top (smaller) layers very carefully. Spoon the berries over the bottom layers and put a dollop of cream on each one. Place the smaller layers on top of the cream and serve immediately. Serve the rest of the cream on the side.

Yield: 6 servings

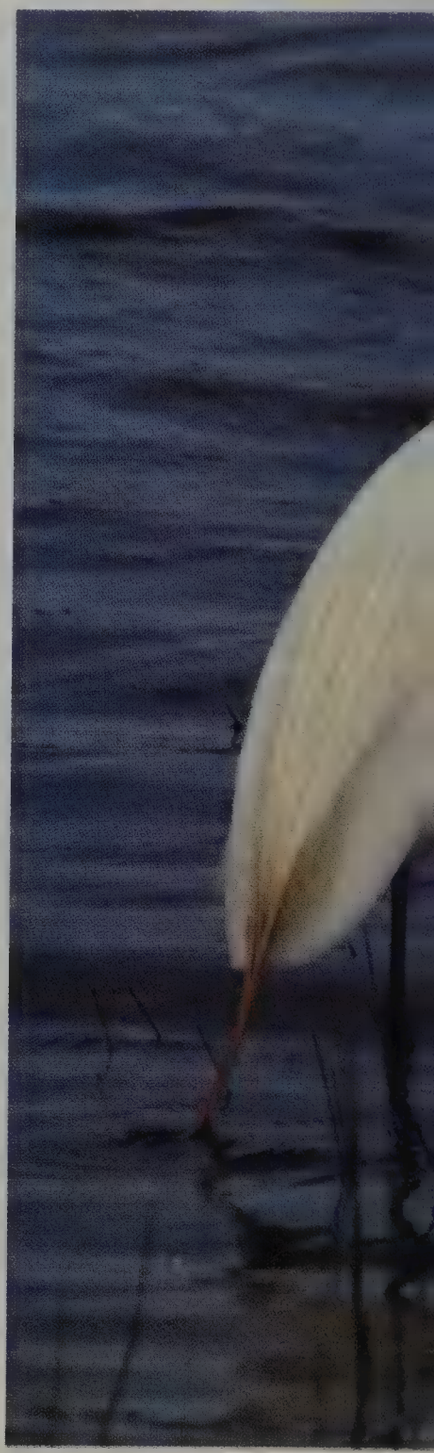
The Catcher in the Marsh

Photographs by Townsend P. Dickinson



Early one May morning, while dri
slowly through Chincoteague Nati
Wildlife Refuge on the eastern shor
Chesapeake Bay, photographer To
send Dickinson spotted a great egret
aging near a dike at the edge of a fresh
ter impoundment. Dickinson stop
turned off the engine, got out of the
and using the car as a blind, rested
camera on a shoulder holster and focu
on the bird.

Suddenly, the egret plunged its bill
the marsh vegetation at the edge of
water. Then, stepping back, it brough
a medium-sized rodent (whether it w
meadow vole or a Norway rat was ne
determined because the animal soon
came inaccessible for positive identif
tion). The animal struggled briefly, but
tilely, and soon went limp.

The bird then maneuvered the roden
as to swallow it headfirst, but appare
decided it was not quite ready to eat. S
holding the dead animal in its bill,
great egret dipped it in the water, gave
powerful squeeze, and repositioned it
swallowing. The dipping, crushing,
positioning sequence was repeated seve
times over until the egret finally sw
lowed the rodent.

The whole procedure took less than f
minutes. To take this series, Dickin
used a 400-mm lens on his hand-held ca
era and shot the photographs at a h
shutter speed to minimize any possi
camera movement.

The great egret (*Casmerodius alb*
usually feeds on crustaceans, fishes, fro
snakes, and an occasional small mamm
In this case it had to handle a larger-th
usual mouthful, but it lived up to its re
tation as an opportunistic and omnivor
predator.

Additional Reading

Burma Fossils (p. 26)

Russell L. Ciochon's "The Search for Fossil Man in Asia" (*The Explorer,* Winter 1976, pp. 7–17) is a lively account of the quest for early man in Burma and other parts of Asia and the explorers who carried it out. *Primate Evolution and Human Origins,* by Ciochon and John G. Fleagle (Menlo Park, CA: Benjamin Cummings Publishing Co., 1985), includes a pertinent review of prosimian and early anthropoid evolution, as well as sections on the origin and evolution of the human lineage. Ciochon and A.B. Chiarelli edited *Evolutionary Biology of the New World Monkeys and Continental Drift* (New York: Plenum Press, 1980), which looks at these monkeys from a wide perspective, ranging from anatomy and paleontology to biogeography and continental drift theory. Several chapters discuss *Amphipithecus* and *Pondaungia.* Edwin Colbert, the noted American Museum paleontologist who published the original description of *Amphipithecus,* "A New Primate from the Upper Eocene Pondaung Formation of Burma" (*American Museum Novitates,* No. 951, 1937), was also the first, in this article, to make a strong case for the origin of the anthropoids in Asia. Barnum Brown, who collected fossils for the American Museum during the first half of the twentieth century, wrote a popular account of his expedition to Burma for *Natural History* (May–June 1925, pp. 294–308). Also interesting is Colbert's *The Great Dinosaur Hunters and Their Discoveries* (New York: Dover Publications, 1984), which recounts some of Brown's most famous discoveries and accomplishments.

Wild Radishes (p. 46)

A.C. Martin's *Weeds* (New York: Golden Press, 1972) is one of the best guidebooks available. It provides a good introduction to the subject, is suitable for children as well as adults, and is reasonably inexpensive. Like *Weeds,* C.B. Clarke's *Edible and Useful Plants of California* (Berkeley: University of fornia Press, 1977) is available in p back; it is chock-full of information wild radish and other weeds and ev cludes recipes. C.A. Panetsos and Baker uncover the unusual species variation in wild radish in "The Ori Variation in 'Wild' *Raphanus sativ* California" (*Genotica,* vol. 38, pp. 74). "Gene Flow in Seed Plants," by Levin and H.W. Kerster (*Evoluti Biology,* vol. 7, pp. 139–220), is the c review of dispersal of pollen and seed tailing and evaluating hundreds of e mental and descriptive studies.

Humpback Whales (p. 52)

Lois King Winn and Howard E. W *Wings in the Sea* (Hanover, NH: U sity Press of New England, 1985) is a ough, reliable, and up-to-date accou the humpback whales. *Cetacean B ior,* edited by Louis M. Herman York: Wiley-Interscience, 1980), inc a number of chapters about humpb

Oriental Passag

April 4 to May 7, 19

Relax on the Museum's exclusively chartered cruise vessel, *Illiria.* This small gem of a ship offers pampered service, superb food, and luxurious surroundings. Each excursion on land is designed to provide a rich and diversified experience of the history, art and culture of the ancient world. And the trip offers leisure to enjoy swimming, strolling, shopping or simply relaxing.

Halley's Comet, together with a lecture team, itinerary and cruise vessel that cannot be duplicated...call or write the Museum's Discovery Tours office for detailed information.

ling coverage on the whales' com-cation systems and songs as well as pertinent topics. Roger Payne edited *nunication and Behavior of Whales* der: Westview Press, Inc., 1983), a of articles based on lectures pre-l at a AAAS symposium that deal humpback songs, vocalizations, be-r on the breeding grounds, and pat-of migration. The humpbacks' social ization at their wintering grounds in ii and the Caribbean is treated in Pe-yack and Hal Whitehead's "Male petition in Large Groups of Winter-umpback Whales" (*Behaviour,* vol. p. 132–54). The whales' broadside ys, head lunges, charge-strikes, and characteristic aggressive behaviors e grounds are discussed by C. Scott r and Louis M. Herman in their tech-article "Aggressive Behavior Be-n Humpback Whales (*Megaptera eangliae*) Wintering in Hawaiian rs" (*Canadian Journal of Zoology,* 2, pp. 1922–37).

Desert Palm Oases (p. 64)

When it is released sometime late in November, James W. Cornett's *Ecology of the Desert Palm Oasis,* published by the Palm Springs Museum, 101 Museum Drive, Palm Springs, CA 92263, will constitute the most exhaustive treatment of palm oases to date. The book's nine chapters will cover the hydrology of the oases, the growth and development of fan palms as well as their ecology, and the birds and other animals that live there. Palm aficionados may wish to contact the Palm Society (P.O. Box 368, Lawrence, Kansas 66044), which publishes a quarterly journal, *Principes,* especially for them. Articles range from technical papers to anecdotal reports of personal experiences with palms, and fan palms are often covered. The late Randall Henderson, who carefully counted individual trees and kept records on the palm oases of the Colorado Desert, wrote a series of articles about them for *Desert* magazine, which he edited and published. The articles, forty or so in total, appeared from 1938 to 1965.

Chilean Mummies (p. 74)

Since most of the Chilean mummies have been rediscovered in bulk only recently, not much has been written about them yet. An excellent source of information, however, is available to those who can read Spanish: *Chungara Arica,* a journal put out by the Instituto de Antropología at the Universidad de Tarapacá, Chile. The November 1984 issue (volume 13) contains a number of articles about the Chinchorro. The late noted archeologist Junius B. Bird discussed the Chinchorro and described his unearthing of a grave site in "Excavation in Northern Chile" (*Anthropological Papers of the American Museum of Natural History,* vol. 38, part 4, 1943). Marvin J. Allison's "Paleopathology in Peru" (*Natural History,* February 1979, pp. 74–82) reports on his studies of ancient Indian mummies, which revealed that some industrial diseases are more than 2,000 years old.

Authors

In 1975, **Russell L. Ciochon** (page 26) laid plans for an expedition in search of the origins of the higher primates. His quest took him to a remote part of Burma, explored earlier in this century by Barnum Brown, the American Museum's legendary fossil collector. Ciochon is pictured (far right) with (left to right) his American co-worker, paleontologist Donald E. Savage, and Burmese geologists Tin Maung Oo, U Ba Maw, a Thaw Tint. Related fieldwork has t Ciochon to China, India, and Indon He did his graduate work at the Un sity of California at Berkeley and taught at the University of North C lina at Charlotte. He is currently search associate in the Departme Anatomical Sciences at the State versity of New York, Stony Brook.

Norman Ellstrand (page 46) suspected that California wild radishes were up to something more than simple mating. His interest in the sexual practices of this unusually varied weed species was sparked during a general study of the breeding systems of other plants. Convinced that basic questions could be answered only by identification of parent plants, Ellstrand brought the precision of genetics to bear on his fieldwork. His research confirms that multiple paternity occurs in plants and also delineates its possible mechanisms. An assistant professor of plant ecology at the University of California at Riverside, Ellstrand has launched a plan for commercial production of the New World fruit cherimoya on the West Coast. When not in the field or the lab, Ellstrand devours fiction—fantasies, mysteries, and science fiction. A cherished ambition is to write a successful novel himself.

ust because somebody has a Ph.D. sn't mean he knows exactly what he ts to study. After five years of pursu- humpback whales to the ends of the th Pacific, **C. Scott Baker** (page 52) s he is "just beginning to see what stions are interesting." Baker, whose toral work at the University of Ha- i has focused on seasonal contrasts in great black whale's behavior, wants consider what individual whales are ng. "We have an unfortunate and que situation in the North Pacific, in t hunting has reduced the population umpbacks to only about 1,200 ani- s," he says. "This means we can indi- ually identify a large percentage of whole population. You could never that with dolphins, for example." owing individual whales means that mpback researchers can look at the ales' sex life and migration patterns in ch greater depth. Coauthor **Louis M. rman** is the director of the Kewalo Ba- Marine Mammal Laboratory at the iversity of Hawaii, where he has stud- humpback whales and dolphins since 70 and sponsored students like Scott ker. He is also a professor in the uni- sity's psychology department, and he ches animal behavior, especially ma- e mammal behavior. Herman re- ved his Ph.D. from Penn State Uni- sity. His book, *Cetacean Behavior,* s published in 1980 by Wiley erscience.

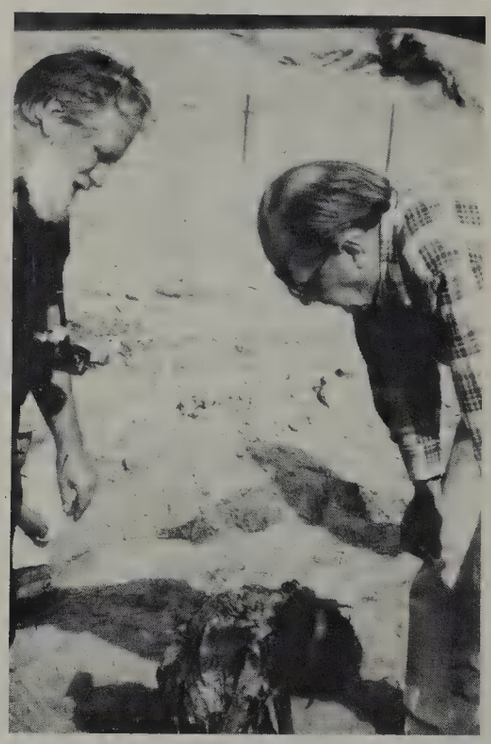
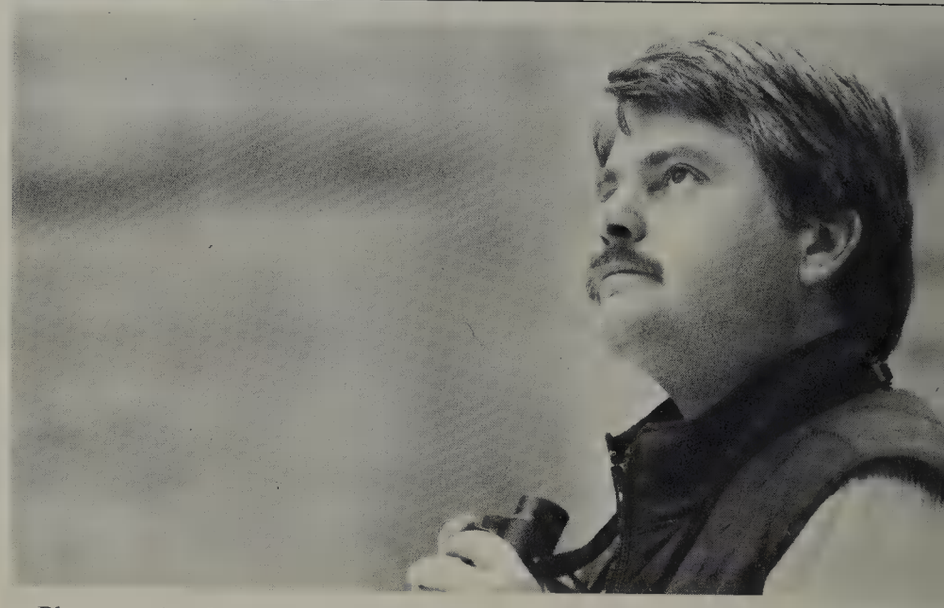
Plant and animal ecologist **James W. Cornett** (page 64) says, "I have been enthralled by the beauty of desert palm oases since I was a teen-ager, but it wasn't until I was a graduate student that I began to examine the oases seriously." That interest explains how he came to write about palm oases in this issue. Cornett became curator of natural science at the Palm Springs Desert Museum in 1980 after working there for five years. Field trips to study the ecology of desert organisms have taken him to the southwestern United States, the Atacama Desert of Chile and Peru, the Australian Desert, and the Vizcaíno Desert of Baja California. Investigations of two more deserts—the Gobi and Sahara—are part of his future plans.



In 1969, while on an assignmen the Standard Oil Company in **Marvin J. Allison** (page 74) becam trigued by the medical histories o natural (sun dried) mummies. In he started studying the artificial m mies of northern Chile as an avoca while he taught clinical pathology a Medical College of Virginia in mond. Although he is still affiliated the medical college, Allison is now a time faculty member at the Unive of Tarapacá in Chile and has an offi amid hundreds of mummies—at the versity's Museum of Archeology o outskirts of Arica. Allison and his leagues adapt many modern techni of forensic pathology to study the cient mummies. He is shown here (a right) with *Natural History*'s ed Alan Ternes, at one of the grave sit northern Chile.



Photographer **Townsend P. Dickinson** (page 116) bought his first New York Lotto ticket for the $41 million prize in August. "If I'd won," he says, "I would have spent the rest of my life out in the field photographing birds." As it is, he spends much of his time indoors working as the senior photo editor at a commercial photographic stock house in New York City. But birds are his first love. He doesn't photograph them simply looking pretty, as though posed for an ID card or a nature yearbook. Instead, he tries to catch them doing something teresting. To find out what that m be, he reads a great deal of the scien literature on bird behavior. Then in free time, and financing most of his t himself, he journeys forth armed w binoculars, camera, lenses, and patie A project Dickinson would like to ca out is to visit all the sea bird colo ringing the North Atlantic. His ph graphs in this issue were taken wit high-speed, motor-driven Canon F-1 a 400-mm lens.

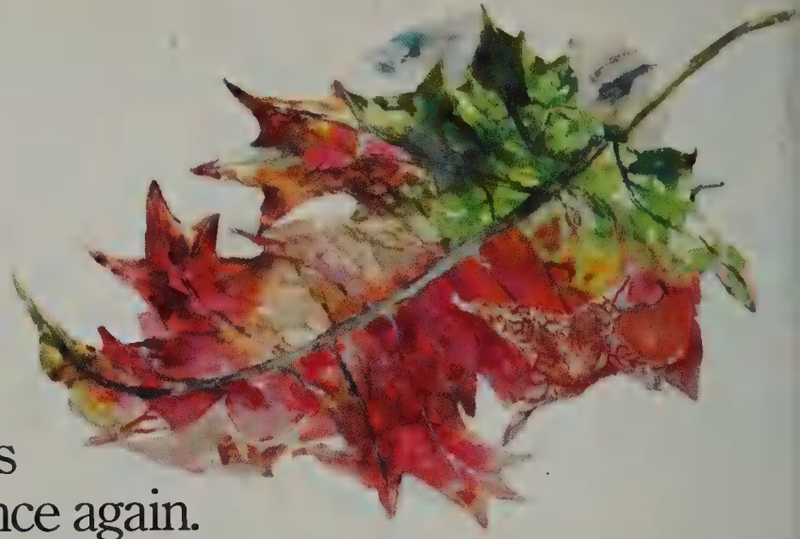
Reasons for seeing Europe this fall keep piling up.



As the leaves turn russet gold and cover Europe with a winter coat, the throngs of summer visitors head for home. The long lines vanish. And Europe goes native once again.

London fills with bowler hats and brollies. The Champs Elysées rings with Parisian gossip, and peace settles over the Sistine Chapel.

The crazy, heady summer sun gives way to gentle autumn. And with the heat go the prices.

An already reasonable Europe now becomes ridiculously good value, in the shape of TWA's Getaway® Vacations.

Book before December 1, 1985, and a fifty dollar rebate will give you eight days in London for $79–$198, Rome for $68–$168, Paris for $139–$228, or the Costa del Sol for $99–$189,

depending when you travel. That doesn't include your airfare, but it does include a budget hotel (per person, double occupancy), breakfast every morning, a sightseeing tour, and, where possible, free theatre, musical and nightclub tickets. For a copy of our fall and winter vacation brochure, call 800-G-E-T-A-W-A-Y or your travel agent.

Then watch while the summer hordes turn quietly green.

Thanksgiving in the Monte

In the dense forest of Paraguay, an anthropologist and a family of hunter-gatherers share a feast

by Kevin T. Jones

I took one last glance back at the truck and was filled with the same mingled anticipation and dread I had experienced as a child when my mother left me at the bus station for a trip to visit relatives. But this time Hillard Kaplan, my anthropologist colleague from the University of Utah, had dropped me off, and I was heading into the jungle on a hunting and gathering expedition with a band of Aché Indians. Kaplan had driven me, Kim Hill, the leader of our research group, and twenty-four Aché as far down the road past the newly cut fields as the pickup could go. From there we set out on foot into the heart of the Aché's traditional territory, the thick forest, or *monte,* of eastern Paraguay. It was Thanksgiving Day, 1984.

We had walked for only about fifteen minutes when Kuaregi, the oldest of three brothers whose families made up the core of the group, took an ax and began chopping into the rotting wood of a fallen pindo palm tree. Several people gathered excitedly nearby, and I soon found out why: Kuaregi was chopping out the big, fat, white palm beetle larvae known as *buchu.* Someone handed me one, and I held it awkwardly, amazed at the strength of the 1½-inch-long grub and aware of its nasty-looking jaws. Kim showed me how to pinch off the head and said, "Just pop it into your mouth. It tastes like creamed corn." The Aché were eating the grubs with gusto, and rather than think about it, I put the larva in my mouth and chewed away. It did taste like creamed corn, but the skin was unexpectedly tough, something like I imagine raw chicken skin might be. "Welcome to the *monte,*" Kim said. "Happy Thanksgiving."

We were in Paraguay to study the ecology, demography, child care, and archeology of the Aché, research sponsored by the National Institutes of Health. Hill had lived and worked with the Aché for more than three years since 1978; Kaplan had spent nine months with them in 1981 and 1982. This was my first visit.

Until recently, the Aché, traditional hunter-gatherers, roamed the neotropical forests between the Paraná and Paraguay rivers, subsisting on wild game, fruits, vegetables, and honey. Their technology was simple but perfected to exploit the region's resources. The men carried powerful palmwood bows and long, barbed arrows. The women managed large burden baskets, or *nokos*, plaited from pindo palm leaves, as well as stone-bladed axes, beeswax-covered baskets for transporting water, woven mats and fans, and of course, children. The Aché love pets and often keep young capuchin monkeys, coatis, birds, or peccaries and carry them on their heads or in baskets.

The forests of eastern Paraguay are dense and hard to traverse. This physical barrier and, until recently, the rather small Paraguayan population, kept the Aché in relative isolation until the mid-twentieth century. Many Aché did not make friendly contact with Paraguayans until the 1970s, and some, including most of the members of our foraging band, came into peaceful contact only in 1978.

The group we work with, known as the Northern Aché, number approximately 300 and now live on a parcel of land called Chupa Pou, or New Camp, provided by the Catholic Church. They are learning how to farm and raise domestic animals, but many still spend a considerable amount of time foraging in the surrounding forests, living in the old way. Although they now possess metal axes, machetes, and knives, the Aché still obtain food in the *monte* by traditional methods, using their hands, bows and arrows, and axes for most hunting and gathering tasks.

While I was still chewing my first *buchu*, Kuaregi declared that there were no more larvae in that tree, and everyone quickly resumed walking. Kuaregi led the way, carrying his bow and arrows in one hand, a machete in the other. He cut an occasional branch or vine, but otherwise wound his way expertly through the undergrowth. After a few minutes Kim and the other five men slipped quietly into t forest to hunt. The women, children, an followed Kuaregi.

We wove our way, single file, throu the forest, squeezing through small ope ings in the vegetation, ducking und vines, climbing over fallen trees. W waded through the waist-deep water of wide, swampy bog and scrambled up t steep, muddy bank on the other side. Tw girls, each about twelve years old, ran to nearby tree and climbed quickly to t spreading branches some forty feet abo the ground. They shook the tree back a forth until a volley of bright orange, w nut-sized fruits peppered the grou around us. A woman handed me a plum juicy fruit and said, "This is *virella.* It very sweet." I tasted it, and though swe the fruit also stung my mouth a little, as it contained a small amount of acid toxin in the fruit or seeds. November is t height of the season for *virella* and also f *pretylla*, a grape-sized red fruit. We a hundreds of these fruits in the next fe days, usually consuming nearly all of the on the spot. A few were gathered and ca ried to the evening's camp.

At times during the day we heard hig pitched calls from the men who were hu ing. Kuaregi or the women would answ and then tell me what had been commu cated: "They have found a peccary trai or, "They are chasing monkeys." I was a tounded by their ability to understand t calls, which seemed to come from a gre distance. Kim estimates that the Aché c call and exchange information over d tances of up to three-fifths of a mile, impressive feat in forests so profusely ve etated that light scarcely penetrates the

As we walked behind Kuaregi—up a down hills, through thick, thorny patch of bamboo, across small milky-color streams—I thought that we had be walking in circles. Convinced of this, I b gan to doubt the accuracy of my compas which indicated that we had hardly de ated from a straight south-southwe course. I realized that although I ha

DODGE CARAVAN
5/50 PROTECTION, STANDARD

UNEQUALED.

GIVE THE PEOPLE WHAT THEY WANT...

Just two short years ago, Dodge Caravan carved a brand new niche in the American automotive marketplace. There was nothing quite like it and there still isn't. It's a combination economy car. Luxury car. Family sedan. Station wagon. And van. Evidently, it's just the right combination, because people keep buying them almost as quickly as we can build them.

HAULS PEOPLE. HAULS CARGO. YOU CAN EVEN SLEEP IN IT.

Caravan has an amazing capacity for people and things. It hauls plenty of cargo. (Up to 125 cubic feet.) Or, depending upon the type of seating you choose, up to eight adults. *Comfortably.* And, if you add the converta-bed that sleeps two, you'll find that Caravan can even become your home away from home.

Caravan measures up nicely on the outside, too. It's a mere 5'4" tall, which makes it easy to step in and out of—or to slip into your garage. And Caravan's actually shorter in length than a full-size station wagon. So it's easy to park, maneuver and handle.

THE ONE AND ONLY WITH 5/50 PROTECTION AND FRONT-WHEEL DRIVE.

Although the success of Caravan has prompted others to jump on the "mini-van" bandwagon, there's still nothing quite like it. No other vehicle of its kind offers front-wheel drive to move you easily through mud, snow and rain. And no other vehicle like it offers a standard 5 year/50,000 mile Protection Plan.* Which means Caravan is *still* at the head of its class.

GET YOUR OWN TRANSPORTATION REVOLUTION.

The revolutionary Caravan. Try one on for size...even buy or lease* your very own at your Dodge dealer. It has a capacity to please that remains unequaled...once again for 1986.

Dodge

BUCKLE UP FOR SAFETY.

spent a lot of time hiking and camping in the United States, my sense of direction failed me in the jungle. The vegetation blocks anything more than about thirty feet away and even makes locating the sun difficult.

On the side of a gently sloping hill we stopped walking and the women took off their *nokos* and sat down. One of them kindled a fire, and then others took burning branches from the blaze and started their own fires. The women often light fires during their frequent rest stops, especially when mosquitoes or other insects are bothersome, because the smoke deters the bugs. These days the Aché have access to matches and lighters, but these niceties are rarely used on foraging trips. The Aché prefer to carry a piece of smoldering wood, which can be used to start a fire much more quickly than can matches or a lighter.

We had been resting for a few minutes when Kuaregi picked up an ax and headed up the hill. "He is going to chop some honey," one of the women told me. At the same time two of the women hefted axes and walked in the opposite direction. "They are going to chop palms," I was told. I got up and followed Kuaregi. He walked a short distance back along the way we had come, then went about thirty feet off the path to the foot of a large hardwood tree, about two feet in diameter. He pointed to a spot some twenty-five feet above us, and I could see a hole through which bees were coming and going. Apparently I had been the only one not to notice the tree when we passed by it earlier. While I was wondering how he was going to reach the hive, Kuaregi began chopping at the base of the tree.

I knew it would take a while to fell the tree, and hearing the sound of axes hard at work from near our resting spot, I left the honey tree to see what the women were doing. I walked toward the sound and found myself thrashing through the brush, getting entangled in vines, crawling through the branches of a fallen tree. I must have sounded like a truck crashing through a fence because when I finally reached an opening, Kuaregi's wife, Kry'ygi, and several children were looking at me and laughing. "It is Kry'ygi [also my Aché name]; he doesn't know how to walk in the forest yet," one young girl giggled. I joined in the laughter. Walking in the jungle is a skill that comes with practice, and even children of five or six years held a great advantage over me.

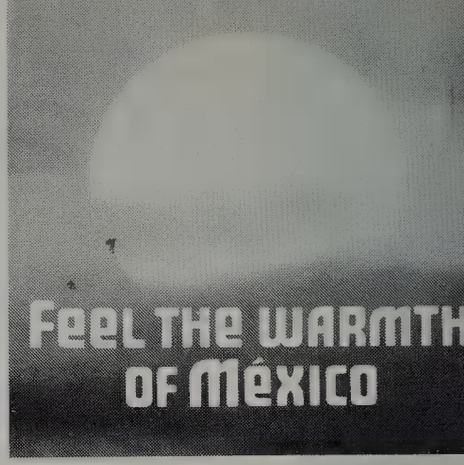
As I brushed myself off, Kry'ygi picked up her ax and resumed chopping. I was taken by the ease with which she handled the ax. The strokes were perfectly placed and came in a smooth, powerful cadence, each blow cleanly slicing free a large chip of the palm wood.

In five minutes Kry'ygi was nearly through the twelve-inch palm. She told the children and me to move out of the way and then, with about six more blows, brought the tree down. She next moved to the crown, pushed back the outer fronds, and chopped at the center. In a few minutes she pulled out an eighteen-inch-long, four-inch-wide white cylinder, the palm heart. She ripped off and discarded a few strips of the stringy material that sheathed it and tossed the heart on the ground near her daughter, who broke off several pieces and offered me one: "This is *tangy*." Cool, moist, and delicious, *tangy* immediately became one of my favorite jungle foods.

Kry'ygi came over to her children and stopped for a minute to play with the baby, who hadn't been pleased to have been left in the care of his sister. She then went back to the tree and chopped a small square "window" through the bark. Flipping the ax over, she pounded the fibrous wood with the blunt end of the axhead. After about a dozen blows she pulled out and sampled a handful of the stringy orange pulp. "It is sweet," she said. Apparently satisfied with the quality of the fiber, which the Aché call *kraku*, she opened a three-foot-long section of the trunk. All in all, Kry'ygi extracted about thirty pounds of *kraku* that day. Most of it was eaten by the women and children at the rest stop by simply placing a large handful in the mouth and sucking on it until the sweetness was gone. Another common way of eating *kraku* is to squeeze the fiber in water and to use the bróth for boiling meat.

I was noisily enjoying my fifth mouthful of *kraku* (eating it is something like sucking on a wet, sweet, frayed hemp rope), when I heard branches cracking, quickly followed by a very loud crash. I had nearly forgotten about Kuaregi and the honey tree. Kuaregi called for someone to bring fire. As one of the women picked up a couple of burning sticks, the children scrambled for all the available pots and containers, and then we hurried toward the tree.

Kuaregi was leaning against the trunk of the fallen tree, taking a short breather after felling the huge hardwood. A few beads of sweat dampened his forehead and upper lip. I noticed this primarily because the Aché perspire very little, whereas I was constantly dripping in the hot, humid climate. The woman who had brought the burning sticks thrust them into a pile of dry leaves and wood that Kuaregi had gathered and blew on them until the mass burst into flames. Kuaregi took a smoldering piece of wood in one

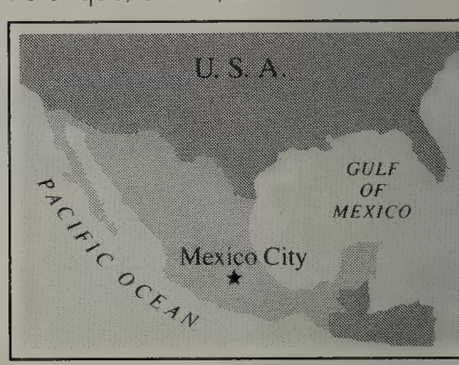


Ask your travel agent for information on the following:

BEACHES Over 6,000 miles of beaches and sunshine year-round. Visit Acapulco, Cancún, Cozumel, Mazatlán, Puerto Vallarta, Manzanillo, Ixtapa-Zihuatanejo, Los Cabos, Loreto, Guaymas.

COLONIAL TOWNS Steeped in history and charm. Visit Guanajuato, San Miguel de Allende, Morelia, Puebla, Cuernavaca, Taxco, Oaxaca, Mérida.

ARCHAEOLOGY The mystery of our ancient cultures in over 11,000 sites. Visit Teotihuacan, Tula, El Tajín, La Venta, Monte Albán, Mitla, Tulum, Palenque, Uxmal, Chichén Itzá.



ARTS & CRAFTS Everything from pottery to silver to hammocks, colorful and alive. Visit Guadalajara, Oaxaca, Pátzcuaro, Mérida, Taxco, Uruapan, Tzintzuntzan, Veracruz.

CUISINE Among the world's most enticing cuisines. Visit Puebla, Oaxaca, Chiapas, Yucatán, Veracruz.

These are a few of Mexico's many attractions, only hours away on over 70 daily flights from major U.S. and Canadian gateway cities.

Dear folks, Mexico is a wonderful dream.
Unspoiled beaches that go on forever.
Natural beauty that's positively breathtaking...
and people like Juan our diving instructor,
who are as warm as the golden sun which shines
every day. Oh, how we're going to hate to leave.

Love,
Sally & Bob & the Family Clown.

Feel THE WARMTH OF MÉXICO.

hand, his ax in the other, and headed for the hive, now only a few feet above the ground and surrounded by a thick, noisy swarm of bees. He rather nonchalantly held the stick near the opening for a few seconds, then laid it on the tree and began chopping. In a manner very similar to the way Kry'ygi had opened the palm tree, he cut a square "window" around the hive opening. He appeared undaunted by the bees, although there were dozens of them on his bare chest, head, and back.

He took more burning sticks and held them over the window, blowing occasionally to direct the smoke into the hole. Bees were now all over him, covering his head and torso like a hooded shirt. He then reached into the tree, pulled out huge chunks of comb, and dropped them on a pallet of leaves that the women had placed on the ground at his feet. He was stung a few times on the hand and arms but not nearly as often as I would have expected.

The women and children gathered the pieces of comb as Kuaregi dropped them and put them in buckets and pans. Some of the pieces were dripping with honey, while others were dry, being either empty or containing only undeveloped bee larvae. Everyone was eating both honey and larvae. Extra honey was put in containers for later use, but the larvae were all consumed on the spot. The honey was eaten by putting a piece of the comb in the mouth, chewing and sucking until only wax was left, and then spitting it out. The larvae were slightly sour-tasting and quite good, while the honey rivaled the best I have ever tasted.

The six quarts of honey not eaten at the tree would be carried to the evening's camp, mixed with water, and drunk. The Aché warned me not to eat too much "straight" honey or I would get a stomach ache. When it was mixed with water, they said, I could drink as much honey as I could hold with no problem.

Honey was in season, and we ate it every day, although it varied in taste. Two kinds came from small, stingless "sweat" bees and were quite sour. Some was from a type of bee so aggressive that when the tree was being opened and the honey taken, the men made the women, children, and me stay at least one hundred feet away.

When all of the honey had been taken from the hive and the pieces of comb stashed away in containers, Kuaregi joined the children in licking and sucking the last of the honey from the leaves it had rested on. Then Kuaregi showed me how to clean up. He found a dry, rotting log, then broke off a chunk, crushed it in his hands, and vigorously rubbed the powdery wood dust on his sticky arms, chest, ar face. I tried it and was delighted to fi that the honey was completely absorb and removed, even from between my fi gers, which had been nearly fused t gether with the sticky substance.

We carried the honey-filled pots ar pans back to our resting spot, where t women packed them away in their *nok* While they were getting ready, Kuare headed off, and we once again began mo ing through the forest, following in sing file. We walked for a couple of hou mostly through thick stands of bamb with needlelike thorns and razor-sha leaves. Just as the light was beginning fade, Kuaregi stopped and began cutti the undergrowth down to ground lev with his machete. This was to be o camp.

He cleared an area about fifteen feet diameter, then each woman went to a d ferent spot along the perimeter of the s and took off her *noko*. The women th headed into the forest to gather firewoo Each collected wood for her own fi around which she and her family wou prepare food, eat, and sleep. They look for dead, dry, partly rotten logs from inches to one foot in diameter and fro three to eight feet long. The fires, one each family, consisted of five to twe pieces of wood extending out from t camp and burning at their converged nermost tips. Following the women's lea I made a fire and cleared sleeping pla for Kim and me.

When we completed camp, the wom sent three older children to get water fr the trickle of a stream that ran in a shall gully about fifty feet from camp. Wh they were gone, Jamo, the grandfath who had been out with the rest of the hu ers, returned. He walked silently i camp, sat down, and picked up a *da peka*, one of the small plaited fans t Aché make for fanning fires and swatti insects. He sat quietly, occasionally sla ping his back with the *dave peka*, and st ing off into the forest. After a few minu two of his grandchildren went to him a began searching his body for ticks, specting his back, neck, and armpits. remained silent and no one spoke to hi After about ten minutes he said, "Ther no meat." Everyone was disappointed. I spite having had palm beetle larvae, pa heart and fiber, two kinds of fruit, and l larvae and honey, I was hungry, and parently so was everyone else. Minu later we heard Kim and two of the m just outside camp. The Aché m stopped, leaned their bows and arro against a tree, and each dropped a sm bundle from his shoulders. Two boys

BUY A KODAK CAROUSEL® PROJECTOR NOW AND SAVE UP TO $100 ON THE FRIENDLY SKIES.

If you've been wondering how your slides would look as large and bright as life, now's the time to find out. Buy a Kodak Carousel projector between Sept 1 and Dec 31, 1985, and we'll give you a fare deal on a United Airlines trip anywhere in the U.S.A.

Choose a model 5200 or 5600 Carousel projector and get a certificate worth $100 off on two United Airlines tickets ($50 off each ticket). Or buy one of our 4000-series models and get a certificate worth $50 off on a single United Airlines ticket.

There's never been a better time to buy a Carousel projector. Or better reasons.

You'll finally be able to enjoy your slides the way they were meant to be seen. To relive your most memorable experiences with breathtaking realism.

Get off to a flying start. See details below, or ask your participating dealer.

Each individual named on a valid certificate is entitled to a $50 discount toward the purchase of a round-trip ticket wholly on United Airlines scheduled service between U.S. points. In the case of the $100 certificates, tickets for both individuals named on the certificate must be purchased at the same time, although different itineraries are allowable. ■ To make your claim, you must submit your name and address, the name of each person as it is to appear on the discount certificate(s), the original dated sales receipt, and proof of purchase in the form of the Part Number area cut off the back of the projector instruction manual. ■ Once this has been submitted, allow a minimum of 30 days for processing and return mail. ■ **Tickets may be purchased from October 1, 1985, through April 30, 1986. Travel is valid from December 1, 1985, through November 30, 1986, with the following exceptions: December 18-22, 1985; December 26-31, 1985; March 27-April 1, 1986; November 23-30, 1986.** ■ Discount certificates are not refundable, cannot be combined with other United Airlines promotional discount offers, and can be redeemed only by the individual(s) named on the certificate.

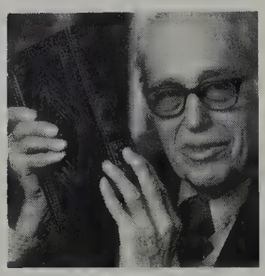
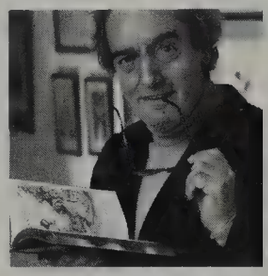
We asked these three experts to put a price on this edition of Dickens' DAVID COPPERFIELD. $12.50



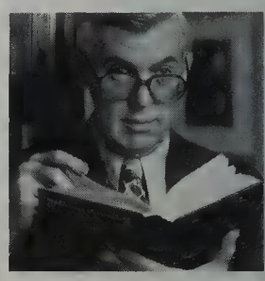
"The raised spine is a giveaway. That's quality binding. **$30."**

KEN McCORMICK,
Sr. Consulting Editor,
Doubleday.



"The illustrations are superb. Excellent typography. **$35."**

CLIVE BARNES,
Cultural critic, New York Post



"The paper is fine mill The end pages an unusual design. A first class job. **$35."**

PHILIP LYMAN,
Gotham Book Mart.

WRONG. WRONG. WRONG

The price, of course, is only $12.50 for *David Copperfield* and every other volume of the new Collector's Library of the World's Great Books.

Again and again, Franklin Library, the world's leading publisher of fine books, has seen its remarkable new Collector's Library confound the experts.

How can these authorities be so right in their praise and so wrong in the price?

Let's take a close look and see why.

Each of the fifty volumes is individually designed; each cover is a work of art, each binding distinct in size, grain, color.

(The effect in your room is unca Each volume different but harmoniou luxurious library that is a tribute to y taste.)

Each spine is hubbed in the gre dition of book binding.

Each endsheet (inside covers) is original design.

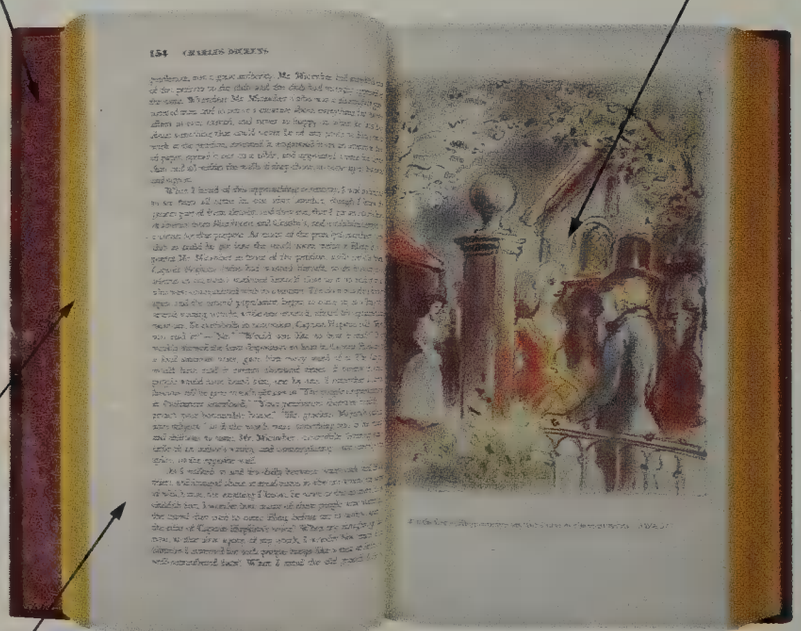
The page edges are gilded; the paper, itself, is crisp, opaque, specia milled and acid free to last for gener tions.

Many artists were commissione the project. And the illustrations are nificent. (The color paintings by Tho Rowlandson in TOM JONES make u gle with pleasure.)

Distinctive endpapers, specially designed for the collection, and varied among the volumes.

Superb illustrations, many specially commissioned, including a number in full color.

Each binding is individu designed: the copper c dies are hand finished.



Hubbing—a valued characteristic of the traditional bookbinder's art.

Page edges gilded with a tarnish-free finish for both protection and beauty.

Specially milled, acid-free paper that will endure for generations.

How did we do it?

he typography is classic, the print-
t rate, the contents immortal and
ss.
et the price for each volume is only
, less, as you know, than ordinary
ver books.
is a publishing conundrum with a
albeit spectacular answer.
n Library has made a publishing
nrough of which it is very proud.
ere is the genius of mankind.
ternal classics, from Homer's
SEY to Melville's MOBY DICK.
ne chilling tales of Edgar Allan
he romance of Emily Bronte's
IERING HEIGHTS. The earthy
of CANTERBURY TALES by
Chaucer. The transcendent dramas of Shakespeare (illustrated by Henry Fuseli), Ibsen, Chekhov. Great English and American poetry.

Fifty volumes in all. A library of genius that belongs in every home.

Here is adventure for the mind, for yourself and for your children. Inspiration and pleasure more abiding than television, more memorable than movies. At a price that makes it almost mandatory. (And *that* is Franklin Library's intention.)

Subscribe without risk.

As a subscriber, you build your collection one book each month, and payment is on the same convenient basis. The subscription price is a remarkable $12.50 per volume.

A *guaranteed* price, if your subscription is mailed by December 31, 1985. You need send no payment now.

You may cancel your subscription at any time, upon 30 days' written notice, and return any book for any reason, within 30 days.

The Collector's Library of the world's great books.
A revolution in publishing.

Aché women and children begin a trek into the forest. The women carry large burden bags called nokos.

ting by me exchanged excited grins but remained silent.

The men ambled into camp and quietly sat down, as had Jamo. One of them motioned to his son, a boy sitting by me, to go over to the bundles. The boy jumped up and he and a friend ran to the spot. They returned beaming, one carrying a large adult female armadillo and one of her young; the other, two capuchin monkeys. We would not go hungry tonight after all.

Kim came over to our fire and sat down. He looked horrible. He had been stung four or five times by wasps and one eye was swollen shut. Small wasp nests in the vegetation were very active at this time of the year, and we all got stung several times a day. Kim's encounter was by far the worst of the entire band so far and reflected the higher risk of injury hunters take by running through the thick forest. The women and I picked our way through the brush and looked out for each other, but the men could not afford such luxuries, and were much more vulnerable to stings, snakebites, and even jaguar attacks. Luckily, the stings were not from the wasp the Aché call *cue'e pura*, whose sting allegedly causes nausea, difficulty in breathing, and sometimes a lapse into deep sleep—classic symptoms of allergic shock.

The Aché immediately began preparing the meal. The hair was singed off the monkeys, which were then cut up and placed in pots to boil. The armadillos were gutted, and the tail and internal organs were placed in the fire, then eaten as appetizers. Either men or women may cook meat, although a hunter will rarely cook and distribute game that he has killed.

While the meat was cooking the two remaining hunters strode into camp, carrying a baby jaguar they had killed. While tracking peccaries, they had apparently come upon a female jaguar and her cub feeding on a freshly killed peccary. The adult jaguar fled, but the cub ran up a tree and was killed by the hunters. The men also brought what was left of the peccary back to camp with them. There would be plenty of meat tonight.

The baby jaguar was a beautiful animal, and I felt more than a twinge of uneasiness when I saw it being carried into camp, and even more when I actually ate the animal (it was light, tender, juicy, and very tasty). Jaguars are, of course, an endangered species. The Aché, however, have no remorse about killing them and take every opportunity to do so. They look upon jaguars as fierce predators. Kim was with a group of Aché several years ago when a jaguar was heard circling camp in the middle of the night. Women and children huddled crying in the middle of the camp while the men took bows and arrow and stood ready to fend off an attack which fortunately never came. Lone Ach hunters are sometimes attacked by jag uars, and many have been killed by th cats. The father of one of the men in ou party was killed when he was dragge from the camp by a jaguar in the middl of the night as the others looked on. Still, wished that they hadn't killed the cub.

I wished it even more strongly whe Jamo, the grandfather (all old men ar called Jamo, which means, roughl "grandfather" but also means "jaguar" berated the hunters for killing the jagua and bringing it back to camp. "Th mother will be angry and will go lookin for her baby," he said. "She will smell here and come into our camp."

Once, in the middle of the night, w heard some noises in the forest, and th men sat up and listened intently before l ing back down to sleep. I was scared, but felt secure knowing that the Aché wer keeping watch. I was also very tired fro the long day and slept soundly. There wer no further noises, but in the morning, th men found fresh jaguar tracks nearby.

We spent another six days in the fore before walking back to Chupa Pou, ou notebooks full of information on the food collected by the Aché and the time spe searching for and processing them. W also collected data on child care, th butchering of game, and the discard bones and other refuse.

We are particularly interested in th Aché because they still practice huntin and gathering, as did all of our ancesto for most of the evolutionary past of our g nus. We have focused on their ecology an attempt to learn about the ways peop with simple technology cope with the environments. And although our emph sis is on quantitative data collection, th has not kept us from establishing clos friendships.

One of the bonuses of anthropologic fieldwork is the opportunity to meet an live with people like the Aché. Since w have returned from the field, our co versations have not been about the seve ity of the living conditions in the forest even about the strange foods we ate, b about the Aché themselves—their curio ity, humor, strength, and knowledge of th forest and the good times we shared. M Thanksgiving Day in the *monte* was one the best.

Kevin T. Jones is a research assista professor of anthropology and partic pant in the Hunter-Gatherer Researc Group at the University of Utah in Sa Lake City.

NURTURE YOUR COLLECTING INSTINCTS AT THE POST OFFICE.

Bring home this shy ppaloosa filly.
And the Quarter rse. And the Morgan.
Or ride off with the ddlebred.
They will carry you o a lifetime of pleasure seeking and finding stamps that define who you e. Of creativity—organizing them in your own particular style. Of deep personal moments that are much larger than the stamps themselves.

So let these beautiful horses give you a nudge in the right direction. To the Post Office. And into the gratifying, growing world of stamp collecting.

Geoffroy and the Homeobox

The art of finding timeless essences in apparent trifles is the kind of perception that we call genius

by Stephen Jay Gould

As Dickens said about another moment in French history, July 1830 was both the best and the worst of times. From July 27 to 29, known ever since to Frenchmen as *les trois glorieuses,* citizens manned the barricades in Paris and finally forced the abdication of despotic Charles X, younger brother of Louis XVIII. On July 31, on the balcony of the Hôtel de Ville, the aging marquis de Lafayette, America's friend in previous times of trouble, draped himself in the tricolor banner, embraced the duc d'Orléans, and proclaimed him Louis-Philippe, the new, *constitutional* monarch of France.

In the midst of this upheaval, a noted German observer wrote with brimming enthusiasm about a great Parisian battle: "We find in conflict here two such different ways of thinking . . . . It has often happened before in the history of this antagonism, and the phenomenon must occur again and again. . . . When such different elements are forced into contact, where they touch, every time an explosion must result."

The observer, we assume, must have been writing about the age-old strife of monarchists and republicans, then playing its latest version on the streets of Paris. He was not. He described, in these dispatches, an argument then raging in l'Académie des Sciences—"of such great importance," he wrote, "that the history of science may never experience a second example."

The debate, running throughout 1830 in and around the July revolution, featured France's two greatest zoologists as adversaries: Georges Cuvier and Etienne Geoffroy Saint-Hilaire. The observer was no mean journalist: Johann Wolfgang von Goethe. Geoffroy's son, writing later about the great debate, spoke of Goethe's involvement:

> At the very dawn of events that would overthrow a throne and change the face of France, he immersed himself in this peaceful revolution occurring in the pure realm of ideas.

Goethe was no incidental bystander, roped in on a lark. The great poet was also a fine scientist, a student of organic form, and inventor, incidentally, of the word *morphology.* He was also a partisan of Geoffroy's side in the great debate.

This famous struggle, often portrayed quite wrongly as a debate about evolution (which Cuvier opposed to the core and Geoffroy supported in a fitful way), began as an argument about anatomy and ended as an unresolvable conflict between the two most general and irreconcilable attitudes about the nature of organic form.

Geoffroy, a romantic and a dreamer, had a vision—perhaps the boldest, the most noble, the most comprehensive idea ever promoted in biology. As a *pure* morphologist, he sought nature's order in a single abstract plan for all organic design. He maintained, virtually as a motto, "There is, philosophically speaking, only a single animal." (Cuvier, as a *functional* morphologist, denied the utility or reality of such abstractions and argued that an irreducible diversity of form matches the particular functions that organisms perform.)

Goethe hoped against hope that Geoffroy could beat the silver-tongued Cuvier, one of France's greatest orators. For Goethe shared Geoffroy's vision and had, himself, advanced for plants the same general argument that Geoffroy now a vocated for animals.

Goethe's idealistic morphology plants, proposed late in the eighteer century, tried to understand the vari parts, particularly the diverse structu of flowers, by conceiving them as so ma expressions of one underlying, abstra theme that could generate all existing p ticulars through a set of geometrical tra formations. For Goethe, this ideal sou was the leaf itself.

Geoffroy applied the same vision to a mals, arguing that vertebrae could p form for moving things the same role t Goethe ascribed to leaves as the foun tion of form in plants. The dream that apparently overwhelming diversity mig be reduced to one underlying generality a foundation sought not in the mechani terms of physics and chemistry but in ideal realm of pure form—motivated b men.

But scientific visions, no matter how ble, are only as good as their evidence and Geoffroy proposed an elaborate se hypotheses to affirm his claim that a mals are built as repeated and modif vertebrae. He sought to establish a hom ogy—that is, a true similarity based common origin, rather than a mere an ogy or likeness developed independen by two groups in response to shared fu tional needs—between the complete s mentation of insects and the partial re tition of vertebrates (seen primarily in vertebral column and paired ribs).

Such a proposed homology between segments of an insect's *external* skele and a vertebrate's *internal* spine lead some mighty peculiar comparisons, if

pledge to follow the basic model in a forthright and rigorous way—as Geoffroy certainly did. He wrote in 1822, with a firm assurance that others will interpret as bold or foolhardy according to their prejudices:

> I have never ceased to follow nature's great thought: the unity of organic composition; and, in the confidence that this fundamental truth has given me, I must grasp my problem in its greatest generality, approaching each part not with hesitation, but moving on the contrary with sureness.

Two comparisons, particular, struck most biologists as especially hard to swallow and helped to seal Geoffroy's fate. First, if the bones of a vertebrate's spine are homologous with external segments of insects, then insects must—quite literally—live *within* their own vertebrae. Geoffroy wrote in 1822: "Every animal lives outside or inside its vertebral column" (*Tout animal habite en dehors ou en dedans de sa colonne vertébrale*). Second, if the paired attachments to all "vertebrae" are also homologous, then the legs of insects are the same structures as the ribs of vertebrates—and insects walk on their ribs.

Since pictures are so often worth the proverbial thousand words, consider as an expression of Geoffroy's bona fides his illustration of a lobster's segment, published in 1822. Note the subtle positioning and proportions that make the lobster's external girdle look so much like a large vertebra with a substantial hole in its center for living tissue, while the legs bend and begin to wrap forward like a pair of vertebral ribs.

The comparison of insect and vertebrate caused difficulty enough for Geoffroy's vision of organic unity. But he wanted more and went further, provoking Cuvier's ire and his own downfall. Early in 1830, two of Geoffroy's young disciples tried to extend the grand homology by arguing that cephalopods (squids and their allies) are built as vertebrates doubled back on themselves, thus bringing the great phylum of mollusks (including such overtly unsegmented creatures as clams and snails) into line with arthropods and vertebrates.

This was too much for Cuvier, the pre-eminent functionalist who understo that the strong similarities between squ and fish were analogies independen built as good, hydrodynamic solutions the problems of swimming. The great bate had begun.

Goethe, from the sidelines, rooted Geoffroy, but most observers scored t match as a decided victory for Cuvier though debates of such abstraction are simply "won" or "lost" in conventio terms). And so history has judged this rious event. In our current classificatio complex animals are divided into two m jor branches, the protostomes (includi insects) and the deuterostomes (includi vertebrates)—and never the twain sh meet. As a graduate student in system ics twenty years ago, I learned no tru with greater assurance than the propo tion, proved by Cuvier against Geoffr that the full and complete segmentation arthropods has no homology with the li ited and imperfect segmentation of ver brates, confined primarily to muscles the trunk and their associated skeletal a nervous systems. Geoffroy's vision unity in organic design died 150 years a

But big ideas developed by great thi ers rarely disappear completely. Few m of vision are so profoundly wrong that motivating dream of an intellectual li time contains nothing worthy of later tention, often in an intriguingly alte form. Sure enough, last year's bigg news in developmental genetics exhum Geoffroy's old vision of homology tween the segmentation of arthropods a vertebrates (although I have been ast ished that no one, in scores of primary a cles and secondary reports devoted to subject of the so-called homeobox, drawn the obvious connection with Ge froy's ancient vision). The story, as shall see, is particularly interesting cause a superficial interpretation of "homeobox" revives Geoffroy's dream its overt form. We shall see, however, t this interpretation cannot stand—but t victory may yet be snatched from th jaws of Geoffroy's second defeat to aff something deeper about his curious, profound, vision.

In the fruit fly *Drosophila,* best kno

angosta del Pacífico. Pacific lobster with mayonnaise.

Ajiaco. Chicken stew with potato, corn and capers.

Bife de Chorizo. Broiled Argentine beef served with Chimichurri sauce. (Parsley, garlic and oil.)

EASTERN AND THE AMERICAN EXPRESS® CARD CAN HELP YOU SAVOR SOUTH AMERICA.

In South America, the local cuisines are as fascinating to xplore as the local scenery.

In fact, the food is so appealing, you may think the old dage "travel is broadening" refers to your waistline as well as our mind.

But never fear. In South America, you an work off the pounds by hiking to see he ruins, touring cities filled with master- ieces of baroque architecture, jogging long sandy beaches, skiing down the world's highest slopes and dancing to the beat of a tango.

And because of Eastern, you won't have to spend as much money as you think.

Eastern can fly you to Argentina, Chile, Paraguay, Bolivia, Colombia and Ecuador in South America. As well as to Mexico, Guatemala, Panama and Costa Rica. In fact, to more of Latin America from more of North America than any other airline. With packages that make your vacation affordable.

For more facts, see Eastern or your Travel Agent.

And be sure to charge your South American trip with the American Express® Card—which is welcomed almost everywhere. Use it for shopping, nightclubbing and dining in fine restaurants. It shows you have terrific taste. Don't leave home without it.®

With Eastern and the American Express Card, you can enjoy a vacation that's fulfilling in every way.

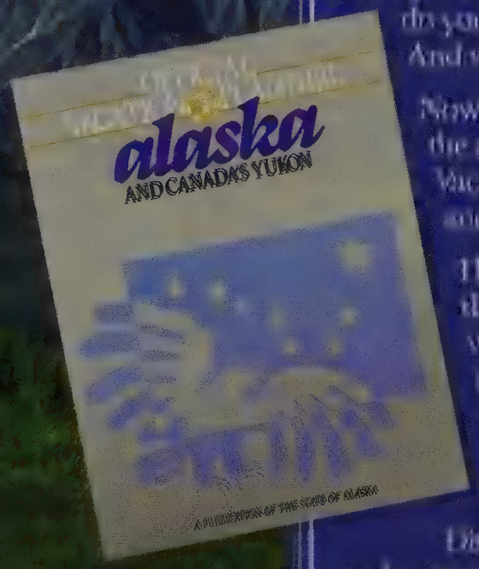
of all complex animals in genetic term differentiation of segments (why some d velop mouthparts, others wings and leg still others abdominal structures) falls u der the control of two gene complexes l cated on the right arm of the third chr mosome. Each complex contains sever genes. The antennapedia complex (calle ANT-C for short) influences anterior se ments of the head and thorax, while the b thorax complex (BX-C) works upon th fly's rear end, from the back part of th thorax through the numerous abdomin segments. Well-known mutations in se eral of these genes have the peculiar pro erty of placing normal structures in th wrong places. (In the namesakes of th two complexes, flies with the *antenn pedia* mutant grow legs where their ante nae should be, while *bithorax* individua develop a second pair of wings in oppo tion to their own name—flies are Dipter or two-winged.) Such mutations, repla ing expected organs with homologo parts that should develop in other place are called homeotic, a term coined early the century by William Bateson, who al gave genetics its name. (See my column October 1980 for more information homeotic mutations.)

Early in 1984, molecular geneticists a nounced a remarkable discovery abo the fine structure of three genes in the homeotic complexes. We are living in t midst of a revolution in technique with genetics that is spilling into public atte tion via debates about genetic enginee ing. The methods of research in so-call recombinant DNA have permitted us learn, in a routine way, albeit with a va amount of hard work, the sequence base pairs that builds the genetic mater of DNA. We can, in other words, now re the detailed structure of genes.

A very short region, only 180 base pa long and located within the *antennaped* gene, showed such remarkable similari to a unit of identical length in anoth gene of the antennapedia complex (call *fushi tarazu,* or "futz," for short, amo the cognoscenti) that both must share common evolutionary origin—the simila ities are too complex and detailed for ind pendent evolution under similar co straints of function (see my column April 1985 for an explicit discussion when and why detailed molecular simil ity must record homology, or unity of ev lutionary origin). Soon afterward t same short sequence was detected in gene of the other homeotic complex, *trabithorax* of BX-C.

This short, highly conserved sequen received the name homeobox because was first found only in genes of t

100 Pages of Free Advice for Anyone Wishing to Experience the Vacation of a Lifetime.



Alaska. Where do you begin to explore its 586,400 square miles of timeless beauty? How do you get around? Where do you stay? How do you dress? And what do you do?

Now there is a book that provides the answers. It's the 1980 Official Vacation Planner for Alaska and Canada's Yukon.

The beautiful publication of the State of Alaska is filled with all kinds of advice, facts, figures, maps, information and color photographs. It's a must for anyone going to Alaska. And it's free.

A L A S K A

homeotic complexes and because its trim, tight composition of but 180 base pairs suggested a discrete unit (a "cassette," as one discoverer wrote) that might be copied precisely and inserted into various parts of an organism's genetic material.

This discovery provoked a search for other copies of the homeobox within *Drosophila* genes. The work continues, but a recent report (a review by W.J. Gehring in *Cell,* January 1985, pp. 3–5) mentions more than ten additional genes containing homeoboxes. The homeotic complexes have emerged as preferred "homes" for this conserved sequence—five genes of ANT-C, and three within BX-C, contain homeoboxes. The copies found outside the homeotic complexes lie in genes that also seem to code for some aspects of spatial organization in the embryonic segments.

The homeobox first inspired excitement because it seemed to confirm a long-standing hypothesis about the evolutionary origin of the homeotic complexes. Ed Lewis of CalTech, world's expert on the homeotic genes of *Drosophila,* had proposed that the many genes of BX-C (at least eight), arrayed in linear sequence along the right arm of the third chromosome, arose as repetitions of a single ancestral gene (see my column of November 1981 on the ability of some genes to make copies of themselves and move to new positions). The presence of such a highly conserved, shared sequence within so many homeotic genes provides strong support for Lewis's theory (an alternative, or complementary, idea might hold that only the homeobox cassette duplicates and inserts itself in new places).

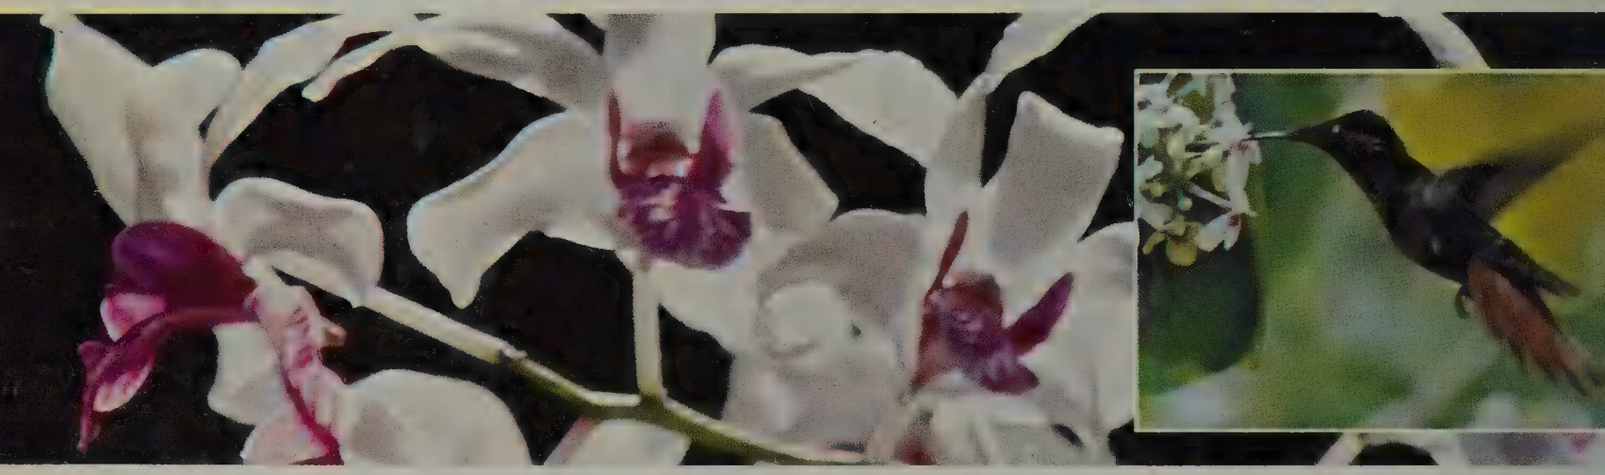
The simple existence of such a highly conserved sequence in so many places provided enough excitement, but the story goes deeper—thus forging the link to Geoffroy's old vision. (I should say at the outset of this linear account of events that I am not describing discoveries in their chronological order but in a logical sequence of my own construction that allows me to make sense of much fine work, proceeding in several laboratories and cascading simultaneously in many directions. All these discoveries occurred or were published during 1984—a good sign of how quickly an exciting field can move.)

The presence of so many copies throughout the *Drosophila* genome does not prove that the homeobox does anything important for the organism (some repeated elements may act as "selfish DNA," able to replicate, move, and insert, but performing no function for the larger organism containing them—again, see column of November 1981). An argum for function must first determine whet or not the homeobox gets transcribed i RNA and then translated to protein or zyme—and the link to Geoffroy's vis requires a hypothesis of function. Mu DNA is silent, or untranscribed, much may be junk (so called) with ref ence to its utility for organisms.

The homeobox is, in fact, transcrib and translated—so this basic argum for function holds. Since DNA is a trip code, the 180 base pairs of the homeob produce a so-called homeodomain of amino acids. The strongest argument important function rests upon the disc ery that this homeodomain (the 60 am acids) is even more highly conserved th the parent homeobox (the 180 base pa of DNA). The foregoing statement m seem puzzling—that higher amino a than code similarity indicates functio meaning for a stretch of DNA—but justification arises from the nature of DNA code.

The genetic code is, in technical p lance, "redundant" at the third positio most cases—that is, the first two b pairs of any triplet determine the am acid that will be translated, while the th

TRINIDAD & TOBAGO Discover a world the world hasn't discovered



In Trinidad & Tobago, you can have a bird in the hand, two in the bush, and a Picoplat in a zaboca pear tree. Not to mention over 400 other bird species that are yours for the watching in our lush tropical sanctuaries.

Our Caroni Bird Sanctuary boasts 150 species of bird. You'll see the legendary Scarlet Ibis fly in at dusk to roost in this vast area of mangrove and marshland. And our Asa Wright Nature Centre hosts the world's most accessible colony of Oilbirds—the only nocturnal fruit-eating bird in the world. Tobago shelters 106 bird species, including the only nesting colony of the Frigate Bird in the Southern Caribbean. The Tropic Bird, Noddy and Booby terns are indigenous to Tobago's Bird of Paradise Island.

If you're a butterfly lover, there are 622 spectacular species to be seen here. And if plants are your fancy, the Botanic Gardens in Trinidad & Tobago offer two charming wonderlands of tropical and subtropical plants. You can wander down our many nature trails, guided by a local nature society.

Venture out in a glass-bottomed boat to our famous Buccoo Reef, a natural aquarium of tropical fish an breathtaking coral gardens. You may even follow in the footsteps of Friedrich Guppy, who first identifie and named the common guppy rig here in Trinidad & Tobago.

So come and discover the nature of Trinidad & Tobago—a world the world hasn't discovered.

Fly BWIA International

TRINIDAD & TOBA

Come discover a world the world hasn't discovered.

tion can often be occupied by any of possible base pairs and still yield the e amino acid in translation. Thus, any ation at the first or second position will se the translation of an altered amino l, but third-position mutations are usu- "silent" because they induce no nge in the product—the amino acid— the organism sees and uses.

Now, the homeodomain is substantially e similar among its several copies than homeobox that codes for it (for the copies discovered in *Drosophila,* ho- box similarities ranged between 75 79 percent of base pairs, while homeo- ain conservation rose to 87 percent of no acids). The basis of this difference t be—and indeed is, as we now know n direct sequencing of the base pairs amino acids—that many silent muta- s accumulate among the different ies of the homeobox to drive their over- similarity down, but that something is tly conserving the amino acid se- nces by rejecting first- and second-po- n mutations that change the structure function of proteins but permitting "invisible" silent mutations to accu- ate in third positions. That something t be natural selection, operating to serve the protein structure of the ho- domain. If natural selection is work- so assiduously to conserve the homeo- ain, then its protein must be doing ething right for the organism—it t, in other words, perform an impor- t function. (The comparison of silent us translated mutations is a standard for function in molecular genetics, not w argument developed for the homeo- story.)

Thus, we know that the homeobox oc- s in several *Drosophila* genes, mostly he homeotic complexes, and that it es for a protein with important func- s. But what does this protein do? At t glance—but please remember that t glances can be dangerously simplis- —we might be tempted to conjecture t the homeobox is a key to the control l expression of segmentation. Why else uld its copies lie in genes of the home- complexes and rarely elsewhere?

We might gain further clues about ction of the homeobox by scanning er organisms to see where it does and s not occur. Initial results on other in- tebrates might be viewed as enhancing suspicion that homeoboxes are regula- s of segmentation. The homeobox se- nce has been found in other species of *osophila,* in *Tenebrio molitor* (a bee- , and in an earthworm of the genus *mbricius*—all segmented animals. It not been detected in a nematode, a sea

CHINA

Stay in the best hotels on the best-selling tours.

Only Pacific Delight, number one to China and the Orient, offers China's leading luxury hotels on every one of its best-selling tours in 1986. All at unbeatable value. Choose among 23 different fully-escorted itineraries, 17 to 25 days, with frequent weekly departures. All visit the must-see Golden Route cities. Then you may cruise the Yangtze or journey to Tibet. Venture on to other Asian capitals, or to Russia on a round-the-world adventure. Send for our 1986 China Experience® brochure with complete details. Then talk to your travel agent.

urchin, and the bacterium *E. coli,* all unsegmented creatures (see W. McGinnis and others, *Cell,* vol. 37, 1984, pp. 403–8).

But the biggest surprise, and the source of popular appeal for the homeobox, arrived with its discovery in yet another group of organisms—our own. If *Drosophila* is the standard invertebrate of laboratories throughout the world, the South American toad *Xenopus* has been granted this dubious distinction among cold-blooded vertebrates (mice play the part for mammals). Inevitably, geneticists turned their search for homeoboxes upon *Xenopus*—with success. Homeoboxes have been found, so far, in two *Xenopus* genes. (Our knowledge of vertebrate development is so poor that we do not know, for certain, how any single gene operates to regulate the position or differentiation of structures in embryology. But we have some pitifully preliminary hints that the homeobox-containing genes of *Xenopus* may play some role in development. One gene, for example, produces RNA transcripts in egg cells and again at the crucial stage of gastrulation in early embryology—where the transcripts might be translated to proteins involved in the determination of embryonic cell types. (See Müller and others, *Cell,* vol. 39, 1984, pp. 157–62.)

The similarity between these *Xenopus* homeoboxes and those discovered earlier in *Drosophila* is startling. The homeodomain of one *Xenopus* gene is identical to the corresponding homeodomain of *antennapedia* in *Drosophila* at fifty-nine of sixty amino acid positions! This frog–fly concordance is far stronger than the similarity between the two frog homeodomains (fifty-four of sixty amino acids, with twenty-three silent third-position mutations in addition), or between any pair of homeodomains within *Drosophila.* Something is working awfully hard to conserve this similarity across one of the most profound phylogenetic gaps in the history of life (the common ancestry of insect and vertebrate predates the establishment of our adequate fossil record in the Cambrian explosion nearly 600 million years ago).

Further scrutiny then revealed homeoboxes in other vertebrate genes. A gene on mouse chromosome 6 contains a homeobox with a 66 to 70 percent base pair similarity to *Drosophila* and 66 percent to *Xenopus* (W. McGinnis and others, *Cell,* vol. 38, 1984, pp. 75–80). Two human genes also sport homeoboxes, yielding an average of 90 percent amino acid similarity with the three homeodomains first discovered in *Drosophila* (see Levine and others, *Cell,* vol. 38, 1984, pp. 667–73).

As discovery cascaded upon discovery many scientists and commentators aske what common theme lay behind these ob viously interrelated observations. An in triguing possibility inevitably bubble forth: homeoboxes are primarily found i genes that regulate the differentiation o segments in *Drosophila;* they are als present in other segmented invertebrate and absent from unsegmented creature Vertebrates also have homeoboxes and a least some form of imperfect segmenta tion. Of course, we had all learned tha segmentation in insects and vertebrate can only be analogous—a product of inde pendent evolution in lineages long sepa rate. Or must segmentation be only anal gous? Could it possibly be homologou after all? The homeoboxes of insects an vertebrates are clearly homologous. they regulate segmentation . . . well, the by God, could Geoffroy have been righ all along and after all (following 150 yea of calumny and the kind of dismissal tha so erased his name from the history of sc ence that not a single geneticist remem bered this link with the past while so man discussed the potential homology of seg mentation)?

Press reports poured forth. Some bega to speak, in overblown terms, about th Rosetta stone of development, biology greatest mystery. Scientists tended to b more cautious, but several floated the h retical idea of homology for the segment tion of insects and vertebrates—Geo froy's common ground plan of anim development. W. McGinnis and co leagues wrote, for example (*Cell,* vol. 3 1984, p. 679):

> If the conserved homeodomain in fruit flie frogs, mice and humans is involved in th control of segmental development, then it possible that the segmentally organized an mals in both the protostome and deuter stome classes had a common ancestor, an that the metameric body plan has evolve only once in metazoa. [Metamerism refe to the complete segmentation of arthr pods; metazoa are the multicellular an mals.]

This explicit vindication of Geoffroy r mains a possible interpretation of the h meobox, but proper caution has begun replace overextended enthusiasm, an other less flashy (but in many ways mo intriguing)—and, I suspect, more prob ble—explanations have now been offere

The superficial interpretation—if it's homeotic genes and homeotic genes reg late segments, then it must regulate se ments—is logically flawed, in fact one the classically false syllogisms of bas courses. We might as well argue th sneakers produce a high field-goal pe

We're often asked why a Leica produces such superior photographs.

The answers may surprise you.

It is generally conceded, by professionals and serious amateurs alike, that Leica® cameras produce superior photographs. Photographs more vibrant, more alive, more three-dimensional than other photographs.

So it is tempting to say that this is simply because Leica produces superior cameras.

Which is true, of course. But hardly a complete explanation.

Because it is only when you fully understand the depth of our commitment to perfection that you can truly appreciate our extraordinary cameras.

Ten tons of glass.

Leica lenses are famous. The world's finest. So it won't surprise you to learn that we ourselves make the optical glass for them.

What will surprise you is how much glass it takes. And how few lenses we end up with.

Every year, our scientists use over ten tons of raw glass. Mixing and melting special formulations in pure platinum crucibles. Refining glass to ultimate optical standards. Discarding what others would consider acceptable. Scrutinizing every finished lens individually. Making sure it combines high color saturation with delicate color differentiation and unexcelled sharpness. Making sure it is perfect.

Ten tons of glass to make a few thousand lenses. No wonder no other manufacturer dares try to imitate us.

Never plastic.

And the mechanical components of our lenses are made just as exactingly. Critical moving parts are brass and aluminum, never plastic. Lens helixes are lapped to ten-micron tolerances, then polished by hand with jeweler's rouge. Thus eliminating the need for heavy greases used by other manufacturers. Greases which can affect focusing performance.

Body talk.

Which leads us to another surprise. Leica camera bodies are not designed and built just to enhance Leica lens performance. They're designed and built to enhance yours.

Again, take focusing. Focusing depends on the photographer's ability to see the image. So we've built the brightest viewfinder possible. Using silver instead of aluminum coatings on our prism. And seventeen dichroic coatings on our primary SLR mirror. To reflect maximum undistorted light.

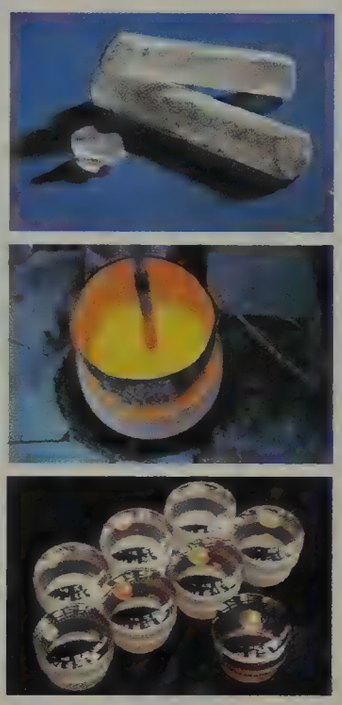
And for creative freedom, we've put an SLR exposure control at your fingertips. So you can switch instantly from manual or aperture priority with spot metering to program, shutter, or aperture priority with full scene integration.

The art beyond the science.

There are hundreds more examples we could give of Leitz's technical accomplishments. Of the specific superiority of Leica design and manufacture.

But at the very highest reaches of any discipline, there are areas beyond mere rational explanation.

And at Leitz,® a camera is more than just metal and glass and tests and formulations. It is pride and integrity and an almost fanatical dedication to perfection. It is skills and secrets passed on from father to son. From generation to generation.



At Leitz, camera making is an art beyond a science.

But that shouldn't surprise you.

After all, so is photography.

For further information about Leica cameras call 1-800-223-0514 or write E. Leitz, Inc. 24 Link Drive Rockleigh, NJ 07647.

Leitz means precision. Worldwide.

Leitz and Leica are registered trademarks of E. Leitz, Inc.

BELIZE

A NATURALIST'S QUEST

Lush tropical forest, Maya mountains, pine savannahs, mangrove swamps and the great barrier reef of the Caribbean - this is Belize, a land of natural wonders and ecological diversity that nurtured the magnificent Maya culture. Teeming with wildlife, Belize supports over 500 species of exotic birds, 250 varieties of orchids, and is one of the last strongholds of the elusive Jaguar. Belize offers the traveler an unprecedented opportunity to experience a wealth of tropical environments.

centage because all great basketball players wear them.

Sure, the homeobox performs an important function, and (from the genes chosen as bedfellows) it probably has something to do with the embryology of spatial organization. But why should that something be the actual control of segmentation itself (the only argument that would affirm Geoffroy's vision in its explicit form)? Think of the more basic activities that genes must superintend before we can even talk about such overt morphological phenomena as segmentation (just as basketball players have to cover their feet with something before they can display any fancy artistry with drives and jump shots)—particularly the production of proteins in the right places, at the right times, and in the right amounts. Perhaps the homeobox works for one of these deeply basic functions acting as a vital prerequisite for anything so much later (in a causal chain) and so much more specific as segmentation.

My friends Elizabeth C. and Rudolf A. Raff (*Nature,* vol. 313, 1985, p. 185) have suggested such a more general and more "mundane" (their word) function for the homeobox. Translation of RNA to proteins occurs in the cytoplasm. But proteins that will act as basic regulators of development by turning other genes on and off must get back into the nucleus (where the genes reside on their chromosomes). Perhaps, they suggest, the homeodomain simply acts as a "nuclear tag," attaching to other regulating proteins that must enter the nucleus and, perhaps, facilitating their entry. I do not know whether this hypothesis has any validity, but it represents the *kind* of proposal more likely to prove useful than the superficially attractive idea that homeoboxes build segmentation directly.

In fact, we have some hints of evidence for more basic function. Homeoboxes have also been found in two of the so-called mating-type genes of yeast—genes that seem to control the stable determination of cell types in these organisms. Now yeast, obviously, are not segmented. (This argument, however, does not preclude the notion that homeoboxes regulate segmentation in insects and vertebrates. After all, the homeobox didn't arise mysteriously from nothing. It must have developed from some precursor in an ancestral unsegmented organism. This ancestral proto-homeobox may have worked in one way for ancestors and then been co-opted as a regulator of segmentation in descendants. I discussed the important evolutionary principle of such quirky shifts in function, known to biologists by the awful and senseless name *preadaptation,* in last month's column.)

We may, however, read the discovery of homeoboxes in yeast in a more positive light, not as a problem to finesse in preserving the hypothesis that homeoboxes regulate segmentation, but as overt support for the conjecture that homeoboxes perform a more basic function common to yeast and segmented organisms—some primary control in the differentiation of cell types, for example.

An intriguing hint in this positive direction comes from the apparent homology between proteins coded by the yeast mating genes and proteins in bacteria that may perform the most basic regulatory activity of all—binding to DNA. (If some genes work by regulating the turning on and off of others, then their products—proteins—must be able to bind with the DNA of other genes.) Could the homeobox code for such a central protein function as DNA binding? Such a utility would represent function at the most basic level of organic construction—a role far more general than the production of segments. By the time segments form in insects and (imperfectly) in vertebrates most of what really matters in the regulation of development has already occurred.

So where does this claim for function more general than segmentation leave Geoffroy's dream of a common ground plan for all organisms? Just when his most radical notion of homology between segmentation of insects and vertebrates seemed on the verge of revival in molecular form, along came all the naysayers and doubting Thomases of biological caution to point out that presence of a homeobox in a homeotic gene doesn't mean function *for* segmentation. These modern Cuviers, it seems, have again crushed the dream of unity after such a short and fitful flicker. Or have they?

What was Geoffroy really after? He had a vision of unity and he expressed it in the deepest and most general terms that his century knew—the generating rules of overt morphology. But Geoffroy dreamed of something deeper than external form—some underlying basis that would produce similarities of form as a necessary and superficial expression of its work. Indeed, though he invoked form *faute de mieux,* Geoffroy always sought a deeper unity that would generate form as a product. After comparing the segments of a cow and a crab, he wrote in 1807: "I have insisted upon an identity which has extended to the least important relation of all, that of form." And toward the end of his life, following his rout by Cuvier, he wrote in 1835:

ve, moreover, regenerated this principle
y of plan and composition], and ob-
ed for it universality of application, by
ving that it is not always the organs as a
le, but merely the materials composing
organ that can be reduced to unity.

n other words, Geoffroy dreamed of a
y deeper than the homology of overt
nentation, which he viewed only as the
empirical evidence he could find—
closest approach that techniques of his
e would permit to the underlying basis
mystery of development. Somewhere,
rever good biologists go, I think that
ffroy's spirit is now rejoicing that the
eobox may unite insects and verte-

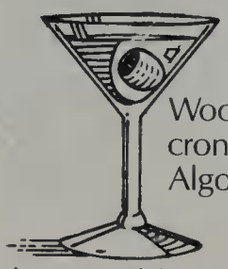
"I MUST GET OUT OF THESE WET CLOTHES AND INTO A DRY MARTINI."



So exclaimed Alexander Woollcott one rainy day to his cronies at the famous old Algonquin Round Table.

Woollcott was not alone among the literary lions in his regard for America's favorite cocktail.

Somerset Maugham and Alec Waugh were both avowed martini men.

But none, including Woollcott, was really inclined to save his martini for a rainy day.

After all, New York has been known to go weeks without rain.

Good Scents And Bad

Odors can be a mammalian aphrodisiac or a turnoff

by Adrian Forsyth

My wife smells smells that are lost on me. Just yesterday she sniffed out a tree, a tropical tree some hundred yards away, exclaiming the power of the scent. I smelled nothing until I pushed one of the deep, creamy white blossoms flush with my nose and then detected only a mild, musky smell. It is the same when we go mushrooming: she is always the first to guess that there are stinkhorns about, readily reading their rank signature on the wind. Stinkhorns are dramatic mushrooms (with names like *Phallus impudicus*) that rise from the soil in a form so true to their name it is scarcely credibl They reek rottenly, baiting the stick footed flies that will disperse their spore The difference in olfactory acumen b tween my wife and myself has nothing do with, say, the considerable differen in the size of our noses. It is simply ma and female in its division.

Women can smell some scents that m are only dimly aware of. It is probably accident that the tree I mentioned reg tered on my wife's nasal nerve endings a not on mine. It is pollinated by bats, a like most bat-pollinated flowers, its sce is a heavy, musty musk. Musk, of cours is a male-generated scent. The comme cial musk of perfumes is milked fro mammal glands. It is, or used to be, a se

ORIENT & CHINA

In TRAVCOA's Orient, you will live with Dyak villagers in Borneo, meet Torajas in the Celebes' and see ancient Burmese culture at Pagan and Mandalay. Discover Korean countryside and visit the hill tribes of Thailand.

TRAVCOA visits all of China's wonderful cities. Explore the excavations of Xian, the gorges on the Yangtze River Cruise, beautiful Guilin, the Stone Forest and Kunming. For the unusual, visit Tibet or Urumqi and Kashgar on China's Silk Route.

EUROPE

From stone-age places on Orkney Islands to Macedonian villages of Greece, TRAVCOA offers unusual itineraries of Europe.

See Holland's polders, balloon over Burgundy and the Spanish countryside, cruise the French Riviera on a private yacht, and rail over the Dolomites aboard the Simplon Orient Express.

Other European tours include Ireland, Italy, Portugal, Spain, Scandinavia, Arctic Isles, Switzerland and Eastern Europe.

EGYPT

TRAVCOA's Egypt and Holy Land tours cruise the Nile to the land of ancient pharoahs. Explore King Tut's Tomb and the noble temple of Queen Hatshepsut. See Aswan and the massive temples at Abu Simbel.

Visit Jordan's Rose City of Petra and in Israel the holy cities of Jerusalem, Nazareth and Bethlehem. Ancient Ephesus and mysterious Goreme Valley highlight your stay in Turkey.

TRAVCOA tours are limited to 25 persons, with luxury facilities and a la carte dining.

ual signal, a fact that may or may not be appreciated by perfume purchasers. Eugene Marais, the visionary biologist who wrote *The Soul of the White Ant* and *The Soul of the Ape*, commented: "Ask a young woman why she uses the heavenly perfumes the chemist of our day has learned in such exquisite perfection. Her answer will be misleading, because she does not know the subconscious reason. . . . She would be embarrassed if she learned the bases of all her perfumes were the sexual secretions of several kinds of cats, a deer, and (the most expensive of all) the rudimentary sexual material secreted by a certain kind of whale. . . ."

The human male gives off scents that are chemically related to the chemicals controlling masculinity, androgen hormones such as testosterone. One famous experiment comparing olfactory sensitivities of males and females to various chemicals showed that women are one hundred times more sensitive than men to exalotide, a compound similar to male sexual musk. This sensitivity peaks about the time of ovulation. It can be completely extinguished if a woman has her ovaries removed, and it can be restored by injections of the female sex hormone estrogen.

Sexual scent signals are widely used by other mammals. In some species a whiff of a single chemical compound is enough suddenly induce sexual interest in male female. If a female dog, one not in estru is dabbed with methyl p-hydroxybenz ate, all the male dogs in the vicinity a immediately aroused into harassing h with vigorous sexual advances.

Mammals are well known for their u of smells and tastes to signal their sexu status and for their ability at reading a testing olfactory information about oth animals. Many large grazing ungulates- camels, horses, deer—either sniff or dri the urine of females. They swill it in the mouths and draw back their lips and no trils in a characteristic grimace, a postu thought to increase sensitivity in the sam way wine tasters swill wine about in the mouths to increase the reading of its fl vor. These tastes enable a male to asse the female's reproductive conditio Males may also give off scents. Billy goa for example, will urinate and even ejac late into their goatees, a practice that co tributes to their goaty odor and that mu convey information on their sexual rea ness. White-tailed deer bucks will ejac late on the ground and wallow in the ejac late for presumably similar reasons, a other mammals, such as porcupines, u nate on their paws and present them females. Rabbit males may leap over t

females, urinating on them as a regular feature of courtship.

My farm and ranch equipment catalog offers aerosol spray cans labeled Boar Mate. Farmers can spray their sows into lordosis, the posture and attitude needed for boars to be able to mate with them. The compound in the can is androsterone, again the close relative of the sexual pheromones of humans. Androsterone was first found in human urine some thirty years ago. It is also excreted by apocrine glands in the region of the armpits and groin and seems associated with the tufts of hair growing there, as a kind of broadcasting system. There is a remarkable twist to the story of androsterone, which hogs of both sexes exude in their saliva. The same compound is given off by truffles, perhaps to attract vertebrates that eat them and disperse their spores. That is undoubtedly why hogs are such excellent truffle finders and perhaps why people are willing to pay outrageous sums for a whiff of their dank (to my mind), fungal flavor. But before you rush off to buy a can of Boar Mate for your own sexual experiments, you might consider that some women from Britain's Royal Shakespeare Company who participated in a study of androsterone (in the choice of unsprayed and sprayed seats) had their menstrual cycles disrupted. And anyone in the vicinity of swine ought to be especially cautious.

On the other hand, the odor of truffles and androsterone may have little effect on human sexual behavior. Shakespeare has King Lear saying, "Give me an ounce of civet, good apothecary, to sweeten my imagination." And some cosmetic firms have taken to selling colognes and cosmetics containing androsterone. But quantifying the effect is difficult. A few of the tests attempting to bioassay an effect of androsterone border on the bizarre. Some purport to show that seats sprayed with androsterone are more attractive to women than to men. In another study, both males and females rated photographs of women as more attractive when observers were exposed to androsterone. One test that failed to find any sweetening had students reading an erotic piece of literature while breathing through a mask containing either androsterone or a control rose water solution. Needless to say, *no* arousal was detected. Similarly, a study published in the prestigious journal *Science* with the unusual title "Changes in the Intensity and Pleasantness of Human Vaginal Odors During the Menstrual Cycle" reported that the intensity of vaginal odor declined as ovulation approached and that the male and female subjects both found the odor less pleasant at that time. The in

Here's your chance to achieve a small moral victory.

Gabriel Cortez
Colombia
Age 4

What would you do if you saw a lost, frightened child?

You'd probably stop, pick him up, brush away his tears, and help him find his way. Without even thinking about it. And there's a reason.

You know what's right.

And right now, you can do just that. You can act on instinct...by reaching out to *one* desperately poor child, thousands of miles away.

Through Foster Parents Plan, you'll be helping a child who almost never has enough to eat. A decent place to sleep. Medical care. The chance to learn. Or hope.

It's your choice.

You can even choose the child you'd like to sponsor. A boy or girl. In a country where *you'd* like to help. You'll be helping that child within his own family. And more, helping that family to work with other families to make a better life for their children.

In return, you'll receive pictures of the child. Detailed progress reports. And letters written in the child's own words. You'll see for yourself just how much you're changing your Foster Child's life for the better. Forever. And for so little.

In fact, for just $22 a month, you'll make it possible for a child to have food, medical care, schooling—and hope. That's only 72¢ a day. Imagine. Your spare change could change a child's life.

Foster Parents Plan was founded in 1937 and this year will aid over 223,000 Foster Children and their families in more than 20 countries. We are non-profit, non-sectarian, non-political, and respect the culture and religion of the families we assist. Of course, your sponsorship is 100% tax-deductible, and a detailed annual report and financial statement are available on request.

Please don't wait.

If you saw a helpless child on the street, you wouldn't wait. You'd help that instant. Please don't wait now, either. Send in the coupon—or call toll-free 1-800-556-7918.

And achieve a small moral victory that can make a big difference to a needy child.

To start helping even faster, call toll-free:

vestigators concluded that the data "do not support the notion that such odors are particularly attractive to humans in an *in vitro* test situation." That last phrase means that sniffing vaginal swabs while sitting in an air-conditioned room is not a particularly enjoyable task.

Human vaginal odor involves at least thirty compounds derived from (1) vulvar vaginal secretions from sebaceous sweat and Bartholin's and Skene's glands, (2) mucus from the cervix, (3) compounds from endometrial and oviductal glands, (4) transudate from the vaginal walls, and (5) exfoliated cells of the vaginal mucosa. Any or all or these components may produce or provide substrates from bacterial production of volatiles. Taken out of their natural context, such strong and complex odors are no more likely to be perceived as pleasant than a whiff of Limburger or anchovy paste, fragrances that many find extremely appetizing in the right place. So it is impossible to say whether there are any data indicating a pheromonal, attractive excitatory role of such odors. The literature of human emotions certainly contains much anecdotal evidence in favor of the idea. That is why attempts by cosmetic corporations to patent and market human pheromones continue. Reportedly, the fatty acids in vaginal secretions, known as copulins, have been patented but not commercially marketed. This may not be so much because of their somewhat fishy smell as because these compounds are capable of attracting the attentions of monkeys, billy goats, and other inappropriate mammalian suitors. But whether or not they will do anything to human males is unproved.

Our continued use of perfumes suggests that there is some olfactory component to our sexual interactions. What is surprising is how different modern perfumes are from what must have been the ancestral perfumes, the oozes of glands and orifices still used by mammals. It is strange that we still sprout armpit hairs, which like the hair pencils of moths, exude a scent most efficiently through the huge evaporative surface area of hundreds of bristles. But that scent is not marketed; indeed it is now almost everywhere an anathema.

Olfactory coercion, the strong bending the will of the weak through the sense of smell, is a specialty of rats, mice, and many other social rodents. As social mammals, they may give us some insights into the forces, even if they are now irrelevant, that were responsible for the evolution of menstrual synchrony. Rodents are especially sensitive to the scent signatures in urine, and they adjust their reproductive state according to what they read. Juve

e female house mice that are exposed to urine of males will reach estrus twenty ys before unexposed females. If an ult female mouse is exposed to the urine a male, within twenty minutes her erus weight begins to shoot up and her productive hormones are triggered into tion. In prairie voles this effect is so pro-unced that the weight of the female erus doubles in two days. On the other nd, if more than one female is present, e effect is reduced. When male urine is esent, female urine will inhibit estrus by ven days; if there is no male around, the hibition will last as long as four weeks. ne effect also operates on males. Urine om females accelerates male maturation hile that from other males inhibits it. nder natural ecological conditions, this eans a mother is able to suppress the re-oduction of her daughters until she dies. nd daughters or groups of females in-bit each other reproductively.

Biologists have shown that the urine of male Norway rats contains two different rborne cues that tend to cause menstrual nchrony within the social group. One ne shortens the cycle and enhances the obability of coming into estrus; the her suppresses estrus and lengthens the cle. Dominant and subdominant females may differ in the proportion of the two chemical cues they produce. Subdominants may signal their submissiveness as the payment for freedom from attack by producing the accelerating pheromone, while dominant females may produce the suppressing compound. And male urine ought to attempt to chemically countermand these signals. Male urine should be designed to bring as many females into estrus as fast as possible.

We know that male urine can influence female reproductive physiology to the female's detriment via the famous Bruce effect, named for Hilde Bruce. She discovered that if pregnant mice are exposed to the urine of a strange male, the embryos are either not implanted or are spontaneously aborted. This is another form of male infanticide whereby a male destroys the offspring fathered by another male and attempts to bring the female back into estrus, ready as a receptacle for his own genes. At first, this seems to be totally maladaptive from the female's point of view. Yet it may be a way for her to minimize her loss of investment. If the new male owner of the territory will destroy her offspring (as males do in takeovers of monkey and lion troops), then she can cut her losses by aborting immediately. Nevertheless, she still suffers as a result of the infanticidal male strategy.

Sympathizers of female rodents will be gladdened by the way the olfactory acumen of female brown lemmings influences male behavior. Females can smell success. Male brown lemmings often fight for access to females, and apparently the outcome of their battles influences their attractiveness. When females are given a choice between winners and losers (both still capable of mating), they choose winners, and they do so by use of their noses. They can distinguish between winners and losers within five minutes, an hour, or a day after the fight. Aggressiveness is important for lemmings, which periodically undergo intense crowding as a result of exploding populations. And since it is a heritable characteristic of many rodents, there is probably some value for females in choosing winners over losers.

Rodent smells are not merely urine. Beavers, for example, produce pheromones containing more than fifty different molecules. Variations in the concentrations of this many components make it possible for every individual to have a distinctive olfactory signature. This enables various rodents to recognize individuals and even to avoid incestuously mating

THE
CARIBAZON CRUISE

For the price of the Caribbean, Epirotiki also gives you the Amazon.

It's the most successful new cruise in Caribbean history. With a waiting list for each sailing this past winter.

Don't be left out in the cold next winter. Our incredible Caribazon combines the height of luxury in the Caribbean with high adventure on the Amazon.

You'll call at the choicest tropical islands. Then cruise a thousand miles up the fabled Amazon with its breathtaking fauna and flora, history and legend. And we'll have expert lecturers aboard to help you capture every engrossing moment.

A Renaissance in the Caribazon.

Our 11-day Caribazon will be performed by the world famous World Renaissance.

With all the style, marvelous cuisine and great entertainment she's famous for.

Cruises begin Dec. 22, 1985 from $2,100 to $3,000 including roundtrip airfare to the ship from Miami. The Caribbean cruise with the Amazon difference.

The trick is to book it early enough.

Are smells the guideposts that lead salmon from oceans to spawning grounds?

with individuals whose odor signifies they are too closely related.

These seem like valuable abilities. But textbooks tell us we humans have abandoned them; our sense of smell has grown superfluous while our eyes have grown keen. Yet I think it is too soon to abandon the idea that human odors might not influence human behaviors. Smell may still be bound strongly to unconscious imprinting and memory associations. We have a good example in how one man, an American specialist in fish migration, Arthur Hasler, used his experience of olfactory imprinting to gain insight into the biology of salmon homing. Three centuries ago Izaak Walton noted, in *The Compleat Angler,* that the practice of tagging salmon with a piece of string "has inclined many to think that every salmon usually returns to the same river in which it was bred." Yet how could a salmon swimming in the ocean ever find its way back to a tiny mountain stream bed?

Hasler argued correctly that salmon sniff their way home. Here is his account of how he came on the idea:

As I hiked along a mountain trail in the Wasatch Range of the Rocky Mountains, where I grew up, my reflections about the migratory behavior of salmon were soon interrupted by wonderful scents that I had not smelled since I was a boy. Climbing up towards the alpine zone on the eastern slope of Mount Timpanogos, I had approached a waterfall which was completely obstructed from view by a cliff; yet when a cool breeze bearing the fragrances of mosses and columbine swept around the rocky abutment, the details of this waterfall and its setting on the face of the mountain suddenly leaped into my mind's eye. In fact, so impressive was this odor that it suddenly evoked a flood of memories of boyhood chums and deeds long since vanished from conscious memory. The association was so strong that I immediately applied it to the problem of salmon homing. The connection caused me to formulate the hypothesis that each stream contains a particular bouquet of fragrances to which salmon become imprinted before immigrating to the ocean and which they subsequently use as a cue for identifying their natal tributary on their return from the sea.

Our sense of smell is still strong enough to haunt and beguile us. Who has not had some brief fragrance, the smell of a flower or summer rain, unleash memories and images of scenes and emotions long past which come surging back in detailed clarity. What memories may be filed under and conjured up so richly by, the scent of orange blossoms, while still other memories may await the scent of nutmeg or a thousand other redolences for their release. This link between smell and memory may now be mere atavism. But in the power of these associations we may gain an inkling of how it used to be.

CAPTAIN COOK SPENT £37,500 TO DISCOVER GLACIER BAY.

If only Captain Cook could see Glacier Bay the way you can today. From a small dent in the shore, it's grown to a 70-mile long geological spectacle of active tidewater glaciers—ranked among the world's most stunning sights. Aboard your luxurious Holland America Ocean Liner,™ a part of Alaska's highest-rated fleet, you'll be surrounded by floating ice castles, soaring eagles and perhaps even whales. We include Glacier Bay on every 7-day, round-trip Inside Passage cruise. And if you book before December 31, you'll sail for as little as $895,* saving $300 per couple. Your cruise will also visit Ketchikan, Juneau, Sitka and Vancouver, B.C., the site of Expo '86. Ask your travel agent about our Adventure Cruises, CruiseTours and exclusive Expo '86 packages, too. When it comes to exploring Alaska, only Westours lets you explore so many options.

BEFORE DEC. 31, IT ONLY COSTS YOU $895.

*Prices are per person, double occupancy, inside staterooms during economy season (Rotterdam), plus $30 port charges. Offer is $150 off per person (expires 12/31/85) and excludes 3rd and 4th persons per cabin, one-way cruises and children's fares. Ships' Registry: Netherlands Antilles.

Write to: Westours, Brochure Distribution Center, P.O. Box 9240, Seattle, WA 98109.

Very Volcanic Venus

The Venusian surface bears an uncanny resemblance to some hot spots on the earth's sea floor

by Stephen P. Maran

"I may venture to say that no eye which is not considerably better than mine, or assisted by much better instruments, will ever get a sight of them." So wrote astronomer William Herschel in the late eighteenth century, denying claims that mountaintops had been glimpsed poking through the permanent clouds of Venus.

Today we know that Venus indeed has lofty mountains, although none as tall (twenty-seven miles) as the one that the German observer J. H. Schroeter, Herschel's contemporary, claimed he had seen. Herschel's words, however, still ring true. The mountains of Venus surely have never been seen because their summits are located far below the uppermost cloud deck of the planet. Instead, the presence of the mountains is inferred from radar scans. Radar waves penetrate Venus's clouds and reveal the planet's features just as air traffic controllers use radar to search for aircraft through clouds in the earth's atmosphere. Large areas of Venus, including mountain plateaus, have been mapped with the huge dish-shaped radar telescopes at Arecibo, Puerto Rico, and Goldstone, California, and with small radar antennas carried by satellites that were placed in orbit around Venus by NASA and the USSR.

For years before the advent of radar telescopes, astronomers speculated about the nature of the Venusian surface. Inspired in part by the musings of a Swedish chemist who won the Nobel Prize for other work, some astronomers favored the theory that Venus was a humid, swampy world, its surface resembling that of the earth in the Carboniferous era, about 300 million years ago. Certain writers embellished this concept by supposing that the swamps were teeming with life, like those of the prehistoric earth. Unlike the Swedish Nobel laureate, however, there were astronomers who thought that oceans and continents are distributed on Venus much as they are on Earth. Critics of the latter theory were divided for the most part into two diametrically opposed schools of thought. According to the first school, oceans may be present, but if so, they cover the entire surface of Venus so that there is no land and there are no mountains (at least, none that rise above the surface of the sea). This remarkable concept of a watery planet was proposed only a few decades ago by two noted astronomers at Harvard University. Disagreeing with the Harvard men, adherents of the second school maintained that Venus was covered neither with oceans nor with swamps. Instead, they maintained that the surface of Venus is a broiling desert, with not a drop of water to be found.

Radar astronomers began a generation of studies of Venus in 1963. The first crude observations showed that some areas on the planet reflect radar more effectively than others. Tracking the echoes from these areas, the observers were able to measure the rotation of Venus for the first time. In the mid-1960s, however, the nature of the Venusian surface remained so much of a mystery that a radar astronomer at the Massachusetts Institute of Technology could only report that the radar echoes received from Venus were due to reflections of the radar waves at "the solid or liquid surface of the planet."

As more and better observations were obtained, the radar astronomers determined that the areas on Venus that are distinguished by stronger echoes, notably a region called Beta, which is characterized by two large mountains, are highlands. Some Venusian mountains appear to have depressions near their summits like the calderas of terrestrial volcanoes, and it is widely supposed that these mountains are shield volcanoes like the large volcanoes in Hawaii.

In October 1975, the Soviet probes *Venera 9* and *Venera 10* landed in the vicinity of Beta and sent back the first photographs of the Venusian surface. Because some astronomers thought that the surface might be only very dimly lit due to the thick clouds, the lander probes carried floodlights and their cameras were directed downward at the rocks around their landing points. The horizon in the photographs, where visible at all, is probably less than a mile from the probes, and no mountains can be seen in the distance, although at least one of the probes, *Venera 9*, may have touched down on the slope of a volcano. In any case, the *Venera 9* and *10* photographs showed a barren, dry, rock-strewn landscape.

Measurements by instruments carried by the *Venera* and other probes that have reached ground level on Venus showed that the temperature of the Venusian surface is 800 degrees Fahrenheit and more in accord with measurements by Earth-based radiotelescopes that recorded microwave emission from the planet's hot surface and atmosphere. Thus, the photographs and temperature data confirmed that the Venusian surface is a hot desert.

A remarkable property of the planet's surface is its enormous atmospheric pressure, which corresponds to about ninety-five times the surface pressure at sea level on the earth. Although there are no oceans

How to Become a "Black Belt" in Verbal Self-Defense

For anyone who's ever been pulverized by put-downs, rankled by reproaches, or irritated by insinuations, here's a revolutionary book that devotes itself *completely* to tactics of verbal self-defense. *The Gentle Art of Verbal Self-Defense* teaches you how to defend yourself *diplomatically* in delicate family situations and in the hard-nosed business world. And this book is so thorough and easy-to-understand that you can read it once and become the kind of person everybody admires—the person who stays unruffled during confrontations, who always says the right thing, and who enjoys good relations with everyone.

Stop Them with a Few Words

This book explains the various ways that people will try to bait you and then it tells you how to *stop* them with a few carefully chosen words. It trains you to defend yourself with a simple eloquence that will subdue your verbal opponents. And it shows you how and when to use blunt honesty, agreement, humor, flattery, and distraction.

Keep Cool During Arguments

The Gentle Art of Verbal Self-Defense also helps you avoid the self-defeating, overly emotional attitudes that many people assume during arguments. Once you've read this book, you'll *never again* lose an argument by being sullen, uncontrollably angry, peevishly defensive, or apologetic. You'll have gained enough savvy not to be thrown by hostile remarks.

Learn to Handle *All* Attacks

The Gentle Art of Verbal Self-Defense covers all the types of verbal attacks and attackers you're likely to encounter. And it explains both attacks and defenses with helpful features like these:

- The 8 Types of Verbal Attacks
  (and how to fight them.)
- The 4 Principles of Verbal Self-Defense
  (from *knowing* you are under attack to *following through* with your counter-attack.)
- The 5 Personalities & How They Communicate
  (Is your boss a "leveller?" Is your mother a "blamer?" Is your husband a "distracter?")
- Dialogues that Show Effective & Ineffective Defense Strategies
- Instructions on Voice Control & Body Language

These features will teach you how to deal with all types of people, including bullying bosses, backbiting coworkers, guilt-producing mothers, nagging wives, condescending husbands, and many others. And you'll discover how to counter *all* the varieties of verbal abuse — from subtle put-downs to out-and-out attacks.

Save Yourself Years of Mistakes

The Gentle Art of Verbal Self-Defense gives you a complete education in communication, an education that will improve the quality of your personal and professional relationships. On your own, it might take you years of trial and error, of fights and misunderstandings, to learn all the lessons of this book. So, why not wise up *now* by ordering your copy of the book today?

The Gentle Art of Verbal Self-Defense, originally $12.95, now costs only $6.95. And, should you want to return the book, you can do so and have your money refunded with no questions asked.

About the Author

Psycholinguist Suzette Haden Elgin has presented her innovative self-defense principles in a variety of formats. She has given workshops and seminars all over the U.S., including verbal self-defense sessions for doctors, lawyers, and other professionals. Dr. Elgin has also created a self-defense tape and a training manual for people who teach her self-defense techniques.

Questers for 1986

The pleasure of travel. The exhilaration of learning. Search out plants and animals, birds and flowers. Investigate art and antiquities. Explore rain forests, mountains and tundra, seashores, lakes and swamps. Questers sees to all the details. You have ample time to photograph, absorb and reflect. Naturalist guides, small tour parties, first-class accommodations.

Worldwide Nature Tours 1986 Departures

The Americas

Everglades: 11 days, 4/3, 11/6 • Okefenokee Swamp: 12 days, 4/13 • Hawaii: 15 days, 2/9, 3/2, 7/13 • Alaska: 17 days, 6/20, 7/8 & 26 • Pacific Northwest: 12 days, 6/16, 8/4 • Southern Mexico: 15 days, 2/2 & 16, 11/2, 12/21 • Panama/Costa Rica: 14 days, 2/10, 3/17, 12/22 • Venezuela: 15 days, 1/26, 3/2, 11/9 • Amazon: 17 days, 1/5, 3/2, 8/3, 11/16 • Ecuador/Galapagos: 17 days, 1/19, 2/23, 4/13, 7/20, 10/26, 12/14 • Galapagos: 17 days, 1/20, 2/3 • Peru: 17 days, 7/13, 11/2 • Brazil: 23 days, 8/10 • Patagonia/Tierra del Fuego: 22 days, 1/6, 11/3 • Trinidad/Tobago: 11 days, 3/3 & 17, 11/3 & 17.

Europe

Iceland: 16 days, 6/13, 7/4, 8/8 • Ireland: 23 days, 5/7 • Islands/Highlands of Scotland: 21 days, 5/29, 7/24 • Switzerland: 17 days, 7/18, 8/8 • Greece: 19 days, 4/7, 9/15 • Isles of Greece: 16 days, 4/26, 10/11 • Norway: 21 days, 6/8 & 15.

Asia & Africa

Turkey: 24 days, 9/4 • Japan: 23 days, 5/31 • Burma/Thailand: 23 days, 1/11, 11/1 • Himalayas: 23 days, 3/13, 10/9 • China Exploratory: 27 days, 4/14 • Tibet Exploratory: 24 days, 5/14 • East Africa: 23 days, 1/31, 7/18, 10/17, 11/14 • Zimbabwe/Botswana: 21 days, 7/14, 10/6 • Madagascar/Reunion/Mauritus: 24 days, 7/6, 10/5, 12/14.

Oceania & Australasia

Australia/New Zealand: 28 days, 2/8, 10/4 • New Zealand: 22 days, 2/7, 11/14 • Papua New Guinea: 25 days, 8/1, 10/31.

on Venus, previous speculation to the contrary, the surface of the planet lies beneath a heavy and hot ocean of air, consisting largely of a dense gas of carbon dioxide.

That there seem to be volcanoes on Venus is not surprising, since there are many active and dead volcanoes on the earth. Furthermore, the American spacecraft *Mariner 9* photographed spectacular volcanoes on Mars, and the NASA probes *Voyager 1* and *2* actually caught volcanoes erupting on Io, a moon of Jupiter. *Mariner 9,* however, never observed an eruption or the immediate aftermath of one during a year of monitoring Mars. From this and geologic analysis of photographs and data from *Mariner* and other Mars probes, it seems likely that the Martian volcanoes are dead.

Lacking photographs of the Venusian volcanoes, it is hard for investigators to say whether they are currently active or not. Some experts, like Harold Masursky, a leading planetologist at the U.S. Geological Survey in Flagstaff, Arizona, contend that the topographic contours of the Venusian mountain regions, as inferred from radar, are suggestive of relative youth, a circumstance consistent with activity. Thus it was with extraordinary interest that I and other astronomers greeted a February 1984 announcement that recent volcanic activity on Venus had been deduced.

The 1984 announcement, by Larry W. Esposito, an atmospheric investigator at the University of Colorado in Boulder, was based on observations from satellites orbiting both Venus and the earth. Data from the Earth-orbiting satellite *Nimbus 7* had shown that the abundance of sulfur dioxide gas in our own atmosphere increased dramatically after the eruptions of the Mexican volcano El Chichón in March and April of 1982. Esposito discovered a significant trend in the concentration of sulfur dioxide at the cloudtops in the Venusian atmosphere. In 1978, when the *Pioneer Venus Orbiter (PVO)* reached Venus, it found sulfur dioxide to be present in substantial amounts near the cloudtops, although the gas had not been present to any significant degree when searched for several years earlier. Over the next six years, as *PVO* continued to circle Venus, its measurements revealed that the amount of sulfur dioxide at the cloudtops was steadily decreasing. From these data, Esposito proposed that a huge volcanic eruption, dwarfing even that of Krakatoa in 1883, had occurred on Venus shortly before *PVO*'s 1978 arrival. The sulfur dioxide, released into the atmosphere by the putative explosion, supposedly rose upward to the clouds, where

dually it was chemically converted to
psol particles of sulfuric acid. Accord-
to Esposito, as the sulfur dioxide
ned to sulfuric acid, the amount of the
measured by *PVO* steadily decreased.
Support for Esposito's claim that there
contemporary volcanic activity on Ve-
s came from Fred Scarf, an investigator
space physics at TRW, Inc., a major in-
strial corporation in Redondo Beach,
lifornia. An instrument operated by
arf, also carried on the *PVO*, detected
-frequency radio emissions resembling
se generated by lightning storms on the
th. Scarf found that the Venus emis-
ns occurred predominantly above two
untainous regions that radar astrono-
rs had classified as volcanic based on
ir shapes. Because lightning bolts often
ke the plumes above erupting volca-
es on the earth, Scarf suggested that the
ves observed by his instrument may
e been generated in volcanic plumes
Venus.

Both the Esposito and Scarf claims
e been disputed by other planetary sci-
ists, who suggest that sulfur dioxide
ld be raised to the Venus cloudtops
here *PVO* can detect it) by means other
n volcanic eruptions and that the radio
issions detected do not necessarily
me from lightning over the mountains.

In the Footsteps of the Buddha

In October 1986, we will take a small group of travelers into the lush hills of Northern India and Nepal, retracing the life of the Buddha from his birth in Lumbini to his enlightenment at Bodhigaya. This unique journey will also take us to the idyllic Kathmandu Valley, the holy city of Benares, New Delhi and Dharamsala, headquarters of the Dalai Lama.

Other upcoming programs include:

A Sojourn in Arabia
November 29 – December 14, 1985
Travel by Land Rover through the seldom explored mountains and desert of the Arabian Peninsula and enjoy bustling oriental cities in the oil-rich Trucial States. Limited to eight participants.

Folkcraft of Morocco
February 21 – March 8, 1986
Take an insider's look at Morocco, its people and their varied crafts, from the teeming souqs of medieval towns to mountain and desert centers famed for their carpets, jewelry, woodwork and brass. We are there in time to see fantasias, tribal dances and other festivities marking national day. Limited to nine participants.

Belize — The Last Caribes
March 22 – April 6, 1986
Explore great Mayan cities and ceremonial sites, hike through verdant mountains replete with wildlife, visit with the last descendents of the Caribe Indians, or just soak in the sun and dive for lobster on America's largest coral reef in this secluded land of tranquility. Limited to ten participants.

Cross Cultural Adventures

According to one idea, sulfur dioxid present below the clouds could be raise by a process of convection, a massive a mospheric turnover. It would then de crease gradually at the cloudtops, throug transformation to sulfuric acid particles in the manner observed by *PVO*. Accord ing to some critics, the radio emissions as cribed to lightning storms above certai volcanoes might be produced instead b auroras high in the atmosphere of Venu or by lightning elsewhere on the planet Thus, the *PVO* observations, althoug suggestive of volcanic activity, are no conclusive. As for the direct observatio of a volcanic eruption on Venus, we hav yet to find the smoking gun, althoug *PVO* may have found the smoke.

The suggestion has also been made tha active or not, volcanism on Venus has a different style from volcanism on Earth Geologists use *style* in a technical sense In the context of volcanism, it refers not t what the well-dressed volcanologist wear in the field but rather to the manner i which volcanic activity is manifested. The earth, for example, has several volcanic styles, including the explosions of great cone-shaped stratovolcanoes such as Kra katoa and Mount Fuji, and the more gen tle, yet massive, repeated eruptions o molten lava that form huge shield volca noes, notably Mauna Loa in Hawaii. Stil another volcanic style is represented by the effusion of lava from submarine fis sures near the mid-ocean ridges. At those locations, called hydrothermal vents, the deep-sea water is heated and enriched with chemicals from the molten rock.

In 1979, Charles Wood, a geologist then at the Smithsonian Institution, pointed out that volcanic explosions had not been observed at great depths in the earth's oceans. Assuming that deep-sea explosions are deterred by the great pres sure of the overlying water, he suggested that explosive volcanism is equally un likely on the surface of Venus, where the atmospheric pressure is comparable to the water pressure at depths of a half mile or more on Earth. Since then, some evidence has been gathered suggesting that deep sea volcanic explosions may indeed occur. However, studies of Venus have concen trated on the likelihood that gentler lava flows like those of the Hawaiian shield vol canoes may predominate. Supporting this idea, radar maps of the Beta Regio region of Venus, which was proposed by Scarf as a source of lightning, are consistent with the identification of the area as a great complex of shield volcanoes.

Geologists at Brown University in Prov idence, Rhode Island, and at Goddard Space Flight Center, where I work, have

nsidered the possibility that the style of canism that occurs near hydrothermal nts and other areas of submarine volca- m on the earth also occurs on Venus. mes Garvin, a young Goddard col- gue and interpreter of Venusian rocks, cently told me he believes that the con- ions on Venus are very much like those terrestrial hydrothermal vents. The essures are similar, he said, and the sur- ge of Venus reaches temperatures of 0 degrees Fahrenheit and more, com- rable to, but even hotter than, those at e hottest vents beneath the earth's seas. rvin points to resemblances between ples on what look like solidified Venu- n lava flows, as photographed in March 82 by the Soviet lander craft *Venera 13*, d ripples on very young lavas photo- aphed from a submersible vehicle that plored the East Pacific Rise. Most strik- g to my eyes is the resemblance between at appears to be exfoliation (the peeling rock in thin layers along planes of weak- ss) in photographs made by the *Cyana*, French submersible craft, near the Mid- lantic Ridge and similar features found *Venera 14*'s landing point on Venus, o in March 1982. The observed Venu- n exfoliation may be due to changes in e temperature of the rocks, which cause em to contract or expand.

The surface of Venus, although not cov- ed by oceans as was once suggested, ay nevertheless resemble recently dis- vered regions of the Atlantic and Pa- ic ocean floors. Yet the Venusian sur- ce is far drier and hotter than any rrestrial desert. The explorations of both e earth's deep-sea floor and the surface Venus are still in their infancy. In many cations, our sea floor is dominated by the oducts of present and past volcanism. nus too is a very volcanic world, but nether the volcanism there is currently tive remains to be proved. Two future obes, the United States' *Venus Radar apper* and the Soviet Union's *Vesta*, are pected to reach Venus in 1988 and 91, respectively. Perhaps they will find e smoking gun.

ephen P. Maran is a senior staff scien- t in the Laboratory for Astronomy and olar Physics at NASA's Goddard Space ight Center in Greenbelt, Maryland. he opinions expressed here are his own.

Klipspringers, small African antelopes that weigh about thirty pounds, are too delicate to defend themselves against such predators as baboons and hyenas. But klipspringers are strong, nimble climbers and they are constantly alert.

Peter Johnson

Monogamy on the Rocks

For the klipspringer, an African dwarf antelope, fidelity is a life and death issue

by Robin Dunbar

From somewhere high above me on the cliff, a single shrill whistle breaks the stillness of the African dawn. I stop and scan the cliff carefully through binoculars, searching for the pair of zebra-striped ears that should be twitching nervously, pointed in my direction. Below those ears, almost indistinguishable in the jumble of rock and vegetation, will be the rest of a small fawn-colored antelope called a klipspringer.

The trick is to walk slowly enough along the cliff to attract the animal's attention but to make sure you don't frighten it into disappearing over the cliff's top. If you get it right, it will stand there stock-still, sounding intermittent alarm calls, while it considers the stranger on its territory. This gives you your chance to find its shape nestled in the camouflaging background. So long as you remain still, the animal will stay there, peering down at you over its pointed, cone-shaped muzzle, head to one side, ears probing for the slightest stir of danger. I've seen klipspringers stand like that for an hour, poker-faced, waiting to see who would be the first to move.

It was the Dutch settlers landing on the rocky shores of the Cape of Good Hope three centuries ago who gave these small antelopes their name. (In Afrikaans, *klipspringer* means "cliff hopper.") They have to be one of the best-named creatures in the animal kingdom, for they leap from rock to rock with delicate hops, pausing now and again to gaze quizzically over their shoulders at you. Among the smallest of the African antelopes, klipspringers weigh no more than thirty pounds and stand barely two feet high at the shoulder. They are stockily built, with powerful, thick limbs absolutely essential to an animal that lives on steep cliffs, where a talent for climbing can mean the difference between safety and ending up as a meal for some other animal.

I first came across klipspringers in the Simen Mountains of central Ethiopia a decade and a half ago. I was up at an altitude of 11,000 feet, and the local population was so dense that everywhere I moved I heard a choir of cautionary whistles. When you encounter an animal that often, you start to wonder about it, at first idly

Klipspringers pair off early and remain faithful to each other. Monogamy enables one animal to feed while the other acts as a lookout, but females need more food than males and thus do less guarding.

Anthony Bannister; Animals Animals

admiring its skill at negotiating sheer rock faces where a missed footing would send it spinning into oblivion, later puzzling over the details of its biology.

What struck me first was the remarkable strength of its pair bond. Field guides had always described the klipspringer as a solitary species, but I soon realized that wherever I saw one, I was sure to see another of the opposite sex. When I first encountered them, silhouetted on the skyline, only one animal was ever visible. But if I sat and watched patiently for fifteen minutes or so, the other would inevitably materialize from under a bush where it had been resting, just a few yards away. When I studied this I found that the average distance separating the pair is only about four yards. Indeed, the klipspringer is probably the most strictly monogamous of all mammals. Like many monogamous species, klipspringers live on a small territory, which they defend against intruders, using their sharp little horns to drive home the message of ownership when necessary. Such disputes occur about once every three days. In the relatively rich habitats of Ethiopia and Kenya, territories are only five to ten acres in area, but klipspringers living in the deserts of southern Africa often keep much larger territories.

One of the most conspicuous features of the pair bond is the way the animals take turns standing guard. While one guards, the other eats, and roles are alternated every fifteen minutes or so until each has eaten its fill. Then they rest (and sometimes doze) on some prominent boulder or cliff ledge that gives them a good view of the surroundings. This cycle is repeated every four hours day and night.

The significance of this was impressed on me when I carried out more detailed comparative studies in Kenya nearly a decade after I had seen my first klipspringer in Ethiopia. One of the sites I worked at in Kenya was Tsavo West National Park. Here, the animals lived on a large, boulder-strewn hill that was easily accessible to the many predators, such as leopards, hyenas, and even baboons, that stalked the dry savanna. The ground cover was very dense, consisting mainly of woody shrubs and tall grass, and an animal feeding there soon disappeared from view. In a predator-rich habitat like Tsavo, animals had almost no warning of approaching enemies. The klipspringers were particularly vigilant in this habitat. The "lookout" animal would stand on a high boulder above its feeding partner, intently watching the surrounding landscape for signs of danger. The division of labor seemed to be unusually strict at Tsavo, and the number of predators was the highest of the five sites in Ethiopia and Kenya where I studied the klipspringer. (In Ethiopia's Simen Mountains, on the other hand, predators were rare, and the mile-high escarpment provided a safe refuge. Here, the male and the female often fed together.)

I first realized the significance of this behavior when I watched one particular pair at Tsavo. The female of this pair was barely grown up and had taken up residence with the male only recently, after the death of his previous mate. As usual, the male took his turn standing guard while the female fed. When she was done feeding, she climbed up to stand beside him, nuzzling his muzzle with the signal often used to express a readiness to change roles. After a moment or two, the male descended and fed, while the female settled down to ruminate and keep watch. But a few minutes later, she became distracted and wandered off to feed in another area. The male, suddenly noticing that she was gone, bounded up onto the lookout point to take over once more. This happened repeatedly, and the poor male hardly managed to get a full meal for days at a time. Evidently, the male preferred to go hungry rather than leave the pair unguarded.

This incident underlines an important feature of the klipspringer relationship. It is not something that comes naturally. The animals have to work at it, and it takes time for a well-coordinated relationship to develop.

Most klipspringer pairs are formed when an immature animal joins one of the opposite sex that has recently lost its mate. In many couples, therefore, the animals are of different ages, though few mature before the age of two. At first the animals mesh very poorly in their newly formed pairs. But with time, things begin to improve as the newcomer makes the transition from being a juvenile with no responsibilities to being an adult that must defend its own territory and raise its own offspring.

Another example of the way in which the male and female coordinate their behavior is given by the ritual of scent-marking the territorial boundary. Once every

Anthony Bannister

A klipspringer, left, marks its territory by pressing the end of a twig into an open gland under its eye and wetting the twig with a secretion. When the secretion dries, below, it hardens into a smooth, black bead. The sight and smell of these signposts let other antelopes know that they are trespassing.

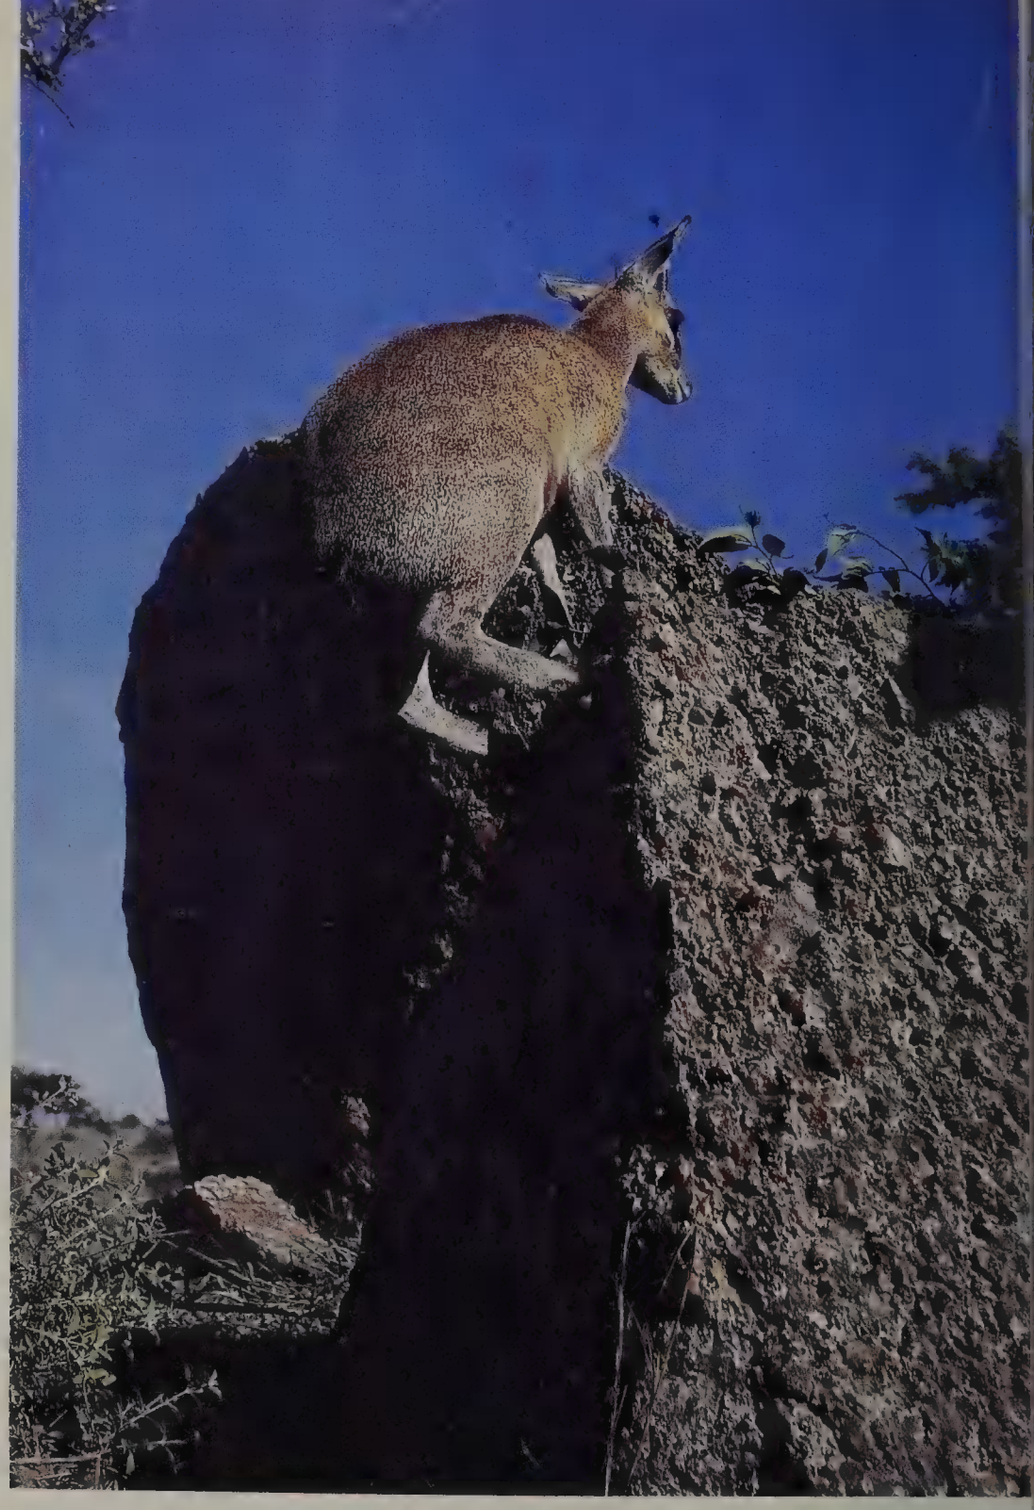
Anthony Bannister

ay or so, the pair will lay a trail of scent
arks along the edge of their territory.
sually, the female initiates the behavior
y walking suddenly toward the bound-
y. There, she marks the area by insert-
g the tips of twigs and grass stems into
n open gland just below each eye. This
aves a drop of oily, colorless liquid on the
ems that eventually dries into a glassy
lack coating. The male immediately
dds his marks on top of hers. The same
ems are used over and over again, and
ey acquire small, hard beads of secre-
on on their tips. To me, these marks have
o odor, but to klipspringers, they convey
good deal of information. They warn
eighbors and intruders alike that the ter-
tory is occupied and may even tell them
ho's there.

In most species of birds and mammals, monogamy is associated with male parental care. It tends to occur in those species in which the male's help is crucial to the survival of the young. For this reason, monogamy is common among birds but rare among mammals. It occurs in dogs and wolves, for example, because the male is able to help feed the pups by bringing meat back to the den. Some monkeys, such as the tiny South American marmoset, are also monogamous: in this case, the male helps the female by carrying the twin infants and caring for them in all ways except for suckling them. Antelopes, however, cannot carry their infants around in the way that primates do, nor do they eat the kinds of foods that can be easily brought back to a female and her young.

Another possible explanation for the evolution of monogamy in animals is that males in some species are forced into it because they cannot defend an area large enough to support several females. The klipspringer's preference for high-quality browse plants, such as flowering shrubs and herbs, may force the females to spread out, instead of forming groups as larger grazing antelope and deer do. However, the klipspringer's territory is not that big—a male could certainly defend an area large enough to cover the ranges of several females. Even if he couldn't, it still wouldn't explain why klipspringers have such an extraordinarily strong attachment to each other. The need to insure that the male be around once a year to mate with the female when she comes into estrus hardly seems to justify the immense effort required to maintain such proximity year-round. Something over and above these factors must be making it worth the male's while to invest so heavily in his mate.

Many hours spent peering through field glasses have convinced me that the answer lies in predation. So small an animal is inevitably susceptible to a wide range of enemies that includes many large eagles as well as terrestrial predators. It is particularly at risk on the flat ground at the base



of the cliffs. This is the best area for feeding, but the shrubs are so dense that the animal's field of view is greatly restricted. Ron Tilson, who studied klipspringers in the Namib Desert, found that almost all the attacks on adult animals took place while they were feeding on the flat land. My own data from Kenya tend to confirm this. In addition, a comparison of klipspringer death rates with those of dik-dik, another small antelope that lives exclusively on the flat ground in the same habitats as the klipspringer, showed that dik-dik suffer much higher predation rates.

Once I realized this, I started to see that virtually everything about klipspringers reflects predation as a selection pressure. Their whole preference for steep cliffs probably stems from a need to have both a refuge of almost unassailable safety from most terrestrial animals and an unparalleled vantage point from which to survey the landscape.

Predation even seems to account for one of the klipspringer's most extraordinary characteristics—its unique habit of walking on the tips of its hoofs. The klipspringer's hoof is turned under so the full weight of its step is taken on the conical tip. This gives the animal a characteristic, mincing sort of gait as it walks along. The value of this gait, I have learned, is that it creates ten times more friction on rough surfaces than walking on the flat of the hoof would. This enables the animal to move more quickly and with much greater sure-footedness up vertical cliffs that seem to offer no footholds. They are treacherous to walk along, and even four-footed animals are liable to slip. Klipspringers, however, get on much better than all others because their pointed hoof tips dig into the loose surface much the same way that a mountaineer's crampons dig into snow.

But what has monogamy got to do with predation? A buffalo or a zebra is big enough to defend itself and its offspring against most predators, but there is little an animal as puny as the klipspringer can do to defend itself or its mate. One thing it can do, however, is to act as its partner's eyes and ears. This allows its mate to get on with the time-consuming business of feeding without having to check constantly for predators stalking through the dense vegetation.

Does the male help the female by detecting predators more often than she does? Circumstantial evidence suggested that this was indeed so, but the hypothesis was difficult to test directly because I rarely saw predators get near the ever-alert klipspringer. What I needed was some way of knowing in advance when predators were coming.

My main study area, near Lake Elementeita in Kenya, provided me with an unexpected solution to this problem. A rough dirt road ran along the base of the mile-long cliff where the study population lived. During the course of the day, about a dozen people walked this road in ones and twos, on their way from their homesteads in the hills to a nearby market town. The klipspringer always reacted to these people as though they were predators. I was able to satisfy myself that this was so because now and again real predators, such as jackals, hyenas, and baboons, came down the track too. By defining people as randomly occurring pseudopredators, I could watch several hundred carefully controlled responses.

The road curved around the base of the cliffs at either end, so I was usually able to see people coming before the klipspringers did. I could then see which of the two animals detected the pseudopredator first and how soon it did so. I found that the male detected predators first much more often than the female did. In fact, the female sometimes saw the person only as he or she drew even with her position on the cliff.

Part of the reason for the male's acuity

Klipspringers live mainly on steep cliffs, left, from which they descend in order to feed. The animals are vegetarians and find more food on the flat ground, but that is also where predators find them.

Anthony Bannister

A couple of cliff hoppers feed on sparse shrubs. The conical tip of the animal's hoof is the key to its sure-footedness.

Anthony Bannister

was that he spent much more time than the female standing guard. Females had to spend about twice as much time feeding as males did because of the severe energetic costs of bearing young and producing the milk to nurture them. But there was more to it than just the time factor. When couples were resting side by side and facing in the same general direction, the male still picked out passers-by better than the female. In other words, the female seems to relax more, conserving her energies for reproduction.

So it seems one of the male's important contributions to the pair bond is that he is able to relieve the female of the need to be constantly on her guard. Doing so allows the male to sire more surviving offspring than if he deserted the female after mating and became polygynous. By helping to protect the female (the main caregiver), he will produce more descendants.

The male's level of vigilance is even greater when the young fawn is nursing. In Kenya, klipspringers give birth to a single fawn in March or April. Like many antelopes and deer, klipspringers leave their newborns hidden in the vegetation while the mother spends her time feeding. The fawns are not sufficiently mobile to move around with their parents until they are about three months old. In the meantime, they are easy prey for any passing predator. The fawn instinctively curls itself into a ball as soon as its mother leaves and remains motionless until the mother comes back to nurse it, often many hours later. As it is, about one in every eight fawns dies before reaching its first birthday, though not always because of predators.

I once stumbled by accident on a tiny fawn lying under a thick bush. I was moving cautiously through the scrub searching for scent marks and had stopped beside a bush to check the surroundings for signs of klipspringers. I must have been standing there for several minutes when I suddenly realized I was being watched. Not two feet from me, in the center of the bush, was a small fawn, no more than a week old. It lay absolutely still, eyeing me with an unblinking stare. At first, I thought it was dead because it did not seem to be breathing. But I hesitated to pick it up because antelopes often abandon their fawns if they have been disturbed too much. It was just as well. Looking closer, I could just make out the faint movement of the fawn's rib cage as it breathed. I edged away so as not to startle it into flight.

Once the infant is a little more mobile, it finds its own hiding place. At this stage,

A klipspringer pair check for predators in the area around a cliff. The antelopes sound an alarm whistle when they sense trouble, but they don't necessarily take off immediately. They may simply wait and watch, whistling intermittently.
Anthony Bannister

the mother does not seem to know exactly where her fawn is, only the general location where she saw it last. I suppose klipspringers do this because the fawn is less likely to be found by a predator if it keeps moving: odors that might attract a passing predator cannot build up so easily.

When the female is ready to suckle her fawn, she goes back to where she left it and begins to look around carefully, but she does not seem to be actively searching under bushes and rock overhangs. I suspect that she probably gives some kind of "milk" call to summon the fawn to her, but I never could get close enough to be sure of this. After several minutes, the fawn suddenly appears, runs across to its mother, and begins to nurse. It nurses for a surprisingly long time for such a small animal, some seven or eight minutes in all. This is probably because the female only comes to suckle it once or at most twice a day at this stage—possibly to reduce the risk of predation.

Throughout this exchange, the male stands tense and alert on a prominent rock nearby, scanning the surroundings with unusual intensity. A male klipspringer is normally quite relaxed while doing guard duty, but his whole demeanor changes during nursing. So intense is his concentration that, when I first saw it, I thought the male must have detected a predator and I kept looking around to see what it might be. I was so distracted that I never saw the fawn emerge from its hiding place and run across to its mother. It was only several minutes later that I suddenly became aware of the small brown creature butting away at the mother's side, and then, what I was witnessing finally dawned on me.

The klipspringer's is a story of single-minded dedication to solving a problem—how to avoid being caught by a predator when you are too small to do anything useful to defend yourself. It is an extraordinary example of a species' total commitment to solving that problem so that it can reproduce successfully. To be sure, every species has to avoid predators or reproduction becomes impossible. But few have done it with such unremitting devotion to duty as this little antelope. □

The Case of the Vanishing Caterpillar

A butterfly larva's fate depends on who finds it first—its ant friends or ant foes

Text and photographs by Gary N. Ross

Twenty-four years ago, I was a graduate student researching ecology in the Sierra de Tuxtla, an isolated volcanic range that rises from the Gulf coastal plain of Mexico, one hundred miles southeast of Veracruz. One remote habitat in the Sierra especially intrigued me because biologists had never noticed it. This was a small pine community found only on several of the steep ridges radiating down the southeastern slope of Volcán Santa Marta, a dormant, 5,250-foot-high volcano. There I discovered a new species of metalmark butterfly (lepidopterist Harry Clench of the Carnegie Museum honored me in 1962 by naming it Ross's metalmark, *Anatole rossi*).

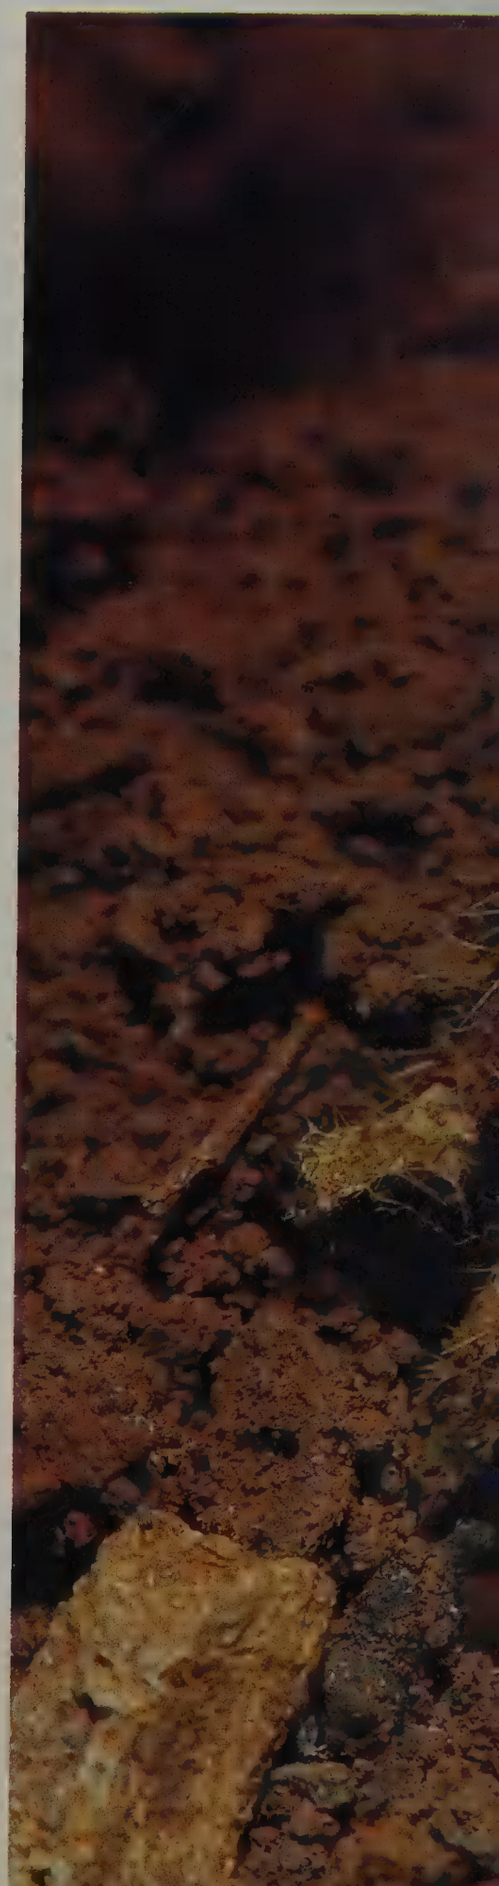
During the first month of my work in the tropics, when I began unraveling the metalmark's life history, some of the particulars came easily. I rapidly learned that the butterflies live in colonies and that females lay their eggs only on a particular species of croton, a ground-cover plant common in the region. I even discovered a few young larvae, or caterpillars. But then my luck ran out. Even though I found many severely damaged croton plants—they had apparently been eaten by mature caterpillars—I couldn't find a single large caterpillar or a chrysalis, the developmental stage in which the caterpillar metamorphoses into a butterfly. Where were the culprits?

Joe LeMonnier

I spent my days crawling about on hands and knees, often in rough terrain, searching for large caterpillars. Not finding any, I became very discouraged and resorted to hatching butterfly eggs and rearing the young larvae myself. My combination home and laboratory was a thatch-roofed, mud-floored hut, provided by my hosts, John and Royce Lind, American missionary-linguists who were studying the local Popoluca Indian culture.

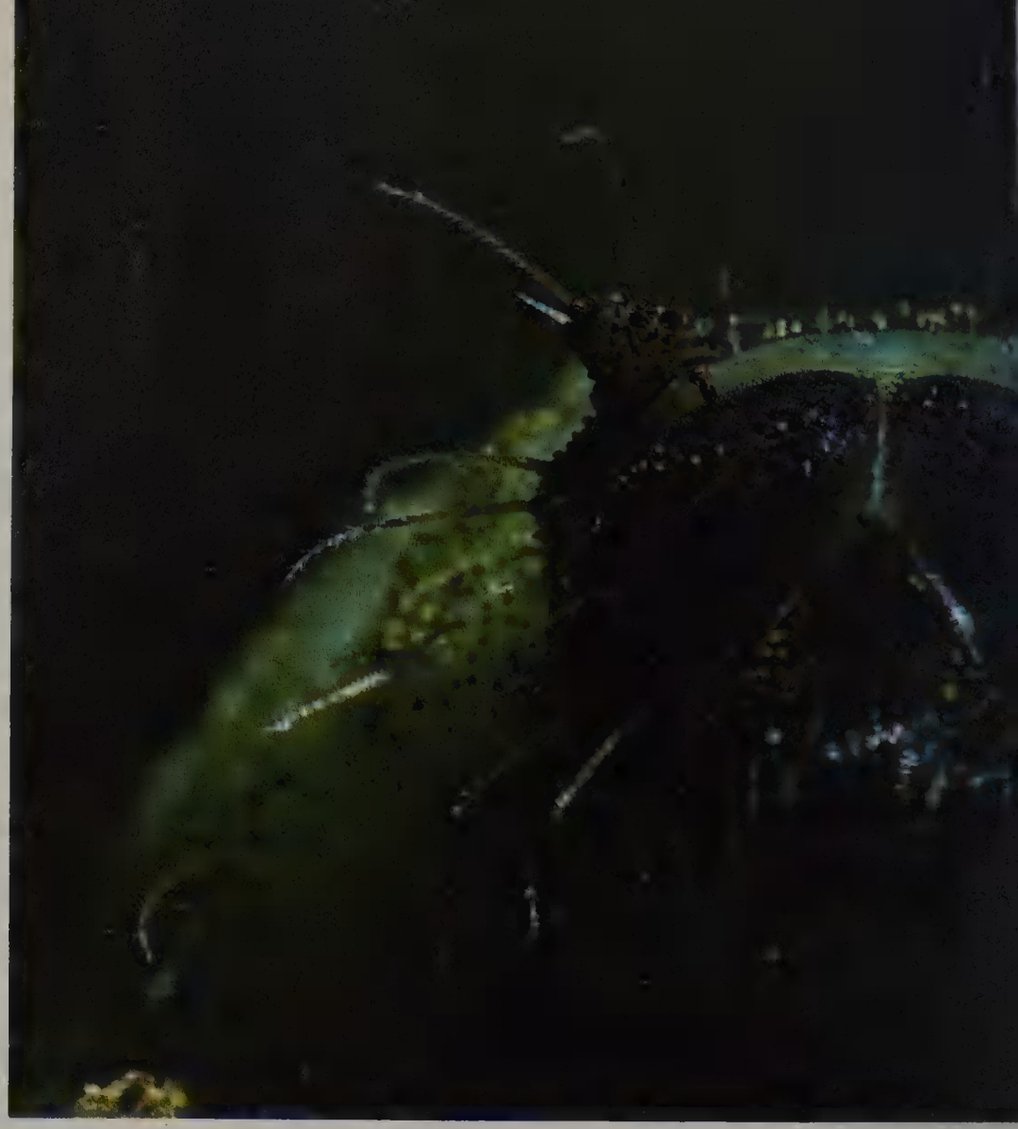
Reared in plastic sandwich-box nurseries, the young green larvae grew into large, plump caterpillars, shedding their skins six times in the process. After the second molt, each caterpillar began to secrete droplets of clear fluid from two openings on its back, near the hind end. Near its front end a pair of tentaclelike organs were periodically protruded and withdrawn. In addition, a pair of hard, bladelike structures, which constantly vibrated, projected over the caterpillar's head. At the time I hadn't a clue as to the functions of these organs, but my in-house experiments at least proved that the tiny larvae did grow into larger versions. Why couldn't I find any in the field?

One day, as I sat on a log in the midst of one of my metalmark colonies, nibbling a peanut butter and jelly sandwich (my lunch each day for several months) and pondering the mysterious absence of caterpillars, my reverie was disturbed by motion on a croton plant just three feet from where I sat. I dropped to the ground and drew closer. There, to my surprise, was a fully mature caterpillar, which I recognized from my "nursery" research.



Two Ross's metalmark caterpillars, accompanied by wood ants, emerge from the base of a croton plant.

Below: One of two honeydew-secreting glands projects from a caterpillar's hind end. An ant stroking the glands with its antennae will be rewarded with a sweet droplet.



Swarming over it were several large, reddish black ants. My protective instinct moved me to rescue the caterpillar from its predicament, but then I noticed that the ants were not attacking the caterpillar, which was feeding docilely; they were probing it, caressing it with their antennae. The caterpillar was protruding its tentacles in response, while the ants climbed aboard and drank droplets of the clear liquid that it released at its hind end.

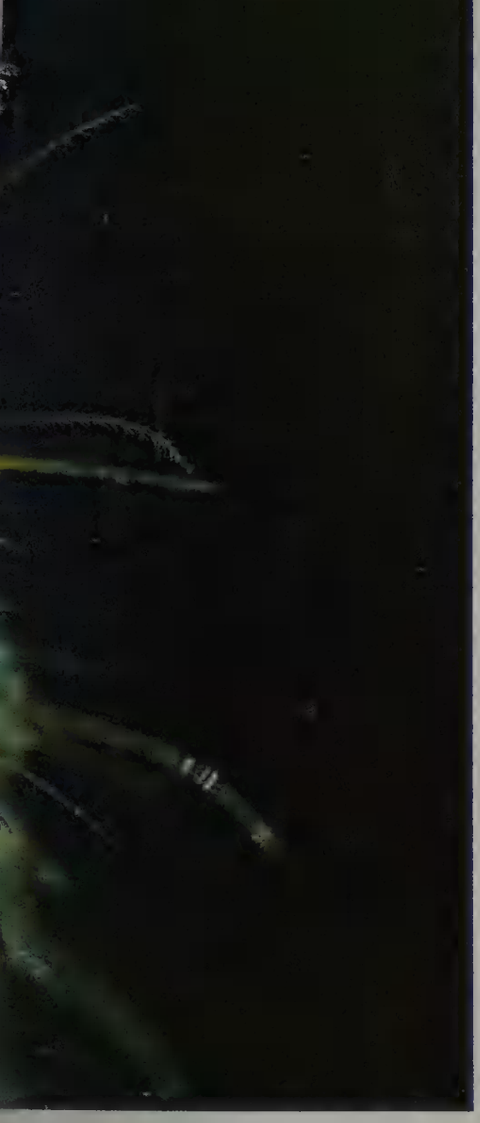
The caterpillar then began crawling down the plant, and within moments, it was in an underground chamber at the shrub's base—something I had never seen before. The ants followed, some hitching rides on the caterpillar's back. Once they were all inside the chamber, the ants closed it with dirt pellets, and all vestiges of insect infestation disappeared. My adrenalin soared! I quickly checked some partly defoliated crotons nearby. Adjacent to each plant was a subterranean niche containing from one to three caterpillars—large caterpillars—and ants; some of the chambers even contained chrysalises. Here was the solution to the mystery, and it had come about so unexpectedly. Although I've spent many years observing butterflies, caterpillars, and ants, I have never again seen these ants and caterpillars above ground during the day. They come out from their hiding places only at night. Had it not been for my chance encounter with what I like to think of as a gluttonous caterpillar sneaking in an extra meal, I probably would have given up the project of completing the metalmark butterfly's life history.

Following this revelation, I spent most of my hours—now at night, as well as during the day—on the pine ridges observing the caterpillars and their ant attendants. At night I used a flashlight covered with red cellophane, since my lantern, like any white light that the insects could interpret as dawn, disturbed the insects' activity. Even my camera's electronic flash had to be used sparingly and on intermittent nights in order to maintain nearly normal field conditions.

My nighttime excursions into the forest with camera, tripod, flashlight, and writing paraphernalia, sometimes during torrential thunderstorms, aroused the curiosity of the Popoluca villagers, whose large repertoire of folklore regarding "evils" of the night discourages nocturnal ventures. Within a short time I became the talk of the community, and speculation about my activities reached my American hosts. I learned that the most common theory about my wanderings was that I was searching for lost Spanish treasure, which the Popolucas believe to be buried in thei area. At first, this reaction elicited only a chuckle from me, but then the situatio became serious. One day I noticed tha someone had been digging in one of my colonies and had actually destroyed sev eral of my study plants and their under ground inhabitants. Since the Popolucas were unaware of the insects, they paid them no heed as they dug where I had been crouching and peering the previous night. They only wanted to see what treasure I had found.

Following this disaster, my hosts and I met with several of the village leaders. We assured them I was only a "nature lover," interested in simple things like ants and grubs on plants, and that if their digging continued, my project would be ruined and I would have to leave the area disappointed. Thereafter, I was not disturbed although I continued to elicit strange glances from many Popolucas, especially the village witch doctor, who continued to spy on me from the nearby shadows.

In the years since my discovery of Ross's metalmark, I have worked out its life history, which is probably the most complex of any known butterfly species. The butterfly is relatively small, with checkered brown, orange, white, and black markings. Like most other metal-



Protuberances over the caterpillar's head, left, shield two short sword-shaped beaters. These specialized appendages produce faint clicking sounds that attract wood ants. Below: An ant grasps a globule of honeydew in its jaws.

iarks around the world, the adults spend ıost of their time flitting rapidly two to ve feet above the ground or clinging to ıe tops and bottoms of leaves, where they ask in the sun with their wings outretched. In clear weather the butterflies re particularly visible late in the afteroon, when they dart about erratically and hase each other for short distances in the ıst rays of the setting sun.

The adult insects feed almost exclusively on the nectar from the white flowers f *Croton repens,* a wild relative of the ıore showy crotons raised indoors by ıany Americans and Europeans. The rst indication that the butterfly's life cyle is unusual is that, while the croton lants are widely distributed, the butterıes congregate in small, isolated colonies. hese colonies, which contain eight to fty butterflies, are found only on certain unny ridge crests and upper slopes and nly in the vicinity of the few human setements in the area—five small Popoluca ndian villages.

Within the butterfly colonies, the feıale insects lay their eggs on the undersurfaces of croton leaves. Hidden on the nderside of the leaves, the very young, inonspicuous green caterpillars spend their ays and nights nibbling the plants' tisues. Eight to ten days after hatching, a larva develops the specialized structures that I had noticed in my nursery. These enable it to attract its ant associates. A pair of glands near the larva's hind end produce a sugary secretion known as honeydew, which ants eat with the gusto of children devouring candy. A variety of insects—aphids, many scale insects, and to a lesser degree, certain butterfly and moth caterpillars—produce similar honeydew secretions. The tentaclelike organs near the front of the caterpillar secrete a gaseous chemical pheromone, or scent, which also attracts the ants. And the caterpillar's vibrating, bladelike structures produce faint clicking sounds, inaudible to humans but within the range of insect perception.

Not long after these specialized organs become active in a newly molted larva, the caterpillar attracts its associates, ants of the species *Camponotus abdominalis*, commonly referred to as wood ants or carpenter ants because they nest in old logs, fence posts, and even house beams. This species can be found throughout most of tropical Mexico and Central America. At night these ants scour the countryside (and villagers' kitchens) looking for, above all else, sweet things to eat. Needless to say, the *Anatole* caterpillars with their honeydew glands fill the bill.

When it first encounters a caterpillar during a nocturnal foray, the ant uses its antennae to stroke the caterpillar in the vicinity of the honeydew glands. The caterpillar responds by secreting tiny drops of moisture, which the ant imbibes. Usually within a few minutes, the ant worker is joined by several others of its kind, all of which consume the seemingly endless supply of treats. The wood ants do the caterpillar no harm, and after some thirty minutes of feasting, depart in relays to dig a small, shallow trench around the base of the croton. This excavation takes several hours but usually is complete by dawn. The resultant circular excavation is one to two inches deep. The ants then swarm about the caterpillar, constantly stroking it with their antennae. The caterpillar is induced to crawl down and soon finds itself underground. The ants quickly seal the entrance to the hole with small pellets of dirt from their previous digging. In a sense, the ant ranchers have herded their "cow" into its pen and closed the gate so that the milking becomes a private affair.

At dusk, between 7:00 and 7:10, the pellets of dirt are removed from the roof of the pen and the ants emerge, temporarily leaving their captive behind. They run back and forth over the leaves of the plant in a manner that suggests a search for potential enemies. To test if this was the

Below: In a subterranean chamber, a caterpillar attaches itself to a croton stem, sheds its skin, and becomes a chrysalis, or pupa. Although it produces no honeydew, the chrysalis will be tended by the ants for nine days of the eleven-day pupa stage.

case, on several occasions I placed small predatory arthropods, such as bugs and spiders, on the plants. The ants immediately seized these victims with their powerful mandibles, sprayed them from their abdomens with formic acid—an acrid liquid that smells something like vinegar—and carried them down the plant, depositing the virtually lifeless forms on the ground a few inches away. (Incidentally, the Popolucan name for these ants means "the sour-smelling ones." The villagers' language is rich with descriptive names for most common plants and animals; however, it doesn't contain a name for the elusive metalmark caterpillar.)

After about ten minutes of running over the plant, the ants return to the subterranean enclosure and vigorously stroke the caterpillar with their antennae, apparently coaxing it to move. The caterpillar now ascends the stem, shepherded by its carpenter ants, and eventually settles on a tender leaf near the top of the plant to begin feeding.

The feeding continues intermittently throughout the night, with the ants constantly in attendance, crawling over the caterpillar, pausing occasionally to imbibe droplets of honeydew, and running up and down the croton plant in search of marauders. The caterpillar, meanwhile, frequently emits its pheromone and vibrates its bladelike beaters, causing the ants to become more active and attentive. Between 4:30 and 4:45, just before dawn, the ants herd their charge downward and into the underground chamber. The roof is replaced, and even before the first streaks of light cross the tropical sky, both cow and herders are secure within their corral until the next twilight.

The daily cycle is rarely altered or interrupted during the summer and fall months. Even torrential rains do not have any observable deterrent effect. The underground pens are always located on sloping terrain of heavy red clay that provides excellent drainage, so the pens are rarely flooded. Besides, the insects are on the croton plants during the night, when most of the rains occur.

The caterpillars require nearly two months to complete their development. Then, like all butterfly and moth larvae, they enter a resting and transformational stage called the pupa. Unlike moth larvae, butterfly caterpillars do not encase themselves in cocoons. Instead, they attach their abdomens to stationary objects and shed their skins to reveal a new form, the chrysalis. Then, one of the greatest marvels of the insect world occurs: the lowly crawler is transformed into a winged gem of the skies.

The metamorphosis of Ross's metalmark takes eleven days. The process begins with the *Anatole* chrysalis in its chamber, attached to the subterranean portion of the croton stem or to its root. Although the organism does not produce honeydew in this stage, it does possess glandular openings corresponding in position to the pheromone-producing organs

ansformed, the pupa becomes butterfly, left. A newly emerged oss's metalmark butterfly, low, dries its wings.

the caterpillar, and I conclude that a nilar chemical is released into the air. any rate, the ants remain in the pen for ne days—until two days before the butfly's emergence. Then, as the adult rm nears perfection, its pheromone nds atrophy. The ants depart, leaving e pen open. The butterfly later emerges m the old pupal skin, climbs out of the rkness it has inhabited during the dayht hours for nearly two months, and ens the bright, sunny world of the pine ges. After an hour or so of drying and ercising its newly formed wings, the tterfly departs for a free, aerial exisnce, which it enjoys for as long as a nth, apparently oblivious to its past ant ociates.

Many questions arose in the course of observations. Do the ants remain with eir charge throughout its development do they sometimes return to their own st site? What would happen if the caterlars were isolated from their ants? Is the ociation between ants and caterpillars benefit to both species?

I experimented. First, I carefully ened a pen, and taking out the ants one one, I dabbed each on its back with a op of quick-drying paint. I repeated this ocedure with four nearby pens, using a ferent color for each. Three days later I observed that all of the painted ants had either been replaced by unpainted ones or else had moved to different chambers. There evidently was a changing of the guard as the ants circulated to and from their central nest and over their territory. Eventually I learned that the ants' nest may be up to fifty feet away, its inhabitants exploiting a variety of resources—saps, flower nectars, and other sweets. The caterpillars seem to be just one source of food they encounter. The ants' response—secreting the unwieldy prize in a hole instead of attempting to carry it back to the nest—may not have been specifically evolved to cope with the *Anatole* caterpillar. Similar behavior has been observed in several species of ants. The herding behavior may be a more specialized feature of the ants that evolved in association with these caterpillars.

In another experiment I removed the attending ants from several crotons and placed net cages around the plants to keep them out. When thus isolated from their caretakers, the caterpillars did not return to their subterranean cells after feeding but, instead, remained on the leaves and fed intermittently throughout the day and night. Evidently the daily journeys up and down the plants were forced on the caterpillars by the ants.

Then I removed several caterpillars and placed them on croton plants that were outside the butterfly-caterpillar colonies. Left unattended, the caterpillars were invariably attacked by workers of *Ectatoma tuberculatum*, large reddish ants festooned with numerous hairs and spines. This species is a member of a widespread group of ants, the Ponerinae, known for their fierce stinging ability and voracious predatory habits. The Popoluca's name for this species translates as "the robbers," appropriate for sinister-looking creatures that are frequently seen carrying assorted insect prey to their tree-hole nests.

I was personally well acquainted with *Ectatoma*. Just a few days prior to my relocation experiments, I had been stung on the thumb as I leaned against an oak tree. My finger was numb for nearly twenty-four hours and swollen for another day. I could imagine the damage such a sting would inflict on a caterpillar. I have since learned that, when stung, a larva undergoes extensive tissue destruction within a few minutes.

The relationship between the carpenter ants and the metalmark caterpillars thus appeared to be one in which the larvae furnished the ants with tasty sweets and in return received protection from a vicious armed predator, another ant species. To confirm this, I carefully investigated the pine ridge crests and upper slopes, exclusive habitats of the metalmark butterfly. The *Ectatoma* ants infested these open areas and spent the daylight hours solitarily stalking potential prey. At night, however, they remained secluded in their nests. The *Anatole* caterpillars and their wood ant guardians were prime targets, but they were hidden beneath the ground during the day when the predators were on patrol. At night, with the plundering halted as the *Ectatoma* ants stayed in their own nests, the caterpillars could feed in complete safety, exposed on their plants. Therefore, the relationship between the carpenter ants and metalmark caterpillars is mutually beneficial. Biologists call such a symbiotic relationship, in which both parties benefit, *mutualism*.

There is one other chapter to this story. During the cooler months of winter and

early spring, the ant–caterpillar activities are somewhat altered. Between November and April, nighttime temperatures may drop to 50°. Adult butterflies are no longer on the wing, having died as the cool, damp weather set in. The ants deepen the pens into five- to six-inch vertical tunnels, probably to increase insulation from the cold air. The butterfly's larval stage is greatly lengthened as the caterpillars and their attending ants become sluggish. Frequently a caterpillar will crawl up a plant during the early night hours, take a few bites, and then be herded immediately back into the pen. At times, particularly during very cool spells, the caterpillars do not emerge at all for many consecutive nights, presumably able to subsist on stored nutrients because of a reduced metabolism.

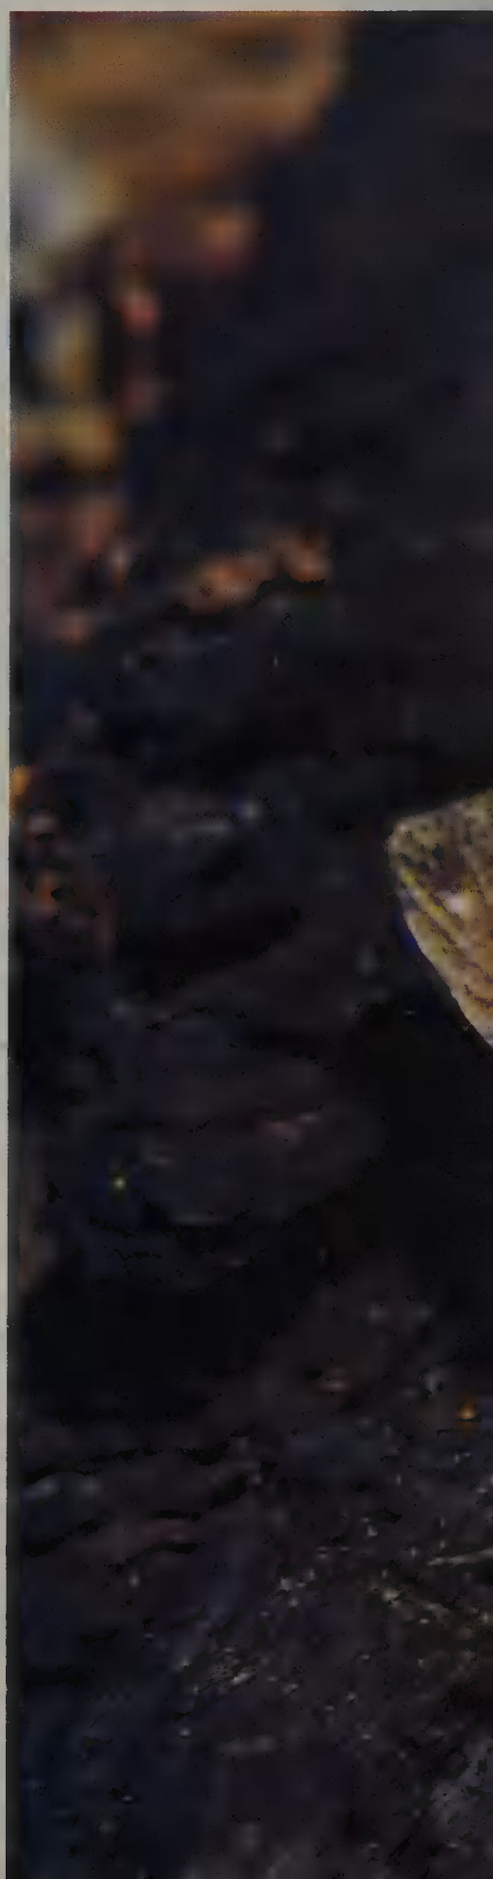
As spring, with its warmer temperatures, begins in the Sierra de Tuxtla, so does the dry season. Much of the undergrowth in the various ecological communities rapidly withers and dries. At this time, humans become an important factor in the perpetuation of the metalmark's life cycle. The Popoluca men toss lighted matches alongside the numerous trails on the pine ridges adjacent to their villages. The pine needles and dried undergrowth make excellent tinder, and the flames spread rapidly along and down the ridges. Because the ground is only sparsely covered, there is no widespread inferno, only low ground fires that creep in irregular patterns. The goal of this annual activity is to clear clutter from the ground in order to encourage the growth of fresh grasses that will serve as fodder for mules, burros, and horses. This allows the work animals to be pastured only short distances from the Popoluca villages.

By mid- or late April, selected sections of the pine ridges—and practically all butterfly-caterpillar colonies—have been burned over. However, because the wood ants previously deepened the pens during the cool months, the fires do not harm the secluded insects. They emerge the night after the firing and find a new world, one devoid of food plants and littered with burned debris. The absence of food for these winter-season caterpillars now triggers the onset of their long-delayed pupal period. No more than twelve days after fire passes through a colony, all the caterpillars transform into chrysalises. In two more weeks—by late April or early May—a fresh generation of butterflies is flying about.

Soon mating occurs and the females begin to lay their eggs. They select only the small shoots of croton plants that have recently sprouted from the bare, scorched patches of ground near their original larval food plants. The newly emerged crotons look much healthier than others growing in unburned localities. They are shorter, brighter green, and have relatively smooth leaves. The butterflies instinctively avoid placing their eggs on larger, more spindly plants with hairy leaves. While rearing caterpillars in my field laboratory, I observed that the young larvae could not penetrate the velvety surface of these larger plants; they soon became emaciated and died, presumably from starvation.

The distinctive growth form of the crotons in the metalmark colonies may be a response to the increased sunlight that pours into the burned-over areas. In unburned, grassy areas, even new-grown crotons produce hairier leaves. This difference, so important to the young caterpillars, remains in effect throughout the year. Thus, both the spring burning carried out by the villagers and the selectivity of the egg-laying butterflies insure colony stability and are critical to the survival of the species.

With the successful reproduction of the "spring crop" of butterflies, the cycle closes. Ross's metalmark seems to reproduce exclusively in an environment that is hostile to most other defenseless insects. It lives and breeds in a tiny habitat—pine ridges close to Popoluca Indian villages—that is burned regularly and systematically by the indigenous population and is the hunting territory of a potentially devastating ant predator. The butterfly thrives, where others cannot, because of its pact with a specific wood ant—a pact that, if somehow broken, would almost surely spell the butterfly's immediate extinction. □



The cycle is renewed as two metalmarks mate. The female will lay the eggs on the underside of a croton leaf. If the resultant caterpillars are not found and hidden by wood ants, they are frequently destroyed by stinging ants and other predatory insects.

Honda has a way of bringing out the best in everyone. It's called the Accord.

Whenever we introduce a new Accord, everyone else returns to the drawing board. To try their best. Now we've done it again.

This is the new Honda Accord LX 4-Door Sedan. There's nothing else like it.

The hood is lower for aerodynamic efficiency. Also, you can see better over it. The reason we can make the hood so low is that the car has a unique suspension. A double wishbone on all four wheels. It's the first time this suspension system has been used on a front-wheel-drive car. Race cars, however, have used it for years.

The new suspension does more tha give the car a beautiful shape. It gives it a lovely ride, too. The handling is outstandi We promise you'll be impressed.

You'll also be very comfortable. There is more headroom even though the roofli is lower. The car is also wider.

You'll also see through a lot more gla because the windows are larger. They al fit flush to the doors and body so there's less wind noise. The body itself is rigid and solid. The car is stable.

© 1985 American Honda Motor Co., Inc.

ns haven't de yet.

Conveniences have been well sidered. This luxurious car comes with conditioning. A new electronic stereo tem with a cassette player. There are ver windows and door locks. A power o antenna. Dual power remote mirrors.

You might call the engine more of a verhouse. Its size has been increased wo liters. And its mounts have been redesigned to absorb vibrations. It's smooth.

Variable-assist power steering takes the rough work out of parking. Cruise control makes long trips even more relaxing. And the trunk is substantially larger so you can carry more luggage.

While these extras might be available as optional equipment on other cars, they come standard on this car. We invite your comparison.

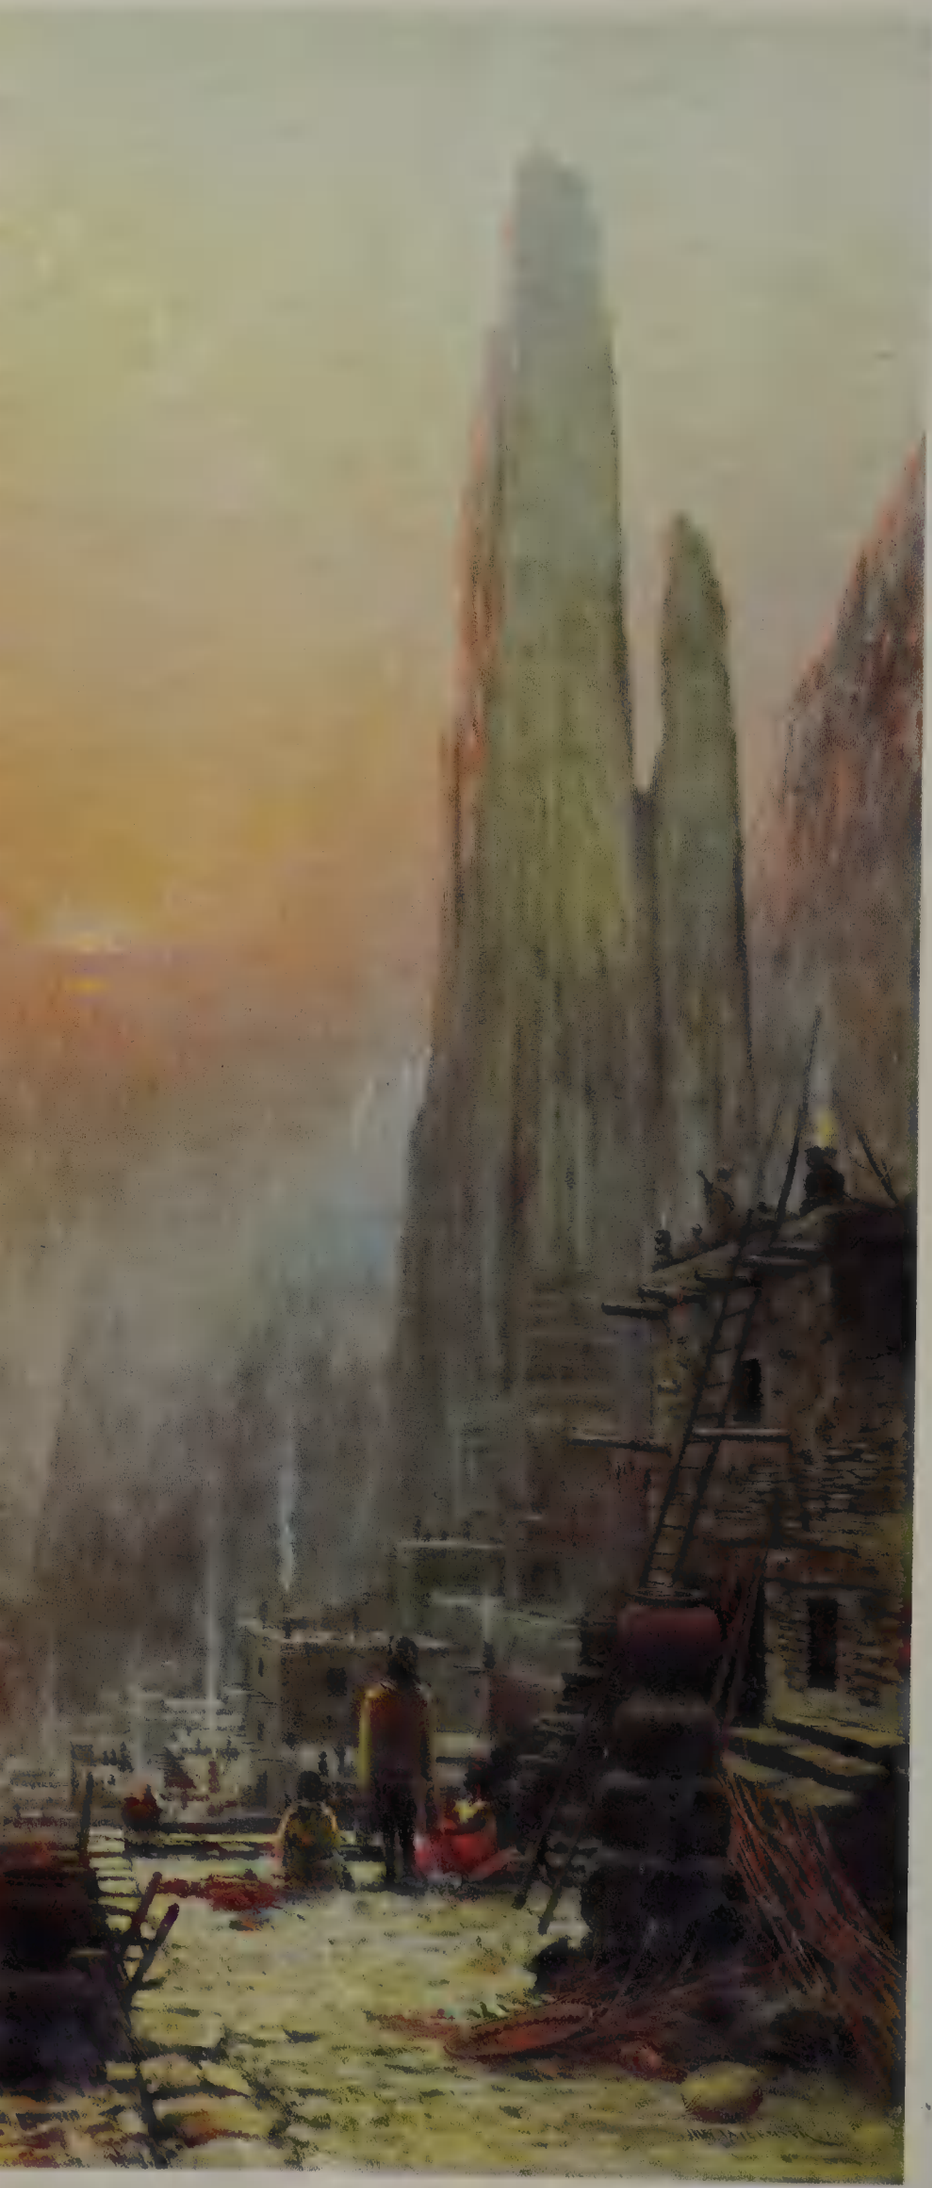
The New Accord

Visions of a Big Sky

by Daedara Cunningham

Wind River, Wyoming (1870)
Albert Bierstadt drew field sketches while traveling with Gen. Frederick Lander's 1859 expedition to survey the cross-country wagon route later known as the Oregon Trail. From these sketches, he created many of his paintings, rearranging scenery and introducing additional elements for pictorial effect.



The vast area of land loosely termed the West stretches from the Mississippi River west to the Pacific Coast, across the Great Plains and past the Rocky Mountains to the coastline of Washington, Oregon, and California. Still, the seemingly endless prairies and high, soaring mountains bow to a yet greater expanse—the big sky.

From the time of the first westward expeditions, painters have been portraying these awe-inspiring vistas. In the mid-nineteenth century, explorer-artists used a flat horizon line that broke across the painting below the center. This device, more commonly used by marine painters, allowed such artists as William Tylee Ranney, George Inness, and William Jacob Hays to emphasize the vastness of space and the clarity of the sky in the Great Plains. Attempting to re-create the emotional impact that such spaciousness had on him, Inness also used shadows and grayish colors to evoke the mystical quality of the western landscape.

In the 1870s and 1880s, monumental landscapes, such as those by Albert Bierstadt, Thomas Moran, and Jules Tavernier, stressed human isolation in a natural setting of immense scale. Dramatic skies, mountains of exaggerated height, and diminutive human figures were the characteristic features of these works. Bierstadt felt he needed a huge canvas—often as large as six feet by ten—to interpret the true proportions of the western wilderness. Moran, who first traveled west with the Hayden scientific expedition in 1871 to explore the Yellowstone region, produced spectacular watercolors that played an important role in persuading Congress to set aside the area as a national park. Tavernier's paintings, with their luminous col-

Indian Village of Acoma *(1879)*
In 1873 Harper's Weekly *commissioned Jules Tavernier to tell the story of the West by making a pictorial record of those regions "where the railroads have not yet penetrated, where . . . even the squatter, the pioneer of civilization, has not yet erected his rude log-cabin."*

Children of the Mountain *(1886)*
Thomas Moran's watercolors of the Yellowstone region prompted the Hayden survey expediton of 1871 to name a 12,000-foot peak in the Grand Tetons in his honor.

Desert Southwest *(1944)*
In 1917, Louis Hill, owner of the Great Northern Railroad, commissioned Maynard Dixon to execute paintings of the Blackfoot Indians and Glacier National Park. Later, Cubist realism, as in Desert Southwest, *became the trademark of Dixon's landscapes.*

Red Hills, Grey Sky *(1935)*
A 1929 visit to New Mexico inspired the first of numerous semiabstract paintings by Wisconsin-born Georgia O'Keeffe.

ors, huge landmasses, and images of cave-dwelling Indians, reflect the late nineteenth century's preoccupation with the exotic nature of the West.

In the early twentieth century, illustrators-turned-artists, typified by William Herbert Dunton—best known for his illustrations of Zane Grey's books—recorded the rigors of the great outdoors in depictions of cowboys wrestling with animals and struggling against the elements. This tradition of recording—and romanticizing—human exploits in the West dates at least from the time of Ranney, who was greatly influenced by popular accounts of the feats of Daniel Boone and Davy Crockett.

Modernism and abstraction have also touched the art of the West, particularly in the last fifty years. The work of Maynard Dixon reflects this direction in his use of vivid color and simplified geometric

Browning, Montana, Bicentennial Indian Encampment *(1976)*
Wolfgang Pogzeba's fascination with the Indian powwow encampment led him to travel across Wyoming, Montana, and western Canada in 1976 to photograph and paint this vanishing tradition of the American West.

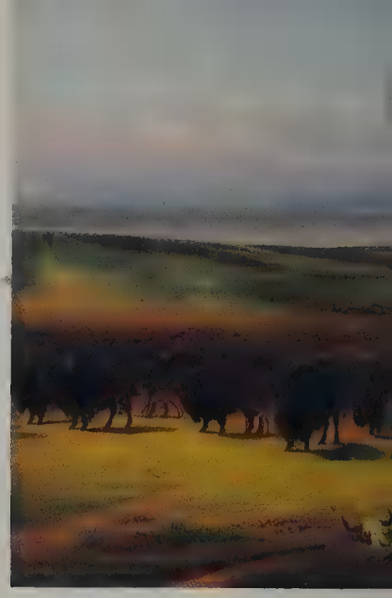
The First Iron Horse *(1901)*
Frank Sauerwein captures a moment of transition in the settlement of the West, as a group of Indians encounter the railroad. He is best known for his sketches and paintings of the Indians of Colorado and New Mexico.

form. Known for his portrayal of Indians (he lived among various tribes) and for his landscapes, Dixon was an illustrator for popular eastern magazines until 1912, when he returned to his native California determined to capture the realistic West he knew rather than the mythic West demanded by New York editors. Georgia O'Keeffe's personal vision of the West emerges in the recurring images of the empty sky and red hills of New Mexico, where, she says, "one seems to have more sky than earth in one's world." The sky is the overpowering feature of her paintings—a constant juxtaposed against hills, bones, and other elements of the landscape. The recent work of Chuck Forsman draws on two elements of modernism—realism and abstraction—to convey the expanse of the western landscape. Like Maynard Dixon before him, Forsman rebels against the romanticization of the West. A former ranch worker and park ranger, Forsman's declared artistic purpose is to depict the precariousness of the current ecological situation in the West.

While exploding urbanization and agricultural technology have brought many changes to the West, much remains unchanged: wanderers may still roam the plains and mountains undisturbed; the vastness continues to inspire awe. Above the sprawling land, as far as the eye can see, the big sky remains.

Elizabeth Cunningham is the curator and director of exhibitions for the Anschutz Collection, Denver, Colorado.

Masterpieces of the American West, a visual history of the frontier, will be at the American Museum of Natural History from November 29, 1985, through February 16, 1986. This selection of paintings from the Anschutz Collection in Denver will travel to Honolulu, Chicago, Birmingham, Little Rock, and six other cities before ending its tour in August 1988.



Dirt Rider *(1980)*
The title of Chuck Forsman's painting refers to the unseen motorcycle rider whose tracks have scarred this desert scene and, metaphorically, to each human who despoils the earth.

The Gathering of the Herds *(1866)*
In 1860 William Jacob Hays—who was born in New York City and spent his life there—made an 1,800-mile steamboat trip up the Missouri River, a journey that had an enduring influence on his work. Today he is chiefly remembered for his many large canvases of the animals of the Great Plains.

Although the village of Santa María now has tractors, some farmers continue to use teams of yoked cows. The art of training cows to the yoke is being lost by the younger generation of villagers.

Past and Present in the Spanish Countryside

Land consolidation is dismantling community practices that have been in place since medieval times

Text and photographs by Ruth Behar

In the foothills of the Cantabrian Mountains of northern Spain lie hundreds of tiny villages. Most came into being during the eighth to tenth centuries, when the first Christian Spanish kings "reconquered" lands that were under Moorish rule. Early colonists settled in the largely deserted areas and took possession of the land they could clear and cultivate, while woods, meadows, and wastes became community property. Today in León, a province of the southern foothills, the larger, greener villages stretch alongside the narrow rivers that descend from the mountains; upslope from the river banks are smaller, arid hamlets, austerely golden and brown. The village of Santa María del Condado, neither wholly green nor wholly arid, lies above the river banks yet is amply watered by springs and a communal dam.

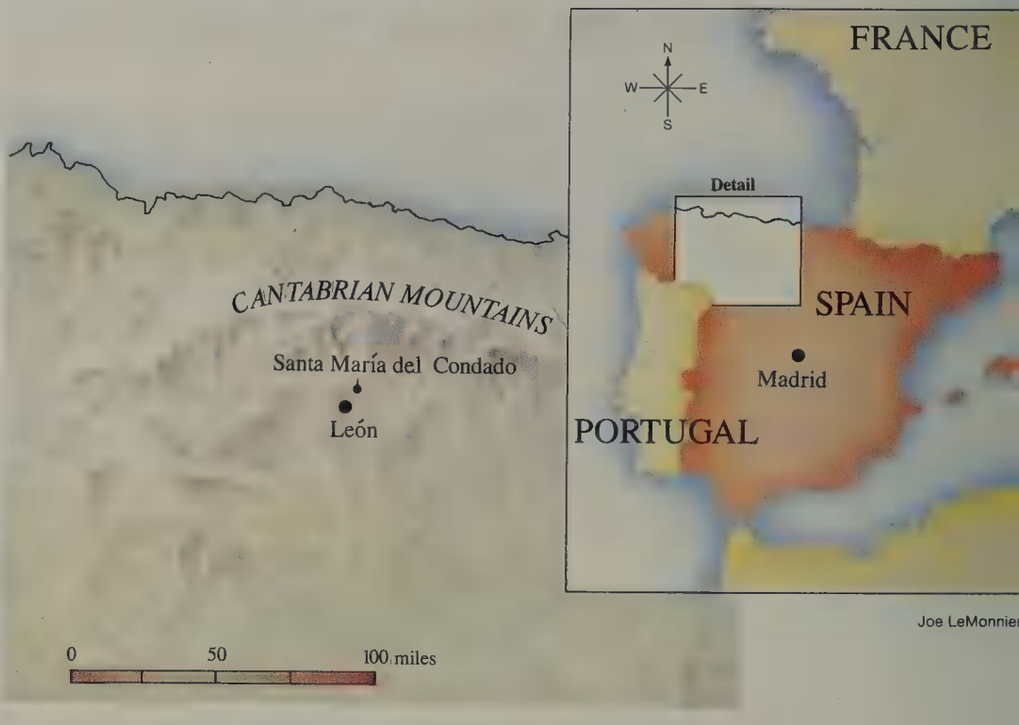
With 120 permanent residents, Santa María is distinguished by the common woods that surround the village (the community's historical name, still often used, is Santa María del Monte—Saint Mary of the Woods). The woods, which in the past secluded the village somewhat from neighboring communities, have long affected the tone of communal life. At the end of the nineteenth century, when the population more than doubled, the availability of spare woodland, which could be cleared for planting, cushioned the divisive effects of population expansion and kept village families from going hungry or sinking into the ranks of the rural proletariat. Santa María is well known in the area for having maintained a solid front during the Spanish Civil War despite political differences, unlike neighboring villages, in which some people denounced their enemies to the Civil Guards.

The ideal of unity, of *unión*, long important to villagers, was expressed in the reciprocity and cooperation of the traditional system of land tenure, which in Santa María survived until recently. During several visits to the village from 1978 to 1981, I saw farmers still following communal agricultural and pastoral practices that were once widespread throughout Spain and Europe. These included the yearly alternation of planting and fallowing the grain fields, which the entire community followed; the opening up of the harvested fields to all of the village's cattle for grazing; the imposition of community rights (what Roman law called "servitudes") on various private properties, making them subject to village use; taking turns for herding and irrigation; and finally, the allocation of common pasture and woodland to village families.

In England and elsewhere many of these practices disappeared in the eighteenth and nineteenth centuries as a result of the destruction of the commons, the enclosure movement—an early attempt to enforce land consolidation through special laws—and other measures that sought to rationalize the old agrarian system. The people of Santa María, though, like most other Leonese villagers, were barely touched by this agricultural revolution then sweeping western Europe. They continued to farm into this decade in ways that agrarian reformers had pronounced

This article is based on the epilogue to Ruth Behar's forthcoming book, *Santa María del Monte: The Presence of the Past in a Spanish Village*, to be published in the spring of 1986 by Princeton University Press.

Older people make up the majority of the villagers. Many young men and women left for León, Madrid, and Bilbao during the rural exodus of the 1960s and 1970s. Below: An older woman works in her kitchen garden.



Joe LeMonnier

irrational, barbaric, and outmoded two hundred years before.

Returning to Santa María in July of 1984, I passed through the landscape I had known so well, just thirteen miles away by highway from the city of León. I saw the familiar valleys and heather bushes, the yellow fields brimming with stalks of rye, the burnt red soil, the fallows overgrown with wildflowers and weeds, the strange wavelike patterns sewn into the hillsides by erosion, water, and time. Nearing the village, however, I began to notice the unfamiliar, to see things that tested the vision I held in my memory.

I was not surprised to find the layout of the land changed. I had corresponded with several people in the village, and their letters had charted the gradual, but imminent, progression toward land consolidation. During my previous stays in the village, the question of whether to accept the government-sponsored consolidation of the scattered parcels that made up each family's landholding had been discussed and battled over in numerous village council meetings. The program's aim is to transform the dozens of tiny fields belonging to a household into three or four larger, more regular plots, as well as to build roads to make the plots accessible by cow team or, increasingly now, by tractor. Even before my first visit, the village had requested this service, yet people acted as if the plan would never go into effect. Year after year I watched as people scrutinized the series of maps the engineers brought to the village meeting house at every stage of the process; there were so many dissatisfactions and complaints that I, too, began to believe the layout of the land would remain the same forever. But finally, in January 1984, the bulldozers finished the major roadwork, and the people were given computer printouts identifying the fields that the engineers had devised for them.

Information about the changes that were taking place had come to me in bits and pieces, but it was difficult for me to imagine exactly how the landscape had been altered. As I drew closer to Santa María, I could see, with the sort of intensity that only first impressions can call up, that the village was exposed, like a sheep just sheared of its wool. Before there had been more trees, more hedges, more gardens; now there were large fields of barley and oats reaching right up to the houses, practically touching them.

That things had changed radically, irrevocably, was not simply my own perception; it was also that of the farmers of Santa María. I remember explaining, in 1978, that I had come to Santa María to study the way of life of the village and being told, by the woman in whose house I lived that year, that theirs was a harsh life, for the work they had to do was "brutal, very brutal." A number of times I heard the phrase *la tierra es muy señorita*, "the land is a very spoiled girl"—in other words, the land will not do a thing for you, you have to work and slave "for her." On my return to Santa María, the remark I

rd most frequently, almost daily, was
t no one wants to work anymore, no one
ws *how* to work anymore.

August, as I remembered it, was the
e of greatest agricultural activity in the
r. All month long one would see people
urning from the fields with carts brim-
g with stalks of rye, the new Leonese
ed of cows—intended for milk—pull-
the load. A number of people could
y be seen in the fields or on the thresh-
grounds, and some families threshed
winnowed, with machines twenty and
ty years old, almost until midnight.
e threshing grounds would be crowded
h people, carts, cows, piles of hay and
in. A young man from the village, who
s a bar in Madrid with his brothers,
hed past me one day, saying, "This is
rse than New York City, what do you
nk, Ruth?" Theirs was hard, exhaust-
work, yet everyone was quick to point
that although they worked hard, their
ents and grandparents, not to mention
se who came before, had worked
der. In a past not too distant, the rye
s mowed with the sickle, threshed with
threshing sledge, winnowed with the
wind.

Finding the threshing grounds virtually deserted, I innocently asked people whether they had already brought in the rye harvest or if they were somehow starting late this year. I was told, by everyone, that they had not yet touched the rye, that they had contracted for combine harvesters to do the job. They would get there any day now, people kept saying, as the first week, then the second week of August passed by. People always spoke of the combines alone, not of the men with the combines, as if those imposing machines had a life of their own. It was strange to see people waiting for the harvest to be brought home for them; strange, as one man said, "that it should be August and not a soul in the fields or on the threshing grounds." When the combines arrived, just after the middle of the month, everyone breathed easier; until then there had been a great deal of anxiety in the air—what if hail had fallen or too much sun scorched the grain? So many things could have destroyed the harvest.

"In four days," Luis Puente told me, "they harvested what they used to harvest in two months." He was raised in the Basque country, where his family had moved in the 1960s. Although only twenty-two, he could remember coming back to Santa María when he was a child to help bring in his grandparents' harvest with sickle, scythe, and threshing sledge. The changes he has seen in his short lifetime, he said, amounted to a progression from "the Stone Age to modern times." In 1981 a few people had tentatively called upon the combine to harvest a field or two; before then no one had. Since then, everyone has used the combine for the rye harvest if not always for barley, oats, and wheat, which are grown in smaller quantities. "You can't work the way we used to any more," Leonardo Mirantes, a retired farmer, said to me as we stood around one Sunday talking. Sixto Mirantes, another retired farmer, added, "These days no one *wants* to work the way we used to!"

Until 1981 there were three tractors in the village; now there are seven, serving twenty-six working families. The tractor owners are the ones who, with their families, raise ten or twenty head of cattle each and work as much land as strength and time will allow. These families rent parcels from retired villagers or from those who have emigrated to the cities. Even the people who continue to work in a more traditional way, with a team of cows (oxen were given up in the 1930s), recognize that their way of life is dying and that Santa María's future as a farming village depends on increasing mechanization.

One morning, while walking through the deserted threshing grounds, I met two brothers from the village, each leading a pair of yoked cows. Both teams were made up of an older cow accustomed to the yoke and a calf wearing it for the first time. Froilán and Emiliano Mirantes led the cows around the threshing grounds for an hour or so; this, they told me, was to get the calves used to the yoke. I followed along, and we talked about how it would soon be impossible to find any beasts of burden in the village; Froilán remarked that when his neighbor, who works with a tractor, needs a team, he always borrows one from him. A certain patience is required to train a team, a certain sense of

David Fry

Before the consolidation of farmlands, everyone in Santa María had a little bit of every type of land—meadows, fields, and plots close to home for planting kitchen gardens, left. The shaded portions of the map at left show the scattered parcels of land worked by one family before consolidation. The map at right shows the holdings of the same family after the government-sponsored reforms. Below: Women sift garbanzos and sweep the threshing ground.

ıe and work and the bringing of things fruition.

For the older people, who are the major- in the village (many young people left León, Madrid, and Bilbao in search of nore comfortable, urban way of life dur- the rural exodus of the 1960s and 70s), the three, four, or five fields the gineers gave them just don't seem the me as the forty, fifty, and sixty plots that ey had accumulated through inheri- nce, destiny, and their own hard work. ıt they have accepted land consolidation th a mixture of resignation and defeat, a nse of its historical inevitability.

Once I went to observe the irrigation of me hillside lands close to the village m. I could still see the borders of the old nall plots engraved in the new landscape, if a map of the fields in the past had en placed on top of a map of the present. There I encountered Felicísimo Llamazares, a farmer in his seventies, who was beginning to irrigate with the runoff flowing down from the fields above his. He had carved out a miniature garden plot—lush with string beans on runners, onions, cabbages, and potatoes—in the middle of a large inert meadow. The upper part of the field, higher on the slope, was covered with weeds and dry grass. It could produce if it were plowed, he told me, but he wasn't going to bring in the plow. If his children wanted to, they could, but they probably wouldn't either. He said that he and his wife had already worked hard all winter cutting down trees and pulling out the old hedges to refashion their new plots.

I asked if he was pleased with the consolidation that had been carried out. He shrugged his shoulders and said that he thought that in the long run it was for the best. He had owned fifty plots, but his children no longer knew where most of them were; now, with five, they could keep track of their property more easily. Not that his children would ever work the land, he added, but who knows? And he cited a proverb: *Por los años mil, las aguas vuelvan a ir por donde solían ir* (Every thousand years the waters flow again where they once flowed). He explained that you can force water to go in a certain direction, but after a while, if left alone, it reverts to flowing the way it used to. "In other words," he said, "in twenty, thirty, one hundred years, maybe those people who left will return to where they used to be, which is the *pueblos*."

This is wishful thinking. Save for an economic disaster, those who left the villages are not going to return to cultivate the land. This realization is behind the village's approval of consolidation. The scattered plots of the past, which formed part of a web of persons, rights, and obligations, are not a meaningful inheritance to children who have moved to the cities.

With consolidation, the fields were made larger, the irrigation canals were widened, and bulldozers enlarged the old roads and plowed new ones where there had once been cultivated land. To accomplish all this, to make every field accessible by road and not just by footpath, many trees were cut down. The tree-lined lanes that led to the two communal meadows are now completely bare. When people received their new parcels, they cut down the trees and hedges within them, and many even removed the borders of foliage and knitted twigs and put up barbed-wire fences. A number of people spoke of how strange the village seems now, how foreign. New trees will be planted as time goes by, but for the moment it is the bareness that impresses.

The wastefulness of the new system as opposed to the old is often noted—how in

Rye, once harvested with sickles and scythes, below, is now harvested by machines. A combine, right, is loading the harvested grain onto a tractor wagon.

the past every ear of wheat, every stick of wood mattered, but how today thoroughness is sacrificed for speed. Those who are accustomed to working in the old style still approach the land with patience, giving it intensive attention every day without fail. But the large fields demand an extensive manner of working the land. As people point out, the very idea of plowing one of the new fields with a donkey or a pair of cows is exhausting. Nevertheless, villagers now recognize that modern farming calls for a dehumanized landscape.

A popular slogan about consolidation is "He who loses, wins" (*El que pierde, gana*). In other words, even if the fields the engineers gave you do not total up in acreage to what you had before, because all your property is now brought together, it is worth more to you—whether or not you work it yourself. For those who remain in the village and manage some, if not all, of their property, the large new parcels are more convenient. Those who are too old to farm or no longer live in the village lease their fields to the handful of tractor-owning families; now they can charge a proper rent for them because they no longer have *cachines*, little pieces everywhere, but *buenas parcelas*, good-sized parcels.

Consolidation has produced certain inequalities and irrationalities, however. As one man put it, "They say that those who lose win, but there are some who win 50,000 and some who win 500,000." The reference here is to the real estate value of the land. For example, just after the fields were consolidated, a woman who no longer lives in the village managed to sell a plot located on the edge of the settlement for 500,000 *pesetas*. Another woman, expecting to earn as much, tried to sell a plot located some distance from the settlement, but no one offered her more than 50,000 *pesetas*. The plot near the village could, and probably will, serve one day as the location of a summer house, since it can be easily linked into existing water and sewage lines. The plot at a distance, however, has value only as agricultural land, and such land is easy to come by.

When, with the help of a few villagers, the engineers rated all of the village lands, they took only the productive value of the land into account. The plots people have received with consolidation are no doubt as productive as the ones they had before, but their real estate value is another matter. In the last five years, a summer retreat has sprouted up across the highway from Santa María, on lands that were once part of the communal woods. And the young people who have moved to the city also desire a summer home, a *chalet*, in their natal village. This demand for land near the settlement has grown and will continue to grow. No wonder people use images from the lottery to talk about consolidation, speaking always of how so-and-so "wo or "lucked into" choice property.

Other inequities have come about sinc consolidation. One of the rationales b hind the old agrarian regime was that e eryone ought to have land of every type– at least a meadow, a garden plot, a field grow rye, a field to grow chickpeas, mayb even a field for wheat or oats. The plo were scattered, partly through destiny an inheritance (which, in León, has alway been equal between male and female sib lings) but also because people believe that it was better not to have all of the ha vest in one small area, where a burst hail or a sudden frost could destroy it.

The engineers who drew up the plan for consolidation fashioned nice, squar fields out of the long thin strips and jagge plots that had existed before. The notio that everyone should have a little bit land of every type made no sense to the en gineers; instead, they gave people thei new fields where they had previously ha the greatest concentration of plots. Whe I was at the threshing grounds one da

th two sisters, Inés and Amparo Rodríez, who were sifting chickpeas with a eve, Inés remarked on the small yield. ad it not been a good harvest? I asked. o, it wasn't that, she told me; it was just at, with consolidation, they had gotten any sandy fields that were good for ain, but hardly any of the thick clayey nd that is ideal for chickpeas. Before, e said, you had a bit of every kind of nd. Today there are people who don't en have a little land close to home to ant "four onions," in other words, to rm a kitchen garden.

Now that every field has access to a ad, there is no longer any need or excuse cross a neighbor's field to reach one's vn. In the past there were always probms with teams and carts causing damge to a neighbor's crops. Yet there was a nse that no one, no matter what degree self-importance he or she possessed, uld remain aloof from his or her neighrs. The layout of the land prevented it. onsolidation represents the very opposite such a conception; it frees the landholder of all servitudes, all ties to the community.

But no change in land tenure can do away at one stroke with the patterns, conceptions, and ideals of the past. Attitudes toward time, work, and the land are changing in Santa María, but these new attitudes have not replaced the old ones; instead, they now coexist, sometimes in strange juxtaposition, with peasant attitudes that have been passed on for generations. Some couples still thresh chickpeas with the threshing sledge, the women winnowing and sifting the crop with the sieve. Many families still bring the harvest home in their cow carts, and some farmers, long past retirement age, milk their five or six cows by hand every morning and evening. Men still train cows for the yoke, while miniature jewels of gardens are set in fields too large for those accustomed to close contact with the earth.

The common lands have not disappeared. Shares of the communal rye fields are given out every ten years to those families that can work them, and shares of the communal woodlands are distributed every fall so no one will lack fuel for the woodstoves that warm the houses during the cold winter months. In the summertime, most families still pasture their cows on the communal grazing lands, and participating villagers take turns caring for this communal herd, known as the *vecera*. All the 900 or so sheep belonging to village families are taken to pasture in a single herd by a shepherd from the community.

These are customs that took form in the medieval era, when, in the words of historian Teofilo Ruiz, villagers "either worked together or died separately." They continue to be practiced today in small communities such as Santa María, where people are linked by kinship and close relations with their neighbors. Yet the older attitudes and forms of social organization persist only as fragments of what was once a unified cultural system. The land consolidation has doomed them to extinction, and they will pass away with the last of the old peasant farmers. □

Only Swan Hellenic offers you...

THE EARN BOAT™

Learn your way around on a 17 day or 29 day Mediterranean vacation with 5 guest lecturers.

22 VACATION VOYAGES VISIT 180 PLACES.

Each Swan Hellenic vacation combines places you know about with others you'll want to learn about.

These sites and settings are linked to ancient legends, myths and history. You can explore the remains of Greek, Roman, Byzantine, Ottoman and Islamic civilizations.

That's why Swan Hellenic takes along guest lecturers. They offer authoritative and relevant information on the empires you'll trace.

You'll learn so much listening to these experts, you don't need to be a historian or an archeologist to thoroughly enjoy this unique vacation.

You can see the Mediterranean from whole fleets of boring cruise ships. Or, you can learn your way around with Swan Hellenic.

Ramsey's Draft, Virginia

by Robert H. Mohlenbrock

The timber in the western, mountainous part of Virginia was cut extensively near the turn of the century, and by 1910 very little of the original forest was left. Among the harvested trees were Canadian hemlocks, but they were not particularly valued for their wood. Instead, lumbermen stripped the tannin-rich bark from the trunks to sell to the tanning industry. Because the tissues that conduct water and dissolved nutrients lie in the bark, the mutilated trees soon perished. Today only a single stand of virgin hemlock forest survives in Virginia—Ramsey's Draft, in George Washington National Forest. Just a few hours' drive from Washington, D.C., and Richmond, Virginia, Ramsey's Draft is nestled below the summit of Shenandoah Mountain, where the ruins of Confederate breastworks still stand.

The name Ramsey's Draft attracted me long before I was able to visit the place itself. One of the definitions of *draft* is "gorge," and I had little trouble envisioning a deep ravine filled with stately trees and colorful mountain flowers. Looking at a geologic map, I noted that the creek that has carved the draft through centuries of cutting and washing is named Ramsey's Draft Run. *Run* has an air of excitement about it that is not usually conveyed to me when I hear the word *creek*.

Ramsey's Draft is a lush ravine nearly one thousand feet below Shenandoah Mountain to the west and Bald Ridge to the east. Through the ravine, Ramsey's Draft Run tumbles and sparkles over a bed of smooth, polished rocks. The waters that feed the run come from temporary rain-fed streams, mountainside springs, and a major tributary known as Jerry's Run, which begins as a trickle high up on Shenandoah Mountain. A primitive, dead-end road once followed Ramsey's Draft Run for nearly five miles, but in 1972, Hurricane Agnes washed away some of its stone fords. Today, this route is the main basis for a hiking trail that begins at a parking area off U.S. 250.

The trail wends its way upstream, crossing the run sixteen times. For the first two miles, the trail climbs imperceptibly from 2,252 to 2,914 feet, where Ramsey's Draft Run forks into the Right Prong and the Left Prong (the Left Prong is Jerry's Run). The forest in the ravine bottom is deeply shaded by thick stands of coniferous Canadian hemlocks and white pines, occasionally punctuated by deciduous trees—cucumber magnolia, American beech, shagbark hickory, and red maple. Mountain laurel adds a dash of color during June, while witch hazel, whose woody seed capsules explode with a sharp cracking sound in autumn, hangs gracefully over the run in several places.

Records indicate that the forest along the first two miles of the run has not been timbered since shortly after the turn of the century. But the part of the forest that has never been cut lies beyond the fork of Ramsey's Draft Run, stretching for three miles along the Right Prong. It was probably spared because of its remoteness and because its previous owners appreciated its magnificence. This virgin forest contains Canadian hemlocks nearly 150 feet tall and up to 4 feet in diameter. Occasional specimens of broad-leaved yellow and gray birches provide a contrast to the dark green needles of the hemlocks.

Canadian hemlock is common in the Maritime Provinces of Canada, as well as in much of New England, northern New York, and western Pennsylvania, but it also occurs in isolated areas as far away as southern Indiana and northern Alabama. During its early years, the Canadian hemlock is shaped like a broad-based pyramid. The long, slender branches on the lower part of the trunk are usually horizontal or even pendulous, while those higher up are ascending. In the dense shade of Ramsey's Draft, however, the lower branches die off after a few years, leaving the trunks nearly naked for up to two-thirds their length. Except for a dense covering of the evergreen spinulose woods fern on the forest

CALVERT SCHOOL

Kindergarten through 8th grade. Educate your child at home with approved home study courses, or use as enrichment. Home is the classroom, you are the teacher with the help of step-by-step instructions. Start anytime, transfer to other schools. Used by over 300,000 students. Non-profit. Write for catalog. WILD AMERICA IS OUR CAMPUS

Career programs leading to AA, B.S. and M.S. degrees

You can't fully learn about the environment by sitting in a classroom. Our expeditions are small groups of inquiring college, high school, graduate students and faculty who travel across America as a learning community. As we camp out September-May or summers—hiking, canoeing and skiing—we visit people and places to encounter deep ecological problems, society and self. Our 4-week to 4-year cross-cultural studies —Newfoundland to California—lead to naturalist, outdoor and educational livelihoods.

The Expedition Education Advantage. ❑ incorporates all previous undergraduate coursework, ❑ offers accredited career internships, independent study, life experience credit and transferable coursework, ❑ awards financial aid and career startup funding.

Send for complete information packet or inquire:

floor, there is little underbrush, so there is an extensive view through the forest, interrupted only by the large tree trunks.

The hemlock's bark, often cinnamon red, contains high concentrations of tannin, which discourages insects. The tree's flat, narrow leaves, each less than one inch long, are arranged on the branches in flat sprays, giving each leaf maximum exposure to the limited sunlight. Individual leaves persist on the hemlock for three years. They emerge from tiny buds a light yellow-green, but during their first year they become deep green and shiny.

In early May, millions of yellow pollen grains develop in small, spherical clusters at the base of the year-old leaves. While most of the pollen falls uselessly to the ground, some lands on the hemlock's erect, green, ⅛-inch-long female "flowers." Self-pollination is unlikely because a tree's female parts do not mature until a few days after pollen is released. Following pollination, tiny cones begin to develop. By the end of the year, they are three-quarters of an inch long and hang gracefully on slender stalks. Most of their seeds fall during the winter and are dispersed on transparent wings by the wind.

Although each mature hemlock produces thousands of seeds annually, only those that land in dense shade are likely to germinate. If there is an opening in the canopy left where a giant tree fell, the forest floor is more conducive to the germi tion of maples and other tree species. ter a few years, however, as the can closes overhead, the seedlings of th other trees die. As long as the hemlock Ramsey's Draft are protected from lu bering and fire, other species will not g a significant foothold.

While the spinulose woods fern do nates the forest floor, several mount wildflowers occasionally emerge throu the fronds. The delicate bloodroot and s eral kinds of white and purple violets the first to bloom in the spring, follow by jack-in-the-pulpit, cucumber root, S omon's seal, and clintonia. In summer, dainty enchanter's nightshade puts fo its tiny white flowers. As the trail cont ues ever higher along the Right Prong, casional patches of flame azalea and r azalea fill in the shrub layer of the fore

After passing through the virgin he lock forest, the trail climbs 1,400 feet less than two miles to Hardscrabble Kn The knob is very steep and covered w loosely packed gray and green fossil-be ing sandstone rocks. Hiner Spring, wh feeds Ramsey's Draft Run, seeps ou few feet below the summit. The hu shade-forming trees found at lower ele tions are absent on Hardscrabble Kn With more sunshine, red maples a black, white, and red oaks become co mon and thickets of black huckleber and an abundance of May apples, yell star grass, wild geranium, and oth wildflowers grow beneath the trees.

"This Land" highlights the biologi phenomena of the 153 U.S. national f ests. Robert H. Mohlenbrock is dist guished professor of botany at South Illinois University at Carbondale.

The #1 Fitness Exercise in the World

©1985

...can now be duplicated at home!

Fit 1 features variable resistance settings for arm and leg movements. It can challenge you no matter what your level of fitness. Duplicate the resistance of a casual glide across a flat field . . . or a tough trek through the Rockies.

The electronic console provides immediate feedback on your heart rate, speed, distance traveled and elasped time. Data that guarantees you're getting the maximum cardiovascular workout in the minimum amount of time.

You deserve the best. Now you can have it.

Cross country skiing is rated the number one cardiovascular and muscle toning exercise in the world. It's better than running. Better than exercise cycles, or rowing machines. Even better than swimming!

The unique design of ***Fit 1*** duplicates cross country skiing. It firms and tones every major muscle group in your body. And it gives you the best cardiovascular workout available.

Fit 1 can get you in the best shape of your life. All on one simple machine that folds for easy storage.

To learn more on how you can enjoy the number one fitness exercise in your home, call anytime for our free brochure.

The Unportable Field Guide

by Michael Harwood

There's not the slightest doubt in my mind that video cassettes represent the next "great leap forward" in the genre denominated field guides, particularly field guides to the birds. But even if you have $74.95 just burning a hole in your pocket during the Christmas rush, do not invest your money in this "video guide" as a gift for your favorite birder. It will disappoint the experienced bird chaser and confuse and frustrate the novice.

Within a few years the equipment for playing video cassettes will be as miniaturized and portable as battery-powered audio cassette players are today, and we'll be able to carry our video-playing gear with us as we race across a mud flat after an unfamiliar shore bird. Now, however, this video guide must be used either at home or in some handy Winnebago.

AUDUBON SOCIETY'S VIDEOGUIDE TO THE BIRDS OF NORTH AMERICA. *(cassette 1); $74.95 in VHF and Beta.*

But imagine what a television guide to the birds could do even today if it were well put together. First, it could be a superb teacher. It could do what no book can—show each species in characteristic motion and simultaneously let the viewer hear a representative variety of vocalizations. With repeated replays you could spend as much time as you wanted watching and listening to an unfamiliar species—and at close range—until you had it nailed into your memory bank.

In cases where males of the species differ in appearance from the females, the videotape could display a living, breathing pair together—feeding, courting, or whatever else shows off the differences well. It could present adults and young in various interesting stages of plumage and activi It could show characteristic behavior th would help a birder learn to identify t species—a flock of white pelicans spir ing up on a thermal, for instance, or a male northern goshawk on the wing, reening through a thicket as she charg an intruder that had approached her ne too closely. It could do a great many su things. And simply by being a sheer light to watch and listen to, it would pro elytize for the protection of birds a thereby of the world's environment.

But what do we have here? We have video show that mostly emulates a pri field guide instead of going beyond it. Th video guide was written, directed, and na rated by Michael Godfrey, son of the la Arthur Godfrey, and coproduced by Go frey and Richard Stadin, president MasterVision, Inc., which distributes Godfrey has had access to the definiti audio library at the Cornell Laboratory Ornithology, and with the help VIREO—the top-of-the-line, pioneerin photo archive at the Academy of Natur Sciences of Philadelphia—he has draw on a large collection of bird photograp by such luminaries as Eliot Porter, Alfre Eisenstaedt, Olin Sewell Pettingill, J and others. Roger Tory Peterson, king the printed field guides, provides the intr duction. The completed video guide wi run *eight* hours and will be sold in four se ments, each to be priced, presumably, $74.95 or more. This flagship segment— the first two hours of tape to be released— deals with the loons, grebes, pelican ducks, geese, diurnal raptors, and chic enlike birds of North America.

It is, unhappily, not a rich collection exciting cinematography and videotape birds in life. To be sure, motion segment are scattered throughout it, but less than

third of the individual species descriptions include moving pictures. A few sequences are tantalizingly good; the courtship dance of the western grebes springs immediately to mind. But many of the sequences are only snatches, about one to three seconds long. There are also selections of bird calls for many—but far from all—the species shown.

In short, there's not nearly enough of the sort of material that could make this video guide exciting and unique. It is at heart a collection of still photographs and range maps that are displayed on the screen while Godfrey reads an abbreviated text. Its resemblance to a print field guide is inadvertently heightened by the Peterson-style indicators that point to key field marks on the bird photographs.

The annual index for
NATURAL HISTORY, VOLUME 93
(January through December 1984)
may be obtained by writing to:
INDEX
Natural History
Central Park West at 79th Street
New York, N.Y. 10024

It doesn't even do much of a job as a dressed-up print field guide. Start with the visual aspects. The stills may often be great as photographs, but if you are going to display birds in frozen poses instead of in motion, photographs, by their nature, are far less helpful than drawings as aids to identification. The people who have chosen to illustrate field guides with photographs argue that photos are better than drawings because they show real birds, not idealized ones. But most bird photographs contain too many distractions and distortions of reality—tricks played by angle and perspective, light and shadow, film-stock and processing—to be truly representative of any subject species as a whole.

In this video guide, for example, while the narrator's voice-over is describing the "orange-red" face mask—actually the facial skin—of the red-faced cormorant, the viewer is looking at a photograph of a cormorant with a *canary yellow* mask. Flaws of that sort may be the result of a seasonal variation in the species concerned or an idiosyncracy of the individual bird or the result of the process that produced the original still photograph. Who can tell? In any case, the photographs are misleading, and a good many of them appear out of focus. These complaints could be blamed on the viewing equipment, so let me add here that I watched my first run-through of video guide at the home of a former work radio and television engineer keeps up to date on developments in tel sion equipment, and the television set used was a model well known, accord to my friend the engineer, for its faith color reproduction and sharpness. friend also pointed out that at the be ning of the tape the narrator urges view to check the color balance of their sets, the producers haven't offered color bar the start of the tape to make checking adjusting possible, so viewers wh equipment isn't properly color balan are going to be even more unhappy w the colors than I was.

The narrative is no better than mostly static illustrations. It is humdr and terse, and partly because of the s plification enforced by brevity, it inclu some questionable (or worse) infor tion—for example, that the blue-win teal "nests in prairie potholes," whic does not do in the prairieless New Engl and Atlantic coast part of its range, that the population of the trumpeter sw once dropped to as few as sixty-six indiv uals (when that swan count was made 1932, most of the trumpeter's nesting wintering areas were still unknown to ence, so the counters censused only a sm fraction of the actual population—and fact, they found sixty-nine, not sixty-s The text is not well matched to the vis effects. The viewer may be looking at aspect of a bird while Godfrey is talk about another aspect altogether, whic very distracting. The narration also peatedly highlights the paucity of mot on the visual side—for instance, menti ing, but not displaying, the shall wingbeat of the red-tailed tropicbird. A watched, I was more than once moved shout at the invisible narrator, "W *show* it, for heaven's sake!"

The old writing rule about showing stead of telling applies particularly wel a television production, and the miss opportunities here are legion. Except the bird vocalizations, which are ava able—and better—in commercial au tape collections, this video guide offers atively little more than what a bir could find in a good printed field guide certainly not 74 dollars and 95 cen worth more. Television is the next hi ground for bird identification aids right, but my advice for this Christmas spend the money on *books* about birds

Michael Harwood, who has written seve books on birds, is coauthor with his w Mary Durant, of On the Road with Jo James Audubon.

MEMBERS' NEW YORK WEEKEND

NEW YORK, NATURALLY!

MEMBER'S NEW YORK WEEKEND

(Designed exclusively for Members of the American Museum of Natural History)

Whether your first love is art or archeology, elegance or evolution, stars of the heavens or stars of Broadway, you'll find it in our Members' New York Weekend. For three exciting days and two wonderful nights, a great Museum and a great city will be all yours.

The Weekend program includes:

- Two nights in one of New York's finest hotels: The Waldorf Astoria, The Plaza, or The Parker Meridien.
- A complimentary lunch and breakfast.
- Free tickets to the Hayden Planetarium and the extraordinary Naturemax Theater.
- A free copy of the Official Museum Guide.
- A free Highlights Tour.
- Personalized Service to help customize your weekend to suit your needs and tastes.
- Special Discount Airfares.

Only $92.50 per person per night, tax included (based on two nights, double occupancy). Special discount rates also available for individuals and families.

For more information:

Call: 800 435-8776

Jungle Maintenance

by Marshall Schwartzman

For twenty years now, Ray deLucia has been cleaning Africa. Sixty-nine years old, bespectacled, and sporting a waxed handlebar mustache ("to let people know I'm the artistic type"), deLucia, chief preparator emeritus of the Museum, has been restoring the habitat groups of the Akeley Hall of African Mammals one by one.

As originally conceived by Carl Akeley, Museum explorer, taxidermist, and preparator, the hall was to be a monument to the wildlife of Africa. By the second decade of the twentieth century, the "great white hunters" of Europe and America and the spread of agriculture were already threatening Africa's big game with extinction. Akeley lamented this prospect in a 1926 letter to the Museum from Africa: "I have not appreciated the absolute necessity of carrying on the African Hall, if it is ever to be done, as I do now after this painful revelation. The old conditions, the story of which we want to tell, are now all gone, and in another decade the men who knew them will all be gone."

A few months later Akeley died of dysentery in Africa. But he left behind plans and blueprints, realized ten years after his death as the hall that bears his name.

The presentation of Akeley's twenty-eight habitat groups in specially designed cases, known as dioramas, marked a chance marriage of the work of two M seum pioneers. In 1902, while Akeley w still at the Field Museum in Chicag Frank Chapman, a colleague at the Am ican Museum, was busy designing a n means of displaying birds. As a young b Chapman had visited the Museum learn more about the local birds he h seen in his native New Jersey. But found he could learn little from the d plays in the Museum; specimens we mounted as solitary trophies on the wa or thrown together in display cases. Bir from disparate parts of the world or fro widely differing climates might be fou together in the same group, and there w little, if any, attempt to place the exhibit its natural environment.

When Chapman was hired by the M seum in 1888 as an assistant curator of nithology and mammals, the placing birds in groupings as they would be seen the wild had already become popular the Museum. These arrangements repr sented an advance over the haphazard, rio-cabinet-type of display Chapman ha seen on his childhood visit. Although was an improvement, this second gener tion of displays still lacked the realist foregrounds and backgrounds that wou set off the animals. Chapman's sugge tions gave birth to the first complete hal

Proudly Presenting...

"The Freedom Eagles"

By Michael Boyett

Size of statue approximately 12" high.

A powerful, new, original work of art portraying two American eagles soaring freely in full flight.

- **Individually cast, hand-finished and hand-rubbed to the rich luster of classic bronze.**
- **Serially numbered, hallmarked and accompanied by a Certificate of Registration.**
- **Issued in a Limited Edition of only 9500 sculptures.**

Wheeling aloft through the vast American skies, two superb American eagles touch, for an instant, in a brief moment of shared freedom. It is an extraordinary sight which has inspired the famed American sculptor, Michael Boyett, to create his dramatic new work, *"The Freedom Eagles."*

A powerful portrayal of the soaring symbols of our nation's liberty, *"The Freedom Eagles"* is now being issued for the first time ever by the New England Collectors Society, a subsidiary of Reed & Barton Silversmiths, the distinguished American firm which has been creating fine products since 1824.

"The Freedom Eagles" is issued in a permanently Limited Edition of only 9500 individually serially numbered sculptures. Each sculpture will also be hallmarked and accompanied by a Certificate of Registration.

Exceptionally detailed to a degree of intricacy that will astonish you, each *"Freedom Eagles"* sculpture is individually cast in cold-cast bronze, the special blend of finely powdered bronze and resins which captures even finer detail than traditional hot-casting. It is a masterpiece of American art in a museum quality casting that is destined to be a treasured family heirloom.

To acquire your *"Freedom Eagles"* by Michael Boyett, *no payment is required now.* But be sure to mail your reservation application right away.

The New England Collectors Society is a subsidiary of Reed & Barton silversmiths, makers of fine products since 1824.

tat group at the Museum—the Cobb's Island group. Chapman added a concave background mural to enclose the entire display space behind a glass front and set it in a wall. Within this space, Chapman set breeding terns on a shell-strewn beach, which receded into the background mural and created the illusion of three dimensions. The effect was that of a window into nature, and the object, as Chapman later said, was to present the subject "in such a manner as to render apparent the bird's place in nature and its relation to man."

The diorama method of display quickly became a favorite of curators and the public alike. The three-dimensional, naturalistic presentations offered viewers an unprecedented experience in museum-going. Nothing in the Museum approached the dioramas' aesthetic appeal and educational value, and crowds came to see the new exhibits in record numbers.

This was just the type of prominence and striking realism that Akeley envisioned for his collections, and the dioramas created for the African hall were the finest examples of their kind. Although previous Museum dioramas had achieved their aim of scientific accuracy, few reached the level of realism Akeley demanded. Often the mural painters lacked the skill to create the illusion of three dimensions on a flat canvas and the foreground and background were imperfectly integrated, leaving a sharp line where t foreground ended and the mural bega

So where some dioramas in other ha made do with a flat background mu and one, two, or even three glass sid (making them more like cases than dio mas), every display in the Akeley hall w a fully enclosed and realized natural s ting. Specially selected and trained arti re-created exact locations, seasons, a time of day. More than ten years we spent collecting specimens—from zebr and giraffes to gemsboks and okap Boulders and trees that couldn't brought back from Africa were sketch or photographed in the field and later created in the Museum. The method preparing the mountings had been devis by Akeley. Previously, skins had be stuffed with almost any material at ha (straw and cloth, for example). T Akeley method started with a clay mod of the animal sculpted onto the posed sk eton and anatomically correct to the la muscle. From this a plaster model w cast and the hide fitted, creating a mou ing unparalleled in terms of form. T Museum sometimes spent up to $50,0 on a diorama (it would cost at lea $100,000 to build the same diorama day).

For all their care and attention to deta though, the designers and builders of t Akeley hall could not protect their c ations from the effects of time, and by t early 1960s, the dioramas were showi signs of age. Dirt accumulated on t background murals, dust settled on t mountings, leaves drooped and shrivele and the brilliant colors of the anima hides faded. Something had to be don and for the first time in thirty years the oramas were opened. To do the work, t Museum turned to Ray deLucia, one the few people still alive who had work on the construction of the dioramas.

Beginning with the oldest groups—t gorilla habitat and other dioramas on t first floor—deLucia, and later Steph Quinn, an artist-preparator with the M seum, set to work. Once the 8- by 14-fo pane of glass that enclosed the exhibit w removed, the lush underbrush and mou tainsides of the Kivu volcanoes of We Africa beckoned. DeLucia entered t place that Akeley had once called "t most beautiful spot in the world." But had to tread carefully. "Once you get there, you think you're in the jungle," sa deLucia, "but you have to know whe you can step and where you can't."

Airbrush in hand, deLucia ginger made his way along a path leading dow the mountainside. Beginning with t foreground, he cleaned the foliage a

NordicTrack

Cross Country Skiing Exerciser

Builds Cardiovascular Fitness More Effectively Than Other Exercisers

"NordicTrack provides the same superior fitness building benefits as real X-C skiing."

8 time Nat'l X-C
Ski Champion
Olympic Silver Medalist
World Cup Winner

©PSI 1985

NordicTrack duplicates the smooth, rhythmic motion of cross country skiing, recognized by health authorities as the most effective fitness building exercise available.

Jarless Action is Better Than Running

Does not cause joint or back problems. More complete. Resistance on arm motion provides a superior upper body exercise.

More Complete Than Exercise Bikes

Adds important upper body exercise and provides more uniform leg muscle usage. Higher pulse rates, necessary for building fitness, seem easier because more muscles share the exercise.

More Effective and Safer Than Rowing Machines

Safer because no dangerous back strain loads imposed. Scientific tests prove NordicTrack's skiing motion is superior to rowing for building fitness.

Burns off 200 - 600 Calories per 20 Minute Workout

For effective weight control.

Exclusive Flywheel Action

Provides unmatched smoothness and continuity from stride to stride. Motion and resistances are same as real skiing.

Folds Compactly

Requires only 15" x 17" floor space.

NATURAL HISTORY DIARY & ADDRESS BOOK

Very rare natural history illustrations grace the *1986 Natural History Diary* and *Natural History Address Book*. All are exactingly reproduced from the hand-colored plates and hardbound in an elegant volume. These extraordinary plates were selected from the finest examples of 18th and 19th century natural history art in the rare book collections of the American Museum of Natural History, the British Museum, the Royal Horticultural Society, and the Victoria and Albert Museum of London. These two volumes may be ordered separately or as a set. Makes a superb gift.

☐ Yes, I would like to order the 1986 Natural History Diary and/or the Natural History Address Book. Price for the Address Book is $19.50; Price for the Diary is $18. For the set, $35. No charge for shipping and handling.

The four corners of the Akeley hall ha the largest, most exotic dioramas. The three Grevy zebras above are part of t water hole group.

mountings, careful not to damage the de cate and sometimes brittle models. A sol tion of detergent and water removed th dust and grime from cotton and wax doo plants and pendent ferns. In the center the scene, a large blackberry bush ha shriveled from years of neglect. With hot-air gun, deLucia directed a steac stream of heat at the leaves, which r sponded like newly blossoming flowers. T his right, he doused a small female goril munching on wild celery, and farth down the path, a rare mountain squirr hidden in a lichen-covered tutsan plan To his left, he aimed his airbrush at a fea some male gorilla beating his breast.

To reach beyond the jungle floo deLucia constructed a raised wooden pla form on stilts, just high enough to clear th gorillas. From there he sprayed the tre limbs that hung above the scene and ap plied the detergent mix to the sky an background murals.

After about a month, the gorilla grou was renewed, and deLucia moved on t the adjoining Libyan desert scene. Here there was no nettlesome foliage to clean o repair, just a trio of addax antelopes, scimitar-horned oryx, and an addra ga zelle foraging on a leafy green deser plant, set against a sandy landscape punc tuated by a few rocks. After a simpl

AMNH

ning, a new light box was installed to ce heat, the greatest enemy of the di-nas. Heat fades the pigments of hides, es dust into the murals and the ani-s' fur, and causes plants to wither. t of this heat came from giant incan-cent bulbs, which were the standard ns of illumination in the 1930s. Since , cooler fluorescent lights have be-e the prevailing means of lighting n displays, and as a matter of course light boxes in each of the dioramas e rebuilt to incorporate these fixtures. y combining incandescent and flu-cent types of lighting, the artists were to make the settings more dramatic. fluorescent lights brought out the , even light of the African sky, while incandescent lights, with their strong, used rays, cast shadows and created illusion of sunbeams. But once this light box was installed in the Libyan up, an entirely new problem appeared: even light of the fluorescent bulbs cast adow under each of the antelopes, but dows were only supposed to appear to side of each animal, simulating the ef-t of the setting sun. Luckily, the sand s not real but plaster, and deLucia was e to paint out these unwanted shadows. as he might, though, he could not nt away the shadow cast from the hind arters of the largest of the addax. Not to be defeated by a mere shadow, Lucia painted a new bush on the mural he shaded spot and molded a new rock place before the bush.

Such artful innovations served deLucia ll during the course of the restoration. w samples of soil cannot be obtained m Africa for every faded patch, and

Offer good only in continental U.S.A.

Relive 2,500 years of civilization in Sri Lanka.

See for yourself Anuradhapura's monuments and reservoirs constructed in the 4th Century B.C., Dambulla's famous rock temple caves and the 2,200 year old sacred Bo-Tree. Discover the incredible Sigiriya's citadel with mirrored walls and frescoes from the 5th Century A.D., Polonnaruwa's Buddhist shrines and Kandy's temple of the sacred tooth relic. Experience all this amidst the tea gardens, wildlife parks and miles of beaches with the friendly people of this beautiful island paradise.

Between Pacific Tides
Fifth Edition

Edward F. Ricketts
Jack Calvin & Joel W. Hedgpeth
Revised by David W. Phillips

Including John Steinbeck's Foreword to the 1948 edition. One of the classic works of marine biology, *Between Pacific Tides* describes the habits and habitats of the animals that live in one of the most prolific life zones in the world—the rocky shores and tide pools of the vast Pacific Coast. Now completely revised, expanded by nearly 20%, and incorporating over 200 new illustrations and a new chapter on the factors that influence the distribution of organisms along the shore, it is an unsurpassed introductory text for students and professionals and an invaluable guide for the amateur. The Index and Bibliography now contain some 2,300 entries. Illustrated with 425 photographs and drawings. $29.50

Stanford University Press

MALAYSIA and Borneo

Explore startling different Malaysia and the island of Borneo on a Journeyworld tour designed for small groups and independent travelers. Take a river safari to a tribal longhouse, hike through primeval forests to pre-historic cave paintings, savor the tranquil lifestyle of riverine villages. Exclusive services at affordable prices.

Jupiter Stands Out

by Thomas D. Nicholson

The planets become increasingly difficult to observe this month as they gather around the sun. Jupiter is the only planet easily seen; actually it is hard to miss. Look for the brightest starlike object in the sky after dusk. Jupiter shines prominently in the south after sundown, setting in the west-southwest before midnight. The planet makes an attractive scene with the moon on the 17th amid the bikini-shaped star group in Capricornus.

During November, Mercury and Saturn are both evening and morning stars but are not conspicuous as either. Venus was a good morning star earlier in the fall, but this month it rises only about one hour ahead of the sun and will thus be difficult to view. Mars, more distant to the sun's right (west), rises about four hours before sunup. Look for the planet near the brighter star Spica in Virgo in the southeast at the onset of morning twilight.

Many of the planets are not well placed for our viewing this month, but we can still enjoy the beautiful autumn constellations. The great Square of Pegasus passes high in the south during the early evening hours with Andromeda, Perseus, Cassiopeia, Cepheus, and Pisces nearby. Because of lengthening autumn nights, the bright summer stars linger in the west following sunset; in the east are the brilliant stars of Orion, Taurus, Auriga, and Canis Major, which will soon dominate our skies during the long cold nights of winter.

The following events are given in local time unless otherwise noted.

November 1: The gibbous moon, in Taurus, trundles above the horizon two hours past sundown. When it rises higher, a triangle of bright stars surrounds it: Auriga's Capella above; Aldebaran in Tau (look for the V-shaped Hyades) to its rig and below; and Pollux and Castor, t twin stars of Gemini, rising below.

November 3: The moon rises abo 9:00 P.M., near Pollux and Castor, closi with them during the night. Before daw it passes below Pollux, making the twin threesome.

November 5: Last-quarter moon (3: P.M., EST) is in Cancer but slides into L before rising in the east after 11:00 P.M

November 6–7: The waning cresce moon drifts through Leo, passing bright star Regulus while below the ho zon on the 6th. The view is best in t morning with the moon to Regulus's rig on the 6th and to its left on the 7th.

November 8: Mercury reaches greatest distance east of the sun. In the a tumn, however, the path of the planets the sky is at a very low angle with the ho zon at sunset, so Mercury will be near impossible to observe.

November 9: The moon helps in fin ing Mars in the dawn sky just below the l nar crescent in Virgo. The bright st Spica is even lower.

November 11: The crescent moon hid Venus from Earth (an occultation) abo 6:00 A.M., EST, for sky watchers south the equator. But viewers in the Northe Hemisphere can't even see the player much less the drama, since Venus and th moon will fade quickly in the twilight aft they rise.

November 12: Spring tides and a sola eclipse accompany the new moon (at 9:2 A.M., EST). Perigee (when the moon nearest Earth) comes about an hour ea lier and is bound to prime high tides t

Permanent pleasures.

Choose one of these five sets and save up to $305.50

You simply agree to buy 4 books within the next two years.

eethoven: The Nine ymphonies & The Five iano Concertos

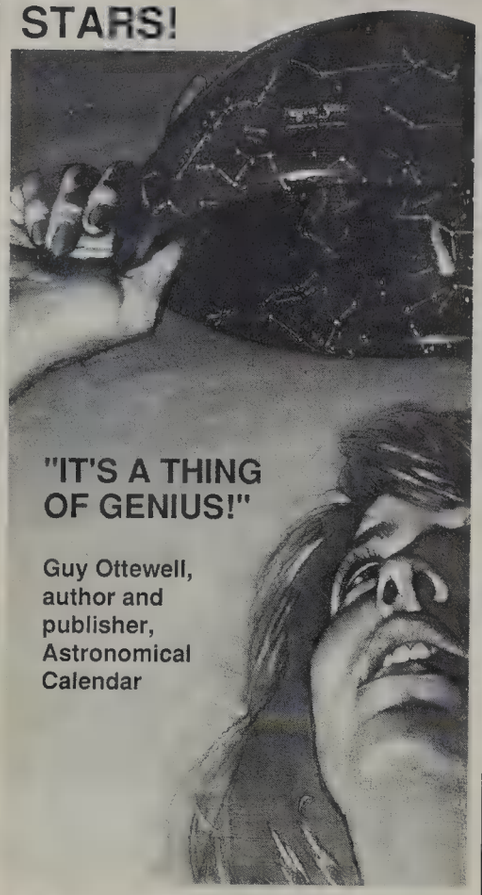
THERE'S SOMETHING NEW UNDER THE STARS!



"IT'S A THING OF GENIUS!"

Guy Ottewell, author and publisher, Astronomical Calendar

NightStar®

At last! The *only* dome-shaped star map affording you an *undistorted* view of the heavens from *anywhere* on Planet Earth! **NightStar's** patented sliding flexible surface adjusts instantly for *any* location, time or date! The secret lies in a slippery film of oil, sealed permanently within this high quality *four-color* star-hemisphere. Durable and compact (just 8" across, yet equal in area to a 20"x10" flat star map!) **NightStar** lets you follow the stars as *never before*. After viewing a prototype of **NightStar**, the late R. Buckminster Fuller wrote:

"I am deeply impressed with the excellence of your pocket planetarium. I have very many astro-aides, enough to have made me feel at once the significance of your beautifully designed product."

Included with **NightStar** are a 60 page 'step-by-step' handbook (with notes for the younger stargazer), Time Dial and Latitude Finder *plus* both Halley's Comet and Planet Finder overlays! All handsomely packaged.

NightStar makes a wonderful gift! At your request, we will ship to the person you specify and forward your receipt to you.

Special introductory price $44.00 plus shipping & handling - U.S & Canada $3.50; foreign $7 surface, $14 air. All U.S. orders sent *promptly* UPS if *street* address given.

California residents add 6% sales tax.

Please send check or money order to:

NightStar Company

Santa Cruz, CA 95062, U.S.A.

night and tomorrow. The eclipse is austral, however, covering Antarctica and the waters around it, with totality limited to a small path in the South Pacific.

November 13: The moon occults Mercury in the southern Eastern Hemisphere, but the two are above the horizon only during daylight and twilight.

November 14: The young crescent moon appears in the evening sky, in the southwest at dusk.

November 16–17: If the weather cooperates, conditions will be ideal for the Leonid meteor shower. The moon sets early both nights. The shower usually produces up to fifteen meteors per hour from about 1:00 A.M. to dawn. They are often bright, bursting objects.

November 17: The beacon in the south all month is Jupiter, drifting into the west and setting before midnight. The crescent moon joins it tonight in Capricornus.

November 18: Mercury loops int retrograde path on the way out of the ning sky.

November 19: First-quarter moon (A.M., EST) is just over the border betv Capricornus and Aquarius.

November 21: The vernal equinox, known as the First Point of Aries, is above the moon, and the Square of P sus is above both.

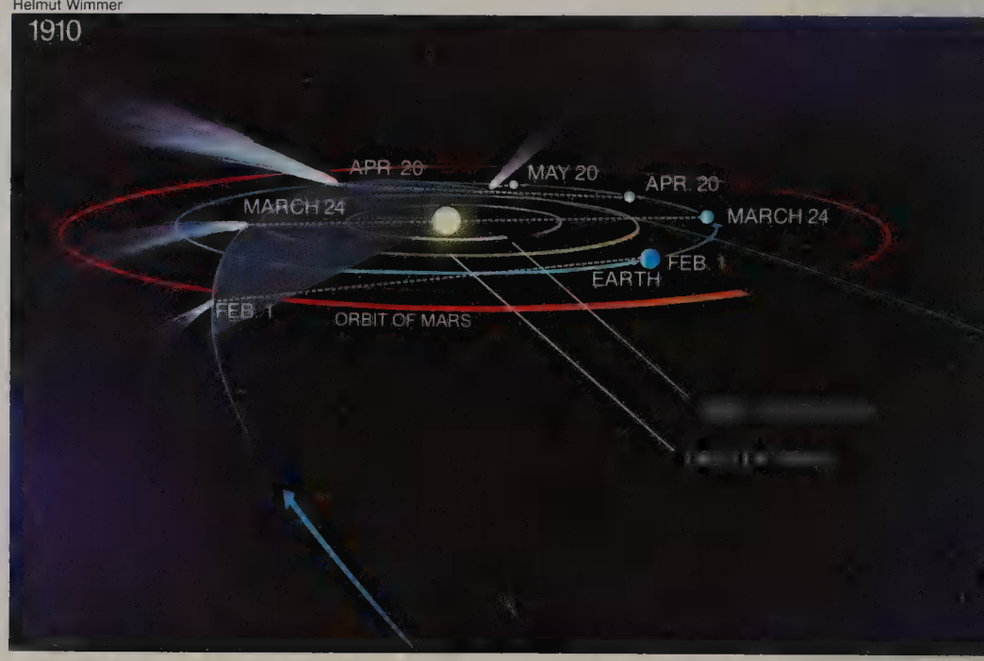
November 22: The sun moves east past Saturn. After coming in line with sun, the planet becomes a morning s

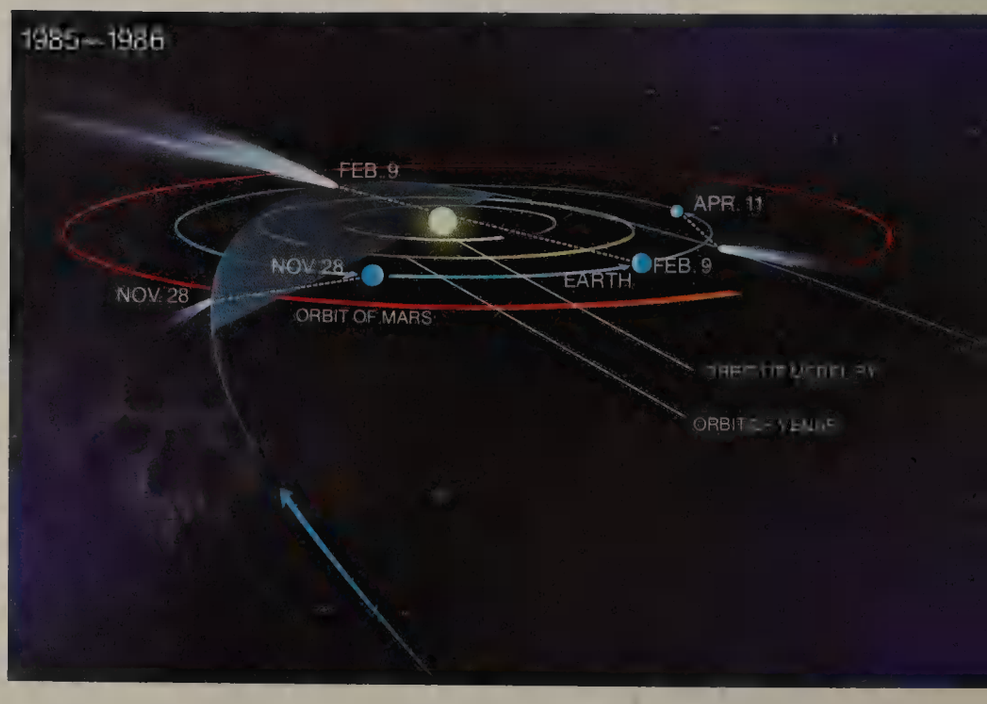
November 24: Sheratan and Ha the two bright stars of Aries the Ram above the moon tonight after it moves the constellation.

November 25: Apogee moon (fart from Earth) is still in Aries.

November 26: The gibbous moon ters Taurus again, where it was at the ginning of the month. The Pleiades

Helmut Wimmer





Sisters) are slightly above it and be dimly visible through the 's glare.

vember 27: The closest preperi- n passage of Comet Halley with n occurs today at a distance of 57 mil- miles. The comet is now closest to n on its journey toward the sun; an- (still closer) approach occurs in after perihelion. The comet is west moon, above the bright stars of Ar- The glare of moonlight, however, es the comet impossible to see with aked eye.

ovember 28: Mercury is in inferior unction, passing between Earth and un and entering the morning sky.

ovember 29–30: The bright gibbous n ends the month in Gemini, drifting r to Pollux and Castor on these eve- s, rising shortly after sundown and re- ing in the sky past dawn.

Halley's Comeback

ovember is an important month in the et Halley calendar. The comet passes e milestones in its journey toward the it moves north of the ecliptic plane on ember 9, comes closest to Earth on ember 27, and moves inside Mars's on November 28. Most important of the first "window" in its viewing dule begins, the one that favors thern Hemisphere viewers.

ost of the solar system's visible ele- ts (sun, planets, gas, and dust) are entrated near the ecliptic (the plane hich Earth orbits the sun). Most ob- move around the sun (and rotate) in ame direction, easterly (that is, coun- ockwise), as viewed from above h's North Pole. Some comets are out- ding exceptions.

ll comets that have been observed are lar orbits; their paths show no prefer- for the ecliptic plane. Except for a dred or so short-period comets cap- d in the inner solar system, the orbits hese celestial vagrants incline, essen-

In 1910 Comet Halley was fairly e to the sun when it passed the earth, diagram. That relative nearness ac- nts for its recorded brightness. This e around, bottom diagram, the comet pass the earth twice, but on neither will it be as close to either the sun or earth. That may cause the comet to ear dimmer.

Now you can own this historic commemorative of a once-in-a-lifetime event...

ACTUAL SIZE

HALLEY'S COMET COMMEMORATIVE MEDAL

Minted in solid sterling silver by The Franklin Mint

Issued in a Limited Edition. Advance ordering deadline: November 30, 1985.

It was last seen in 1910 ... and it won't be seen again until the year 2061.

But *you* can see it this year!

It's Halley's Comet. The celestial event of the century. And a once-in-a-lifetime experience.

To celebrate this spectacular event, The Franklin Mint will strike a special limited edition medal—so that you may preserve this memorable occasion for today and for future generations.

Halley's Comet Commemorative Medal will be exceptionally large—39mm in diameter—and will be minted in solid sterling silver. The face will portray Halley's Comet as it streaks across the surface of the earth. The reverse will show the comet's orbit through the entire period of its sighting, month by month, moving ever closer to us.

This magnificent medal is an original design by the master sculptors of The Franklin Mint, and will be struck by the mint's engravers and craftsmen. Each medal will be accompanied by a Certificate of Authenticity and a fascinating reference folder.

To show the medal to best advantage, it will be sent in a handsome display stand. The issue price for this solid sterling silver medal with a frosted *proof-quality* finish, is $37.50.

This important commemorative medal will be issued in a strictly limited edition. It is being offered *only* until April 11, 1986, the date Halley's Comet comes closest to the earth. After that, it will never be made available again.

Advance orders are being accepted until November 30, 1985. To acquire the medal—to share with your family and keep as a lasting remembrance—please mail your order to The Franklin Mint, Franklin Center, PA 19091, by November 30, 1985.

© 1985 FM

ADVANCE ORDER FORM

HALLEY'S COMET COMMEMORATIVE MEDAL

Valid only if postmarked by November 30, 1985.

The Franklin Mint
Franklin Center, PA 19091

Please send me ____ (QTY) of the Halley's Comet Commemorative Medal (39mm), to be minted in solid sterling silver with a *proof-quality* finish. The issue price is $37.50* per medal. (Display stand included at no added charge.) **Plus my state sales tax and $1. for shipping and handling.*

I prefer to pay as follows:

☐ DIRECTLY. I enclose $_____ as payment in full.

☐ BY CREDIT CARD. Bill the total amount of $_____ to my credit card, after shipment.

tially at random, all over the lot. They are as likely to move westerly as not. Thus it isn't surprising that Comet Halley curves toward us from a direction opposite that of Earth's revolution about the sun and on a tilted orbit.

For most of each solar journey, Comet Halley is well south of the solar system's principal plane. When farthest from the sun, it is 930 million miles south of Earth's orbital plane (ten times Earth's distance from the sun). It eventually crosses north of the plane on November 9, where it spends only 121 days of its 27,700-day orbital journey, climbing less than 16 million miles north of the ecliptic plane before returning south again on March 10, 1986.

On the way in from the outer solar system, Comet Halley moves past the orbits of seven planets, having started its present journey from beyond distant Neptune in 1948. It passed inside Neptune's orbit in the early 1960s, that of Uranus in 1977, Saturn's in 1983, and Jupiter's only ten days into 1985. Speeding up on its way in (now flying sunward at about 56,000 miles per hour), it still took more than ten months to reach Mars's orbit on November 28. Yet to come are Earth's orbit, which the comet will pass on New Year's Day, 1986, and that of Venus (January 20, 1986), before the comet "turns the corner" on February 9 to move away from the sun once more.

Each time Comet Halley goes round on this journey, it encounters Earth (moving in its own orbit) in different circumstances. Depending on where Earth is located, one or two points may occur during each comet journey when Earth and the comet come nearest to one another.

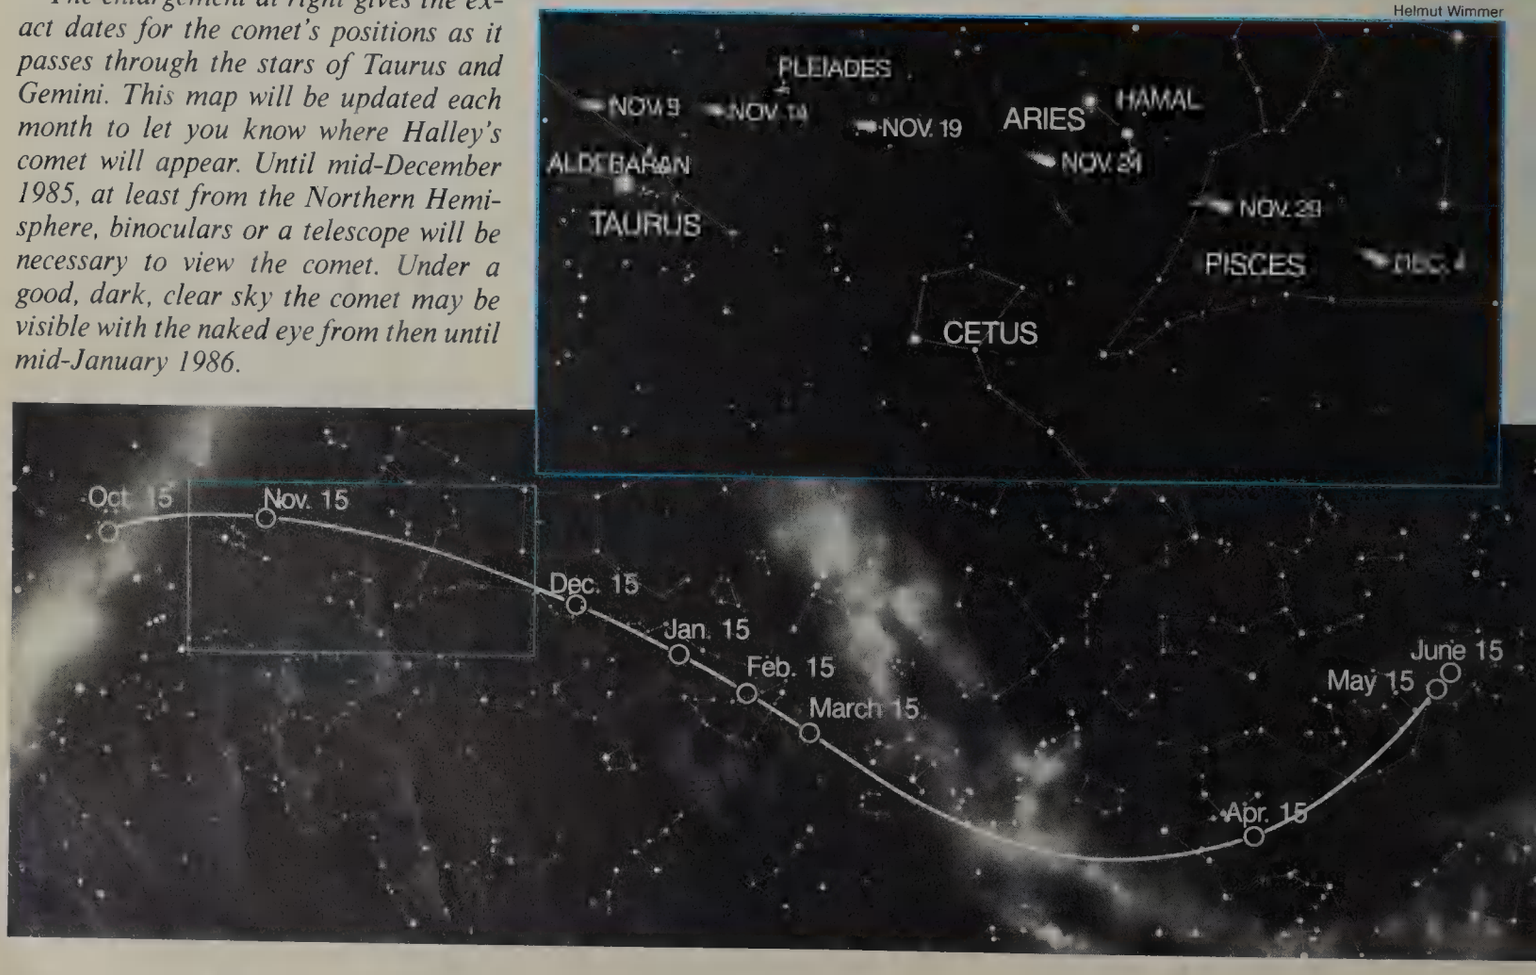
In 1910, Earth came within 14 million miles of Comet Halley less than a month after the comet had passed the sun. This single passage of the comet past Earth while it was still relatively close to the sun accounts for the comet's brilliant appearance that year. But the 1986 orbit of Comet Halley will encounter Earth quite differently. The comet passes close to Earth twice, once on the way in (November 27, at 57 million miles distance) and once on the way out (April 11, 1986, at 39 million miles distance). Both times the comet will be relatively far from the sun as well as from Earth, as compared with 1910. At or near the comet's perihelion on February 9, when it is brightest, Earth will be on the opposite side of the sun as seen from the comet.

On our close approach to the comet on November 27, Comet Halley will not have much of a tail, but it will be bright enough to be seen easily with binoculars. Thereafter, Earth and comet separate. As the comet approaches the sun it will continue to brighten, but at the same time its distance from the sun in the sky will decrease; thus the comet will spend fewer dark hours above the horizon. By mid-January, it will simply be too low at dusk to be seen no matter how bright it becomes.

From now until the middle of December, binoculars or telescopes will be needed. From then until mid-January, if conditions are good, sharp-eyed viewers should be able to pick out the comet in the evening sky with the unaided eye. This means clear, dark skies—no local lights or city glow, no obstructions in the western sky, and no moonlight. From the latter point of view, the best viewing periods will be from about November 30 to December 15 and again from December 31 to about January 15. At other times, the early evening moonlight will be an interference.

The diagram, below, traces Halley's path from left to right as it moves across the sky. The circles and dates indicate where the comet will be on the fifteenth of each month until June 1986, when it will have completed its journey around the sun. The comet will continue to fade from view, returning to interplanetary space.

The enlargement at right gives the exact dates for the comet's positions as it passes through the stars of Taurus and Gemini. This map will be updated each month to let you know where Halley's comet will appear. Until mid-December 1985, at least from the Northern Hemisphere, binoculars or a telescope will be necessary to view the comet. Under a good, dark, clear sky the comet may be visible with the naked eye from then until mid-January 1986.



THUMB YOUR WAY AROUND THE WORLD.

ou could go around the world (the hard way) never come across an Atlas like the Hammond d Medallion.

or openers, it's the only published Atlas with mb indexing—so you open to the area you want hout flipping through pages you don't want. hen this Atlas practically takes you by the hand he exact location you're looking for. Because erever there's a map, they've put an index. (Of rse, there's a huge master index in the back.) 's as easy as using a dictionary—and there are e facts and figures inside than there are words dictionary. On everything from politics, nomics and culture to rainfall and average peratures.

Not to mention 650 colorful maps, charts and phs. And a U.S. History, a World History and ble History Atlas also between its covers.

What's more, this is 1st class travel (and a 1st s gift). The Gold Medallion is in bonded her, brilliantly gilded all around and covered n a clear plastic jacket—to protect it through all years of good use it will get.

And it's the perfect time to start using this Atlas. It's $67.50 to museum members (that's 10% off, it's normally $75). And for $5.00 more, you can have your name—or the name of the lucky person you're giving it to—embossed in gold on the cover.

All in all, this is one offer you'll say thumbs up to.

Dr. Leipoldt's Afrikaner Cookery

The gap between whites and blacks turns up even in a classic cookbook

by Raymond Sokolov

I have recently come into possession of *Leipoldt's Cape Cookery,* a scholarly account of Afrikaner cuisine, a hybrid of the very colonial culture now facing what may be its ultimate crisis. The author, C[hristiaan Frederick] Louis Leipoldt, was a prominent figure in South African life—a leading physician, a poet in both Afrikaans and English, a popular quiz-show personality on radio, a pundit, and a curmudgeon.

Born in 1880 in a remote mission station in Cape Colony, Leipoldt developed into an intellectual and a man of the world. The American press magnate Joseph Pulitzer once retained him nominally as his physician but really as a companion on his yacht. But Leipoldt did not turn his back on the Cape. And when he returned home from Europe in 1914, he resettled there, essentially for life.

Cooking, especially the traditional cooking of Cape Colony, became one of his chief preoccupations. He collected manuscript cookbooks and pored over early printed collections of recipes. Leipoldt made no claim and no serious attempt to be an anthropologist among the Zulu and Xhosas cooks of South Africa. He was interested in the food eaten by his own people in his own section of the country, where colonists adapted European food ideas, mainly those current in the early nineteenth century, to South African plants and animals and to the exotic methods of their Malay-run households.

Leipoldt published a cookbook in Afrikaans, *Kos Vir Die Kenner,* while he was alive, but he left a separate manuscript in English when he died in 1947. That manuscript was first published in 1976 and reprinted in 1983. Although the recipes did not pass through the hands of a home economist and do not list precise quantities of ingredients or specify cooking times or yields, it seems unlikely that Leipoldt's elegant little book will ever be surpassed as a record of a peculiar and fascinating frontier cuisine. Few people of Leipoldt's capacities have ever troubled themselves to write about food. He was, moreove witness, albeit a late one, to the flower of Cape cookery, and lived to see it star fade at the end of World War II. (Toda is experiencing a revival.)

Cape Cookery has a special interest American readers because it investiga and documents a colonial cuisine inven by and for colonizers in a rural soci where the white, European few domina the nonwhite, non-European many, b indigenous (blacks) and imported (M lays). In reading Leipoldt, Americans v inevitably think of the cuisine of the ar bellum South. Here we had the same c ative collision with new ingredients, same European culinary structure, same openness to new ideas from n white cooks.

The parallels cannot be carried mu further, certainly not politically. And terms of cuisine, we seem to have enc up with a heavy African admixture in c food, although the indigenous America were originally Asiatic, while the Afri ners adopted the spicy sambals of Sou east Asia, without taking much account native African recipes.

Nevertheless, white Americans will r ognize Leipoldt's admiring, but mora naïve, paean to his Malay "mammy":

My interest in cookery dates from the ti when, as a little boy in the late eighties the last century, I assisted in a very mi and suppressed capacity, at the culinary c erations of a very expert Colored wom cook who bore the reputation of being c of the best in the Cape Colony. Fat to t verge of obesity, she presided over a kitch whose cleanliness could have served as model for an operating theater of a mode hospital, largely because she insisted th punctilious, painstaking ablution was an dispensable preliminary in the preparati of food. Her inculcation of these eleme tary principles, often accompanied by good-natured but nevertheless pain prodding of my juvenile person with t large wooden spoon that was her scept helped me—in later days when I learned better my taste and broaden my expe

ence—to realize how any infringement of them inevitably impairs the excellence of all cookery.

The ayah's art was the result of many years' instruction and experience in the traditional methods of Malay cookery, whose outstanding characteristics are the free, almost heroic, use of spices and aromatic flavorings; the prolonged, steady but slow application of moist heat to all meat dishes; and the skillful blending of many diverse constituents into a combination that still holds the essential goodness of each. Her dishes, which were eaten by governors, prime ministers, and very important persons, were made from old recipes that were firmly enshrined in her memory, for she never referred to written or printed directives.

Anyone wanting to get an idea of how the tropical Malay touch broadened and spiced the homelier, blander cuisine of northern Europe brought to Africa by the austral vanguard of the Dutch Reformed Church should take a look at Leipoldt's recipe for Jerusalem artichoke and banana or at his quince sambal (see below).

These recipes show the Asian ayah at work, turning the Mediterranean quince into a pungent relish and mixing the humble, earthy, crunchy Jerusalem artichoke with mushy, sun-yellow banana. All of this is as surprisingly un-African as okra gumbo—with its African beginnings—is un-American at base.

Leipoldt definitely strives to give the impression that Cape cookery is an imported hybrid: one part Dutch or Germanic with English infusions; the other Malay or "Oriental." Biltong, South Africa's famous jerked, or air-dried, meat, is traced to its Dutch origin as tassal. "O ental influence," he writes in his ch ter about the origins of the Cape cuisi "was predominant." Hildagonda Johar Duckitt, the South African Mrs. Beet spent her Victorian youth on a farm wh the cook was "an East Indian, an adept making curry and Malay dishes." M Duckitt's extremely influential bo *Hilda's Where is It?* contains, by L poldt's count, fifty exclusively South A can recipes, which "show the influence Oriental cooking methods, combined w local ingenuity in blending flavors and hancing the savor of the dish." But M Duckitt unaccountably failed, Leipo says, to include any recipes "manuf tured from ingredients that are essentia local—such as water hawthorn stew a the purées made from veld plants."

Nowhere in this chapter on the orig of Cape cuisine is there any mention "local" people, in Leipoldt's sense of t word. No black Africans play Squanto the sixteenth-century Dutch East In Company pilgrims, and blacks rema mysteriously absent from the book as whole. It is true that in Leipoldt's regi the Southwest Cape, blacks are even day a minority, but he shows no inter whatever in indigenous Hottentot fo Then again, perhaps the colonists stu bled on water hawthorn stew all on th own, not to mention the other wild and European, un-Asian, purely local fo that Leipoldt loved most.

Here he is, in his best, high-aesthet nostalgic vein, lamenting the passing o certain market in Cape Town:

In that cool, inviting colonnade, one co

Three Recipes from *Leipoldt's Cape Cookery,* by C. Louis Leipoldt
(W.J. Flesch and Partners, P.O. Box 3473, Cape Town 8000, South Africa)

Quince Sambal

Peel and grate a ripe quince. [It] should be snowy white.

Mix the grated flesh with lemon juice, powdered chili and white pepper and a little salt.

Porcupine Cracklings

Plunge the animal, as you would a suckling pig, into boiling water; scrape off the pens and the hairs; scrub the skin until it is perfectly smooth and white. Now skin the animal and discard the meat, which is not very nice to eat. Put the skin in a jar in salt water to which you have added a little vinegar, and let it lie in it overnight. Take it out the next day, dry it, rub it with a clove of garlic and put it in a saucepan with a little boiling water. Boil till it is tender enough to allow a fork to pierce it easily Take it out and cut it up into pieces abou the size of flattened apricots (about inches square) which you may either gri or fry in a pan with a little fat. Put on th pieces some pepper and salt and send t table with plenty of rice, and lemons cut i halves.

Banana Artichokes

Dice some [Jerusalem] artichokes tha have been steamed in wine; put the piece of artichoke in a saucepan, slice on then the bananas; add a lump of butter, a littl salt, pepper, and parsley; let them simme for a few minutes; add a glass of sherry and a little flour to thicken; shake well an add some more salt if required, and finall a cup of boiling thin cream. Serve wit nutmeg grated over.

most anything that one could think of
e kitchen—out-of-the-way herbs, tor-
and turtles; the tasty little "klip fish";
romatic berries that came from bushes
ing on the edge of the Green Point
mon Lake; the succulent fennel roots
made such delicious preserve; the de-
ful, but rather vulgar, rose apples that
folk liked to mingle in their sweet
es; the immense crayfish [langoustes or
lobsters] (the like of which one no
er sees, since Government has taken
under its protection and tried to teach
o call them crawfish); malagas eggs
re tasty than those of the penguin);
even that most delectable of all delica-
the prepared skin of a porcupine. [See
pe.]

is, of course, theoretically possible
none of these things was first discov-
by native Africans and passed on to
nists. But I doubt it. I especially doubt
the case of porcupine cracklings. And
e is the even more glaring case of
kos, wild food from the veld, that is,
a wild or uncultivated part of the
ntry.

Nothing could be more "local" than
e tubers and berries, these bulbs and
s. Can it be that their culinary use was
ned in every case by some clever Euro-
forager or by Malay slaves in their
-found land? This is the impression
oldt gives. Perhaps this happens be-
se in his scholarly way he limited him-
to written sources that ignored aborig-
cookery and food knowledge. And, of
rse, it may be that such substances as
(the seeds of the wild almond, *Brabe-
stellatifolium*) were independently
upon by natives and by colonists as
th roasting and then brewing into a co-
ike beverage called ghoo coffee. One
es, nevertheless, an omission here.
re are surely ways of looking beyond
ted sources and deducing which wild
ds were traditional in southern Africa
ore the advent of the colonist. It would
be interesting to know the modern so-
ogy of these indigenous foods. Who,
instance, were the workers in the road
gs at Grey's Pass, who allegedly, in
oldt's account, "lived mostly on ghoo
ns and a wine ration and did better
k than anyone else"?
might be persuaded that nothing men-
ed by Leipoldt in his charming and
ful book was eaten by black Africans
ore contact with Europeans. But then,
at did native Africans eat that was
quely theirs and why did Leipoldt ig-
e the subject?

*ymond Sokolov is a writer whose spe-
interests are the history and prepara-
of food.*

BIG BAND SWING VIDEOS

Original Video Rhythms of the Big Band Era!

All on one full-length video cassette!

ONLY $19.95 and NOT available in stores!

What was it about the Big Bands that captured the ears and hearts of Americans so many years ago? Why do they sound as great today as they did way back then? For the lowest price ever, you can put away those scratchy 78's and watch the Big Bands swing into action, exactly as they were filmed in the 1940's. The entire collection is yours for only $19.95 plus shipping and handling. Order today and we'll send you our giant video catalogue absolutely **FREE!**

Listen and watch **LOUIS ARMSTRONG** blow off the roof, **GENE KRUPA** beat it out, **FATS WALLER** tickle the ivories, **CAB CALLOWAY** "hi-de-ho" up to Harlem, **COUNT BASIE** and **LIONEL HAMPTON** swing out, **JIMMY DORSEY, LARRY CLINTON,** and **STAN KENTON** front their Big Bands and many more!

Our complete catalogue $1.75. Sent FREE with your order.

Up in Ontario

As a lumberjack, Wayne Lankinen generally focuses more on the trunks of trees than on their upper branches. But when Lankinen spotted a marten in a jack pine he was about to cut, he dropped his power saw and ran for his camera—telling the other jacks to keep the marten there until he got back. The marten, temporarily up a tree, started exploring the place and soon discovered a fellow inmate—a squirrel—above it. There was a brief chase; but by the time Lankinen got back, the marten had done to the squirrel what the lumberjacks had done to the marten—and everybody was trapped.

Actually, Lankinen was a little surprised to see a marten at all. They are rare in his part of Canada—the Thunder Bay section of Ontario—as they are in many places in the northwestern United States, Alaska, and Canada. The American pine marten used to be called American sable, and the creature was trapped intensively during the nineteenth and twentieth centuries. By the 1940s pelts were bringing as much as $100 each, but populations were way down. Regulations to protect the animal helped its population recover in many places. In some spots, however, it is gone for good.

The marten lives in pine forests. A relative of weasels, minks, and ferrets, it builds dens in hollow trees or logs. The marten is partly arboreal, although it spends a lot of time on the ground. It lives on small mammals, birds, insects, and fruit.

Lankinen got back in time to get this shot of the marten's encounter with the squirrel, which ended a few minutes later when the mammal population of the jack pine was reduced by one. Lankinen, who is interested in animals' habits, not their hides, had no such fate in mind for the marten. Once he had taken the photos he wanted, he left the jack pine alone. It was the last tree in its row, and the marten eventually scrambled down from it and chased after the woods—which had retreated a little bit just in the course of the morning.

WANTED

A Nationwide Search By The Bontany Department at the University of Vermont

The Botany Department is searching for high-quality, serious, field-oriented students to enroll in a unique Master's degree program in Field Naturalism.

Complete fellowship support is available to FIVE very serious students with strong science backgrounds, willing to give their full time and effort for a 2-year rigorous program.

Deadline: March 1, 1986

Contact: Dr. H.W. Vogelmann, Chairman, Botany Department
University of Vermont
Burlington, Vt. 05405 (802) 656-2930

FACES
The Magazine About People

Exciting new magazine for children! FACES: The magazine about people—all over the world! From China to Peru, FACES explores the world of people, anthropology, archeology, and far away places for children 8 to 14 years old! An unusual magazine for unusual children. Published by Cobblestone with the American Museum of Natural History. To order (or give a gift) send $16.50 to FACES Magazine, Room 2, 20 Grove Street, Peterborough, NH 03458. Museum Members entitled to $2.50 discount off subscription price!

Additional Reading

Klipspringers and Monogamy (p. 40)

For a comparative review of the ethology and behavioral ecology of klipspringers and other hoofed mammals of Africa, see W. Leuthold's *African Ungulates* (Berlin: Springer-Verlag, 1977, vol. 8 of the Zoophysiology and Ecology Series). Robin Dunbar discusses the significance of fidelity and long-term pair bonds in "The Ecology of Monogamy" (*New Scientist,* vol. 103, No. 1419, pp. 12–15). When they encounter predators, klipspringer male-female pairs deliver a specialized alarm call in duet. Ronald L. Tilson and Peter M. Norton report on their research on this warning signal in "Alarm Duetting and Pursuit Deterrence in an African Antelope" (*American Naturalist,* vol. 118, pp. 455–62). Tilson explores the animal's methods of dealing with predators in "Klipspringer Social Structure and Predator Avoidance in a Desert Canyon" (*Journal of Madoqua,* vol. 11, pp. 303–14).

Ross's Metalmark (p. 48)

The first description of Ross's metalmark was published in 1964 by Harry K. Clench, who named the butterfly after Gary N. Ross: see "A New Species of Rioginidae from Mexico" (*Journal of Research on the Lepidoptera,* vol. 3, pp. 73–80). Ross wrote the two important articles on the species' life history: "The Ecology and Ethology of *Anatole rossi,* a Myrmecophilous Metalmark (Lepidoptera: Rioginidae)" (*The Annals of the Entomological Society of America,* vol. 59, pp. 985–1004) and "Early Stages of *Anatole rossi,* a New Myrmecophilous Metalmark" (*Journal of Research on the Lepidoptera,* vol. 3, pp. 81–94). H.E. Hinton's "Myrmecophilous Lycaenidae and Other Lepidoptera: A Summary," published in 1951 (*Transactions of the South London Entomological Natural History Society,* 1949–50, pp. 111–75), continues to be the definitive general description of ant-caterpillar relationships. Both W.M. Wheeler's *Ants: Their Structures, Development and Behavior* (New York: Columbia University Press, 1910) and A.B. Klots's *The World of Butterflies and Moths* (London: George G. Harrap and Co., Ltd., 1958) have small but good sections on ant-caterpillar interrelations (see pages 339–60 in Wheeler and 138–42 in Klots). Wheeler's book continues to be the standby in the field, despite its age; Klots's study is also a primary source of reference.

Spanish Village (page 68)

Ruth Behar's *Santa María del Mo* scheduled to appear from Princeton University Press, Princeton, in the spring 1986, is a detailed study of the traditional agricultural life styles of peasant farmers in a small Leonese village. *Neighbors: The Social Contract in a Castilian Ham* (Chicago: University of Chicago Press, 1970), by Susan Tax Freeman, highlights the importance of communal agrarian traditions in the Spanish countryside. For discussion of the recent transformation of Spanish rural life, see Carmelo Lisón Tolosana's *Belmonte de los Caballeros: Anthropology and History in an Aragonese Community* (Princeton: Princeton University Press, 1983); the larger, national picture is provided in Joseph Aceves and William Douglass's *The Changing Face of Rural Spain* (Cambridge: Schenkman, 1976). Susan Harding's *Remaking Ibieca: Rural Life in Aragon under Franco* (Chapel Hill: University of North Carolina Press, 1984) concentrates on the long-term effects of agrarian reform on the life of a Spanish farming population. For a general treatment of the social, economic and cultural life of peasants, see Eric Wolf's *Peasants* (Englewood Cliffs: Prentice-Hall, 1966); for a historical overview see D. B. Grigg's *The Agricultural Systems of the World: An Evolutionary Approach* (London: Cambridge University Press, 1974). Dorothy Hartley's *Lost Country Life* (New York: Pantheon, 1979) reconstructs of the agrarian life cycle in old Europe. Also relevant are M. Redcliff's "The Future of Agriculture in a Spanish Pyrenean Village and the Decline of Communal Institutions" (*Ethnology,* vol. 12, pp. 193–202) and Robert McC. Nutting's "What Alpine Peasants Have in Common: Observations on Communal Tenure in a Swiss Village" (*Human Ecology,* vol. 4, pp. 135–46).

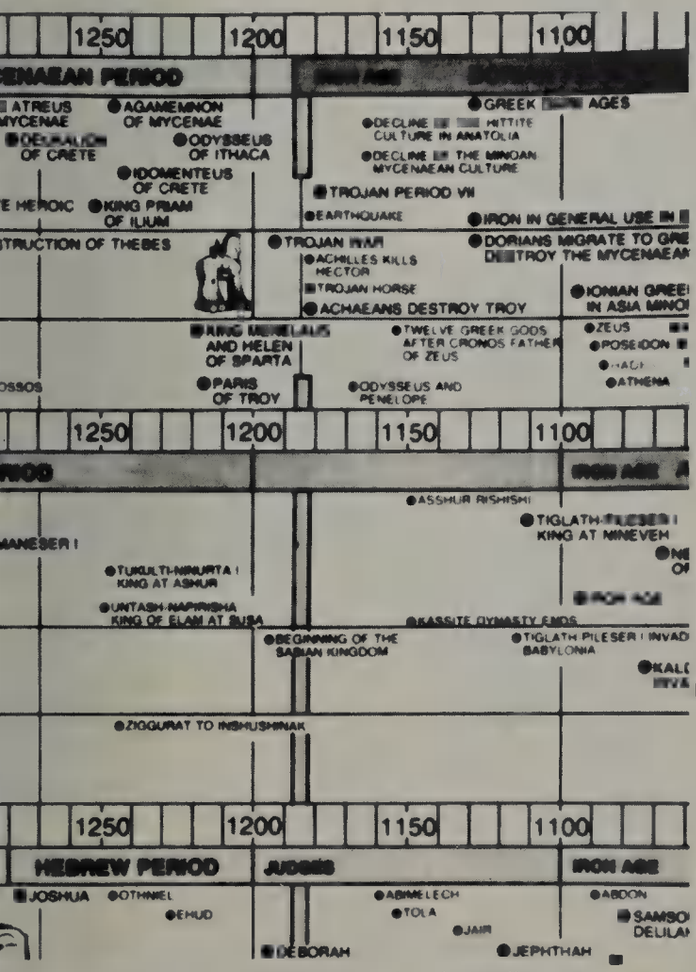
History comes alive. On The History Chart.



istory shown in this block is all contained in the small square ated on the chart above.

art is produced in full color.

If you think history is just a collection of dry facts, you should send for The History Chart today. Because The History Chart (34 inches high and 8 feet long!) is a fascinating 6000 year chronology of the world's people and events to the present day. To understand the wealth of information contained in the Chart, the history of the United States is only 2 inches old over 8 feet of time.

Just ask yourself the following questions. Who came first, the Romans or the Vikings? Did the Babylonian Captivity of the Jews pre-date the Athenian Republic? Who brought the Greek gods to Egypt?

If you don't know (or even if you do), you'll find that The History Chart is a uniquely enriching educational experience for everyone. The History Chart has been on display in the Library of Congress.

There's no better way to see the panorama of human history, archaeology, theology and mythology than The History Chart. It even includes suggestions for further reading.

So fill out the coupon (or write on a separate piece of paper) and send it with your check or money order for $19.95 (plus $5.00 for shipping and handling) today. You'll soon be enjoying history as you never have before.

Please send me The History Chart. Enclosed is my check or money order for $24.95 (which includes $5.00 for shipping and handling). Add $15 for laminated Chart.

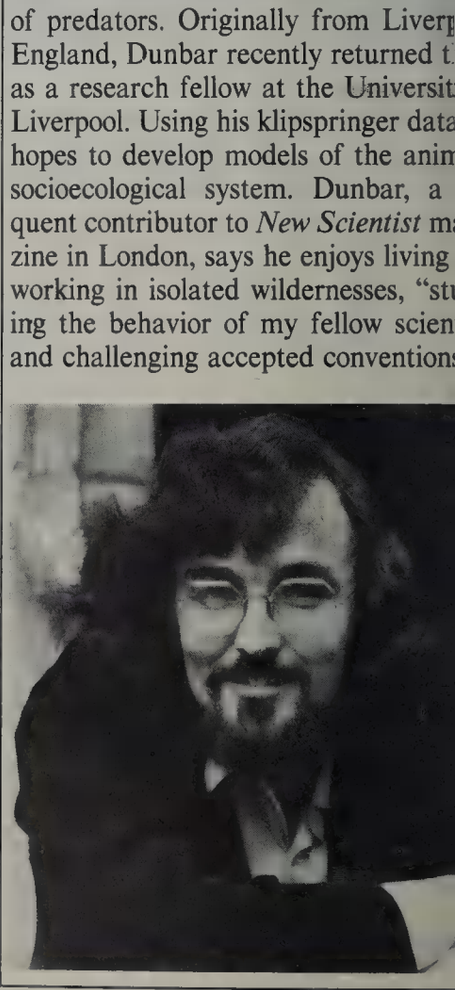
Authors

In the summer of 1984, **Ruth Behar** (page 68) returned to the Spanish village where, three years earlier, she had completed fieldwork for her doctorate in anthropology. Behar (left) found that in her absence a land consolidation program had begun to erase community relations and agricultural practices that had survived from medieval times. In her article in this issue, she describes how government engineers did not anticipate all the consequences of altering the ancient pattern of land ownership. Currently a Rockefeller Residence Fellow in the Atlantic Program at The Johns Hopkins University, in 1986 Behar will become an assistant professor of anthropology at the University of Michigan. Her most recent research has been on witchcraft, magic, and male–female relations in colonial and contemporary Mexico. Her future plans include studying a religious revitalization movement in northern Mexico and southern Texas and continuing to document changes taking place in rural Spain.

When he began his graduate work in biology at Louisiana State University in 1962, **Gary N. Ross** (page 48) went on a six-month expedition to investigate butterfly populations in Mexico's relatively unknown Sierra de Tuxtla. Little did he realize that he would discover a new species in the process. This butterfly, named Ross's metalmark in his honor, became the subject of his master's thesis and is the basis of his article in this issue. His doctoral dissertation dealt with all of the region's butterflies. Ross has also done fieldwork elsewhere in Mexico and in Central America. At present, he is studying the natural dyes and biological motifs used in the weavings of the Zapotec Indian culture of Oaxaca, Mexico. Recently he arranged for a major exhibition of these textiles in Baton Rouge, Louisiana, where he is professor of biology at Southern University.

While studying the social biolog gelada baboons in Ethiopia, **Robin Du** (page 40) became interested in the s antelopes darting shyly about his s site. Klipspringers, he learned, were ally paired off, and their fierce fideli each other made him wonder about nogamy. As he reports, the klipspri bond is founded not on love but on the of predators. Originally from Liverp England, Dunbar recently returned t as a research fellow at the Universit Liverpool. Using his klipspringer data hopes to develop models of the anim socioecological system. Dunbar, a quent contributor to *New Scientist* m zine in London, says he enjoys living working in isolated wildernesses, "stu ing the behavior of my fellow scien and challenging accepted convention



Some naturalist-photographers started out as school teachers and later yielded to a stubborn artistic impulse. Others—perhaps those enamored more with the technology of photography—have backgrounds in electronics. But a lumberjack? "I just saw all these nice pictures around," says **Wayne Lankinen** (page 108), who runs his own woodcutting company in Pearson Township, Ontario, Canada, "and I thought I'd give it a try." Apparently it's been a nice try: Lankinen, who lives in the area where he was born and does the work his father did, is selling more and more photographs and feels creasingly involved with his second car He certainly spends enough time in field, five or six days a week, cutting p lar and jack pine into eight-foot-l blocks, which he sells to the local pa company. He does his work on gov ment land designated for logging. "I handle a power saw a lot," Lankinen s "and there's still lots to do. But I'm th ing of doing photography full-tim Lankinen was logging when he ca across the marten featured in this mon "Natural Moment."

THE NEW SAAB 9000 HAS ACHIEVED AN IDEAL BALANCE 75% SPORTS CAR AND 75% LUXURY SEDAN.

You've driven in a sports car. Remember the way it hugged the road? The way it took the turns? The way it accelerated? The way you fel

(You could accept the negatives, such as comfort which approximated that of the front seat on a roller coaster.)

You've also driven in a luxury car. Remember the legroom? The sto age space? The relaxing seats? The way you felt?

(You could also accept the negatives, such as the fact it drove like the Queen Mary.)

Saab asks you not to accept negatives. Rather, add up the positive of both aspects of the new Saab 9000.

On the sports car side, there's performance in the form of a 16-valv intercooled, turbocharged engine that takes a car from 0 to 60 in hardly any seconds and maintains speed and fuel efficiently for hours on end.

A suspension with McPherson struts that sits a Saab 9000 on a road as if car and asphalt or car and macadam or car and dirt were one.

The steering, of course, is rack-and-pinion, so the driver can't hel feeling and knowing what's happening between the tires and the road.

The brakes are large-diameter discs, power-assisted and, with a dual-circuit system, almost "fail-safe."

On the luxury sedan side, there's Automatic Climate Control. You

your Saab 9000 what temperature makes you feel the most chipper
it, through microprocessors, keeps you happy.

Size: People in government (the EPA) charged with such things
e declared the Saab 9000 a "large" car.

Considering the legroom, the elbowroom, and the carrying space
to 56.5 cu. ft.) that may even be a mite bit of an understatement.

The touches: Seats
a steering wheel that
ust to even the most
raordinary anatomy.

Instruments within
r reach and so well-
ught-out that your
s, so used to being as-
lted on the road, will
ne to appreciate the soothing green illumination.

The exterior? Well, check the pictures on these pages for a few sec-
ls. Then see a new Saab 9000 for yourself at a Saab dealer, where a
fect balance always exceeds the sum of its parts.

The most intelligent cars ever built. SAAB

Symbiosis Unabashed

As an unabashed enthusiast of the protists (protozoans, algae, and the like), I was disturbed by the introduction to O. Anne Rasa's otherwise interesting article on dwarf mongoose/hornbill mutualism (September 1985). Particularly jarring was the assertion that "mutualistic relationships that cross taxonomic class lines are especially rare." In fact there are few, if any, animals or protists that do not harbor bacterial, viral, and/or protistan symbionts. Examples range from the metabolically vital zooanthellae and zoochlorellae of coral reefs to the darling of molecular biologists—the bacterium *Escherichia coli,* which is part of our normal gut flora.

Nor is symbiosis foreign to either plants or fungi. The roots of most groups of vascular plants rely on their associated mycorrhizae (literally "fungus roots") for the uptake of essential elements like phosphorus. In turn, the fungi receive organic carbon from the associated plant. Of course the finest example of plant/fungal symbioses is the lichens.

Finally, the nineteenth-century proposal that mitochondria and chloroplasts originated as prokaryotic symbionts has many adherents. If mitochondria did originate as symbionts, every cell in our bodies harbors a very ancient symbiont.

Bamboo Shoots

Although I have not been to Japan and have not observed the weekend dancing in Yoyogi Park described by C. Scott Littleton in "Tokyo Rock and Role" (August 1985), I must react to some of the comparisons made with American and specifically southern California youth gangs.

As a correctional educator, I work daily with youths who are members of gangs in East Los Angeles. These gangs are not lacking in organization, show both loyalty to senior members and to group values, and can generally be described as fastidious in their appearance. In these characteristics, they are more analogous to the Wild Drivers and Bamboo Shoots than Mr. Littleton may suppose.

Group loyalty, deference to senior members, a tidy appearance, and an organizational structure are as much a part of American youth gangs as they are characteristics of Wild Drivers and Bamboo Shoots. These cross-cultural comparisons should be noted as clear similarities.

Food Chain: Who's on Top?

The solution to the problem of the "Lake Bottom Tyrant" (August 1985) is so obvious, I am surprised that none of the learned men and women who are studying this crawfish problem have come up with it yet.

Since the rusty "crayfish" (as the rest of the country refers to what we know as crawfish) is at the top of the food chain in their Wisconsin lakes, the only logical thing to do is to put man (women and children) at the top of the food chain. This can easily be done by sending several Cajun families from southern Louisiana to Wisconsin: The rusty crawfish population will decrease rapidly. We Cajun know 102 uses for crawfish, about 100 being ways to eat them.

Street Children

Brian Sutton-Smith's review of *Children of the City*, by David Nasaw (October 1985) did not mention—or failed to list—one lucrative employment of the street children described in the book.

My mother, born 1887, said that one of her most vivid first impressions of life in a big city when her family moved to Philadelphia about 1900 was seeing boys fighting on the street over what they termed doggie diamonds.

She learned that these dog droppings—particularly those with a white color when dry—were sold by the boys to tanners of fine glove leather in the city. And the term doggie diamonds has remained in our family's vocabulary ever since.

Author Sutton-Smith seemed to indicate that shoeshine boys went out of fashion in U.S. cities far earlier than I know they did. My late husband, seventh child of a widowed mother, put himself through high school in the late 1920s by shining shoes and running errands that did not exclude deliveries of contraband hard liquor to prominent citizens, as well as other edge-of-the-law pursuits.

It seems to me that times and necessity make their own mores for all of us.

VERNA FORBES WILSON
Salt Lake City, Utah

OWNERSHIP STATEMENT

Statement of ownership, management, and circulation (required by 39 U.S.C. 3685) of *Natural History,* published twelve times a year at the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024, for October 1, 1985. General business offices of the publisher are located at Central Park West at 79th Street, New York, N.Y. 10024. Publisher L. Thomas Kelly; editor, Alan P. Ternes, Central Park West at 79th street, New York, N.Y. 10024. Owner is the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y. 10024. Known bondholders, mortgagees, and other security holders owning or holding one percent or more of total amount of bonds, mortgages, or other securities: None. The purpose, function, and non-profit status of this organization and the exempt status for federal income tax purposes have not changed during preceding 12 months (Section 132.122, Postal Service Manual). The average number of copies of each issue during the preceding 12 months are: A. Total number of copies printed: 540,195. B. Paid circulation: 1. Sales through dealers and carriers, street vendors, and counter sales: 6,416. 2. Mail subscriptions: 504,509. C. Total paid circulation: 510,925. D. Ambivalence in Toyland

Playthings can both isolate and socialize

by Brian Sutton-Smith

For most of us, toys are what we give children at Christmastime. Sixty percent of all toys (seven billion dollars worth) are sold during this season, and most of the rest are given on birthdays. So whatever they may have stood for in history and whatever they may tell us about human nature, toys are first and foremost Christmas presents.

All our celebrations—not only Christmas but also Thanksgiving, family birthdays, presidents' birthdays, Easter, Valentine's Day, and Halloween—have one thing in common. Originally some of these festivals were religious occasions, and in various quarters, they still are. Others celebrated the change of seasons, and their rituals were concerned with the magic of survival in the face of changes in nature. Still others were celebrations of nationhood. During this century, however, the observation of these holidays has become increasingly centered, not on widely shared cultural or religious values, but on the family.

Holidays usually reflected those parts of society where the pressures and conflicts are felt to be the greatest. Thus, in the past, when class divisions were a great burden on the lower classes, a festival was likely to be a reversal of that class division, as in the traditional Mardi Gras, in which "lowly" people pretended to be kings and queens and often shouted insults at, and even physically injured, those of higher social status. In the current, modified New Orleans festival, people dress up as royalty and toss bounty from their floats, which the crowds scramble for. What they are tossing out may be relatively worthless plastic necklaces masquerading as the crown jewels, but there remains an echo of those social divisions that, though mocked in the festival, have not changed in everyday life.

If festivals usually reveal the major conflicts in any given society, then the modern tendency of turning all festivals into family festivals could lead to the conclusion that the family is an endangered social form. Perhaps we celebrate all these family festivals because we fear that in the modern world, the family is falling apart.

By many standards the family is indeed falling apart. Three hundred years ago it was the center of most work life, most political life, most religious life, any educational life, and most reproductive life. In this century, many of these functions are attended to elsewhere—in factories, political parties, churches, schools, and family planning centers. In addition, modern society prizes individualistic ambition in school and in business. People are rewarded for putting to one side their marriages, children, families, communities, and churches in favor of the public worlds of work and success. But the giving of toys, especially at Christmastime, helps to restore the social bond between parents and children. Toys represent a bulwark against the many forces of modern society, including divorce and ambition, that threaten to tear families apart. Obviously there are many other ways in which modern families hang together, many festivals other than Christmas, and many other kinds of personal and religious dedication that serve the same purpose. But the point here is that toys are one of the contributors; one of the ways that remind family members of the "togetherness" they wish to preserve.

Paradoxically, the family that gives toys at its Christmas celebration of togetherness does not expect to spend any great amount of time with the children on whom they have bestowed these playthings. On the contrary, despite the hoped-for family bond, one of the purposes of toys is to insure that children can occupy themselves without making any great demands on the parents' time. The parent who gets down on the floor to play with a child on Christmas Day is usually doing a most remarkable thing—something seldom repeated during the rest of the year. These are, after all, busy parents committed to their work or their success in the larger society, and they do not have much leftover time in which to play with their children. Success in the modern world is generally a relatively lonely pursuit.

In modern society the rise of the toy as a child's gift can be seen as the rise of a means to accustom children to solitary preoccupation and solitary striving for achievement. One criticism of the modern toy is that it does just that—makes children too solitary and too unsociable. So does television when children watch it alone. An estimated eighty-three million American homes (98 percent) have TV, and children from two to five years of age watch it an average of twenty-eight hours per week. Those from six to eleven watch for an average of twenty six and one-half hours per week. The video game, that computer-based activity in which children spend many hours all by themselves, is only the latest of a whole series of toys and games that have been criticized for making children unsociable. Even girls' dolls and soft toys are as much a modern assuagement for loneliness as they are a training in traditional child care.

In effect the human condition has mimicked the scientific condition. The isolating we have done with atoms, we now do with individuals. The frame of mind that makes the abstractions of science possible is built up by detached and often solitary examination and inspection of the data at hand. We isolate variables in order to carry out experiments, and we isolate our thinking selves in order to be capable of carrying out experiments. We use the same analytical and impersonal processes in industry. With toys, we train childrens' minds and we habituate the children to solitary, impersonal activity. What began with Locke's blocks has been continued

The Fitness Master LT-35

TOTAL SYSTEM FOR CARDIOVASCULAR FITNESS.

Simulates cross-country skiing, regarded by fitness authorities as the top cardiovascular exercise. Rated higher than jogging, swimming, biking or rowing.

- Fluid motion — no jarring impact on bones and joints. Avoids running related injuries.
- Excellent for weight control and body tone.
- Stable, unit rests flat on floor. Lightweight for portability. Weighs only 35 lbs.
- Easily stored. Folds to 5 inch height. Slips under a bed or stands upright in closet.
- Can be used by men and women regardless of size or weight. Height and resistance adjustable.
- 30 day home trial. 2 year warranty.

WILD AMERICA IS OUR CAMPUS

Career programs leading to AA, B.S. and M.S. degrees

You can't fully learn about the environment by sitting in a classroom. Our expeditions are small groups of inquiring college, high school, graduate students and faculty who travel across America as a learning community. As we camp out September-May or summers—hiking, canoeing and skiing—we visit people and places to encounter deep ecological problems, society and self. Our 4-week to 4-year cross-cultural studies —Newfoundland to California—lead to naturalist, outdoor and educational livelihoods.

The Expedition Education Advantage. ❑ incorporates all previous undergraduate coursework, ❑ offers accredited career internships, independent study, life experience credit and transferable coursework, ❑ awards financial aid and career startup funding.

Send for complete information packet or inquire:

Students are admitted regardless of their race, sex, religion or national origin.

with puzzles, clay, trains, Erector sets, Tinker Toys, and a hundred plastic simulations advertised on television. The years of play with toys, followed by years of academic study (which has to be done largely with one's own mind going over and over material), are what lead to the expert who has within his or her head banks of information to be called on when needed. Even individuals who work in such social fields as medicine or business must develop themselves as resources, as repositories of information and skill.

There is little mention of toys in the history of play, neither in earlier historical times nor in cross-cultural studies. This is not because there were no playthings. In tribal societies dolls were constructed for little girls and bows and arrows or spears for little boys; children played with mud, twigs, and stones and made facsimile houses and cattle. But, in general, their use of objects was social, a part of teaching by adults or of play with other children. Babies had no toys, although in a few societies female adults and female children played with babies. The nature of play throughout history has been predominantly play with others, not play with toys. Today, even though children nearly always prefer playing with other children to playing on their own, they spend the greater part of their time playing alone. This is even more true of suburban children than of city children. The wealthier the children, the more likely they are to be confined to their houses and a bedroom usually stuffed with all kinds of toys. Often, the child will have no siblings or, at best, only one sibling of a different age, making satisfactory play difficult.

Our culture emphasizes childhood isolation and individuation in many other ways as well. The modern physical approach to the baby is to isolate it as much as possible from the ongoing events of family life and yet, contradictorily, to stimulate it as much as possible in order to increase its intellectual responsiveness. In this way, the general desire for solitariness is united with the desire for achievement, which is thought to require continual and intensive intellectual stimulation. The compromise is to have the stimulation carried out by physical devices that do not require the participation of another person. Every modern manual advocates that the parents themselves should stimulate and play with the child; yet no one advocates the kind of historical closeness we are familiar with, namely, that of tribes where the mother carries the baby constantly on her back, even while she works in the fields, until such time as she hands the task over to the baby's older female sibling. The modern emphasis on interaction has a much more specific focus. It is meant primarily to increase intelligence.

Perhaps it is no accident that the major topic in the scientific study of infant social development has been *attachment*. The issue is how babies become attached to mothers; how, as a result of this attachment, they begin to fear strangers and later to fear that the mother will leave them. They usually begin to demonstrate a clear preference for the main caretaker over others by about the age of five months. At about nine months they show some anxiety in the presence of strangers, and at about thirteen months, if the mother leaves them, they show some separation anxiety.

While very few psychologists have considered it instinctive, attachment has nevertheless remained the primary topic in the science of infant social development. Again, this is enlightening because the thrust of modern society has been toward detachment and alienation, rather than toward attachment and closeness. The growth of the city-state, beginning some 5,000 years ago, has led to a cumulative detachment of its members from their roots in village, religion, ethnicity, and, finally, the family.

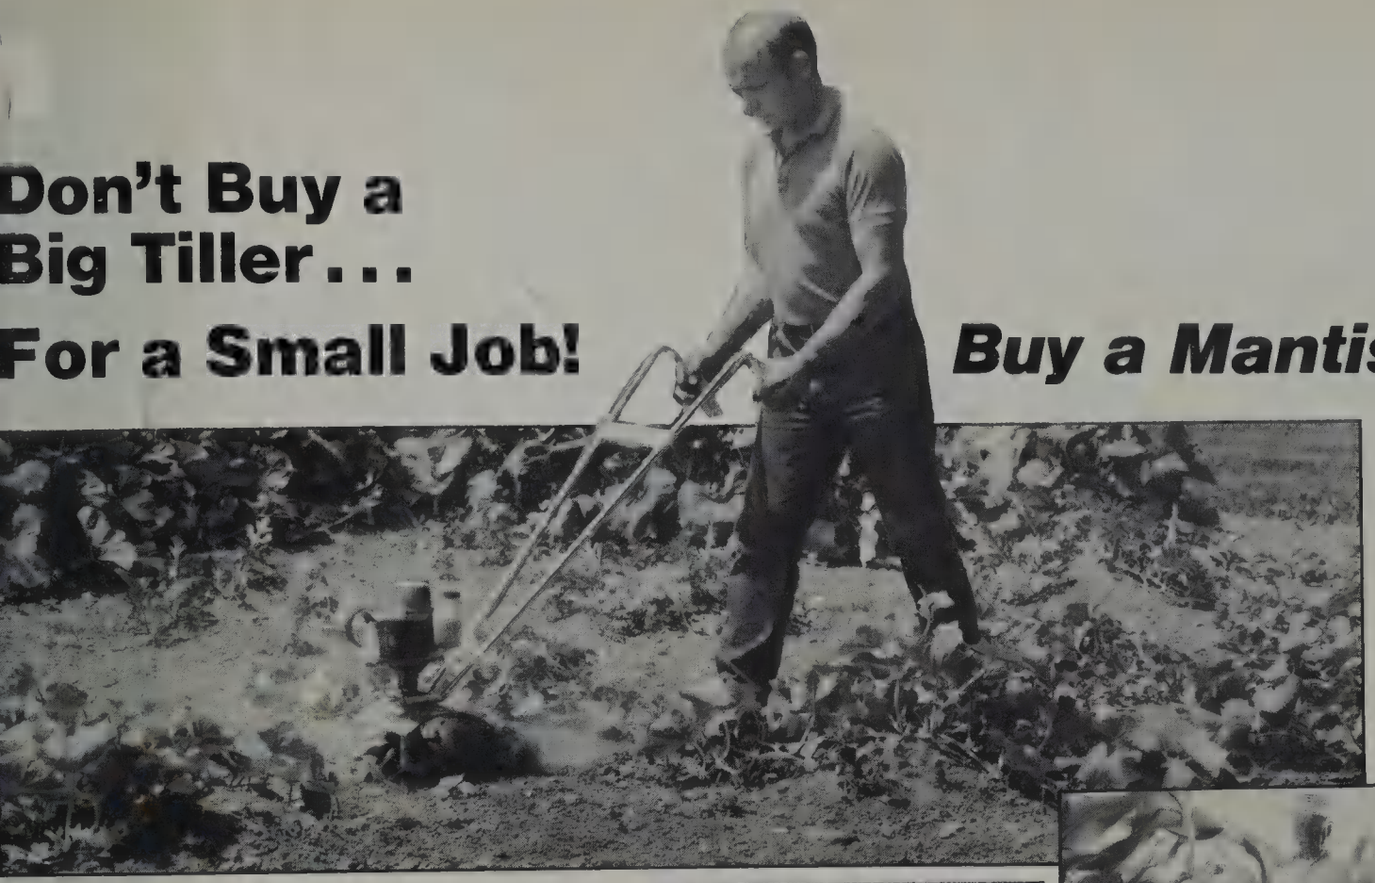
Various modern mechanisms in the ecology of infancy serve both to isolate the modern baby (the bedroom, crib, playpen, infant seat, walker, wind-up swing, and jump seat) and to increase its stimulation through physical objects (wallpaper, pictures, plants, and toys). We can get a better sense of how recent all these objects are in a child's life if we realize that objects in the parents' lives are also fairly recent. From the time of ancient Egypt until about A.D. 1500, it was not typical for even the homes of the wealthy to be furnished. People sat and slept on sacks of grain or mounds of straw. The wealthy had little besides a trestle table. In Moslem culture, a couch, a divan, or an ottoman was the symbol of the ruler and his court. When asked what they value most in their homes, modern parents more often than not indicate the furniture, and they often suggest that these objects are symbols of their personal accomplishment.

It was not, however, until this century that children began to inherit this state of affairs and to have privacy from the moment of birth. Furthermore, infants having their own bedrooms is largely a twentieth-century phenomenon, a final stage in the evolution of privacy since medieval days when everyone slept in the same room or those days when upper-class children slept with the servants. Some researchers believe that it was in the last

Don't Buy a Big Tiller...

For a Small Job!

Buy a Mantis!



Mantis cuts your weeding time by up to 90%! It gently cultivates the top 1"-3" of your soil without harming the delicate root systems of your flowers and vegetables.

Mantis quickly cuts neat borders to give that lovely landscaped look.

Mantis tills to 8" deep, cuts up sod, mixes in old vegetation, fluffs up soil.

Big tillers weigh almost 300 lbs. Mantis weighs just 20 lbs. (women and older gardeners love it)!

Simply turning a 300 lb. tiller in a backyard garden is a challenge. Mantis starts with a flick of the wrist... turns on a dime... and weeds between narrow rows and along fence lines.

The Mantis takes the work out of growing flowers and vegetables... so you can have more time to enjoy the results!

Most big tillers were designed to just till. Mantis was designed *from the beginning* for a variety of useful attachments. Tiller. Weeder. Furrower. Edger. Lawn Aerator. Lawn De-Thatcher. Hedge Trimmer.

Best of all, Mantis costs a *fraction* of what you'll pay for a big tiller.

3-Week In-Your-Garden Trial!

Mantis has a *Lifetime Warranty* on the tines (if they ever break, we'll replace them). A *Lifetime Replacement* agreement on the engine. And a *3-Week In-Your-Garden Trial* (if you don't like it, we'll take it back and give you a full refund).

LAST, LAST CHANCE To Buy Your Mantis At the LOWEST PRICE Of The Year!

...and beat the January price increase, too!...and receive a $41 Border Edger ...FREE!

EARLY ORDER BONUS

Mantis

Mantis Manufacturing Co.
1458 County Line Road, Dept. 807

1985 MMC

half of the eighteenth century that children in England first came to be regarded as consumers and agents for the ambition of middle-class parents. This was the time when books were first written specifically for children, using large print and simple language. It was also the time when toys became industrialized, when toy shows traveled around like circuses, and when toy shops were established in major cities. By 1800 some children were being dressed for the first time specifically in children's clothes. And most of the children of middle-class parents were being sent to elementary schools whose major function was to prepare the pupils for the new commercial (boys) and social (girls) opportunities of the Industrial Revolution. Even some working-class parents appear to have sought access to reading for their children and in some cases access to schools.

The modern child's bedroom is typically a place for both privacy and stimulation. Some experts think the rooms should be light and have fanciful wallpaper. One study has shown that parents tend to put animals on the walls of boys' bedrooms and floral decorations on those of girls. A dimmer switch, which allows modification of light at bedtime, or a night light saves the room from complete darkness.

Based on the view that babies enjoy novelty and like to explore their worlds visually, experts suggest that the crib be placed so that the child can look out a window, see colored pieces of glass or mobiles turning outside in a slight breeze, or perhaps see a bird feeder behind plants growing on the window sill. Small lamps hanging upside down may cast light spots on the ceiling. Wind chimes hanging near an air conditioner can make interesting sounds, and a radio going quietly in the background adds to the room's soothing effect. An industry has grown up around the development of the infant's bedroom and crib, but this probably has more to do with the culture's statement about itself than about its knowledge of the effects on the baby. Perhaps a baby in a more stimulating environment will become a livelier adult than otherwise, but that is by no means certain. More likely, the infant's bedroom and crib are a statement about the parents as well as an influence on their children. Parents decorate and furnish their homes to reflect those styles of architecture or painting they are particularly fond of or feel are fashionable. In this way they satisfy their interests and prove their worth to themselves and their friends. Similarly, infant bedrooms may demonstrate a parental concern for children and a belief in their early educability. They are the most recent reflection of parental ambition for the achievement of their young, which first became noticeable about 200 years ago.

Here again, we have the paradox that this frame of conventional niceness—animals or flowers on the walls and the moving mobiles over the cribs—is taking place in the one spot where, over the years, children can harbor whatever private wishes they choose, whatever fancies, whatever rebellions, whatever earthly concerns. In this solitary haven, embodying the parents' first vote for tranquillity, the child's future behavior, sane or monstrous, is incubated.

In time the child graduates from a crib to a playpen, which can be slept and played in, moved to the backyard, or put in the living room. It is decorated and filled with toys, and the baby may learn to walk by hanging on to the railing around the playpen's sides.

Experts recommend that parents put the playpen in a room other than the one they are working in because if the baby can see the parents, it will want to play with them rather than by itself. Left alone in another room, however, the baby will presumably play happily by itself for a long period of time. Still, parents are advised not to leave the child alone too long lest the playpen resemble a prison.

We justify the devices we use to isolate children by pointing out the relative danger of the modern home—with its electrical light sockets, dog dishes, cat litter, lamp cords, low coffee tables, small objects on the floor (pins, pennies, buttons, paper clips, screws, matches), television-set knobs, ashtrays, cigarette lighters, tablecloths, radiators, wastebaskets (containing razor blades and spoiled food), plastic bags, stairs, plants, and bottom cupboards filled with soaps, cleansers, and poisons. This array makes it feasible to argue that we isolate the baby for its own safety, not because isolation is an endemic characteristic of modern society; that isolating the baby shows our common sense, not our common character.

The physical seclusion of the child is also consistent with the use of toys to isolate the learning processes. This supports the thesis that an essential function of modern child rearing is to turn children into adults capable of functioning by themselves.

Although not many studies tell us just how children spend their time after infancy, at least one study, which focused on children in small nuclear families, found that in the second year of life children spend as much as 80 percent of their time by themselves. That involves exploring, accomplishing mastery, doing nothi much, eating, passing time, preparing f activity, and going to get things.

Children with siblings or peers in t neighborhood are, of course, more lik to convert play with toys into some form social play. Accordingly, we would expe that when they go to nursery school, whic places great emphasis on learning to c operate and to share, children would e gage in group play. But experiments sho that when toys are present, young childre are less likely to play with other childre and more likely to focus on the toys. Whe they are left with other children but wit out toys, they are more likely to play wit the other children than to play alone. Toy therefore seem to decrease the sociabilit of play. Nevertheless, new toys also, i time, make a contribution to new forms o social play. Earlier studies of playground also showed that if children had play ground apparatus, they played in a mor solitary way and with less aggression; bu if they had no playground apparatus the played together more often but with mor aggression.

Throughout the educational and thera peutic communities there is a perennia need to "socialize" children and to expec that those who do cooperate with other are in better developmental shape. Thi has led to the unnecessary contrasting o solitary and social play, whereas, in fact the healthy child is capable of both. True disturbed or maladjusted children ofte have enormous difficulties in social play but their problems should hardly be used to judge the functions of play among un disturbed children. Nor should these "spe cial" children be used to obscure the his torical drift toward isolation in the play o children with toys. We began with the par adox that parents use toys not only for the purpose of bonding but also, contradicto rily, for the purpose of shaping their chil dren into solitary self-sufficient individ uals; now, however, we find that once children are in school, their teachers and therapists try to resolve this paradox by emphasizing the cooperative purposes o play with toys. When parents implicitly say to their children, "We give you these toys in order to bond you to us, now go and play with them by yourselves," they are conveying to them an important message about civilization. That message may be subsequently undermined by therapists and educators who must deal with the less fortunate outcomes of our "civilized" loneliness.

Brian Sutton-Smith, is a professor of education and folklore at the University of Pennsylvania.

Olympus invents ESP for cameras.

Without ESP

With ESP

And suddenly the mind and the camera are one.

Because the new Olympus OM-PC has been blessed with ESP (Electro Selective Pattern metering).

So now you can skip that awkward stage known as beginner.

ESP is a mini-computer brain that intuitively knows what the eye is seeing, and automatically adjusts for light intensity and contrast. All the way from backlit to overlit.

And after you find the exact image you want in the viewfinder, Off-the-Film metering (OTF™) lifts it out of the air on to film the instant you see it. Just as you see it.

Since the OM-PC also features a choice of Program, Automatic, or Manual modes and prevents all common lighting mistakes, it advances the beginner automatically. While offering the option of over 300 compatible OM System accessories.

You'll see the true value of ESP when you pick up your first set of photos. And discover rich, natural colors instead of washed out or murky prints.

Of course, if you were born with ESP, this whole ad was unnecessary.

You already know the OM-PC will be your first 35mm SLR.

OLYMPUS

There is no longer a choice.

For more from the new Olympus OM-PC, visit Olympus Dealers in Woodbridge, N.J. 07095. In Canada, W. Carsen Co. Ltd., Toronto.

The fut of contr

Obviously this is a new Honda Accord. It's just not all that obvious. Or is it?

The front of the car is apparently low. Yet the engine is larger. Both have their advantages. Better aerodynamics so less power is needed. And more power when you need it.

The lower front offers less wind resistance. The streamlined shape contains retractable halogen headlamps. We've increased the size of the engine to two liters. The engine mounts have been redesigned to absorb vibrations.

Moving ahead to the rear, you'll notice the roofline is lower. Inside, however, you'll find more headroom. That's perfectly logical. Honda engineers choose to give room to people giving less room to the car.

The important part of the comfortab ride you enjoy inside is found outside the A unique suspension system that's never used on a front-wheel-drive car. Designer it a double wishbone and race cars have u it for years. We have used it on all four wheels like no other car.

Since the suspension is derived from many years of racing experience,

© 1985 American Honda Motor Co., Inc.

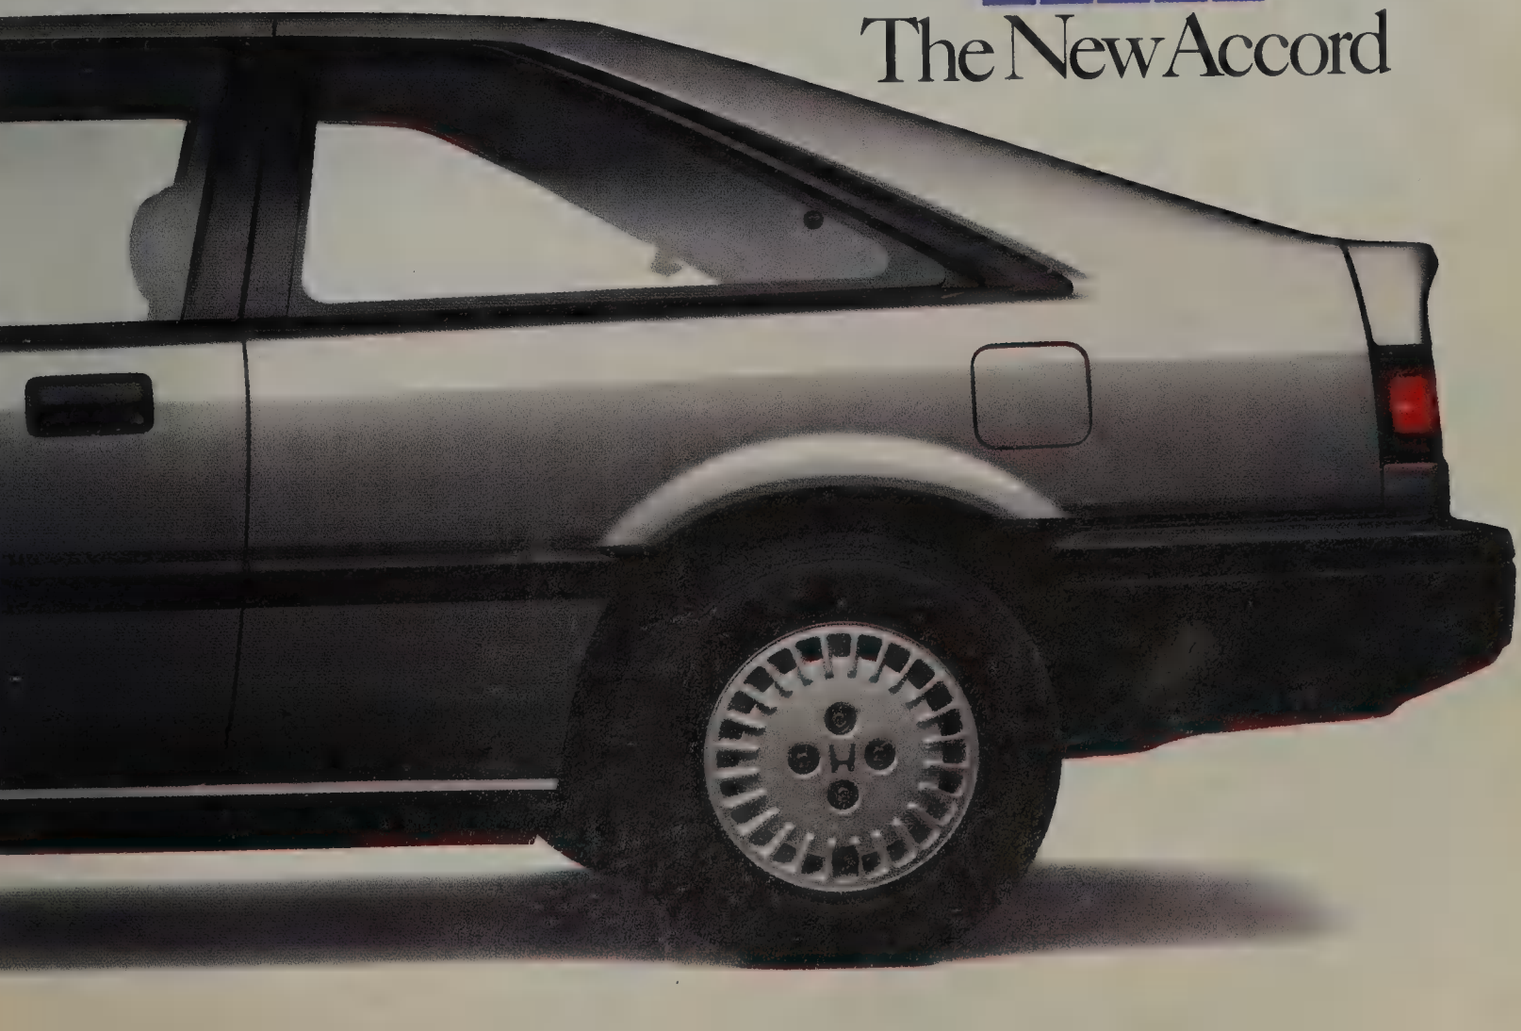
re is full dictions.

might deduce that the handling is an arating experience. You would be correct. The Accord DX Hatchback shown here es with rear seatbacks that split vertically ersatility. It has thirty-seven percent more o area. And there is a rigid cargo area cover. steering wheel adjusts. Panel switches work with a touch. And new front seats with adjustable headrests offer better support.

For your convenience, we have included a quartz digital clock. It will keep an accurate account of the good time you will have while driving the new Accord. Nothing contradictory about that.

HONDA

The New Accord



The Babylonians Saw That Comet, Too

Clay tablets show that the comet was noted nearly two millennia before Halley

by F. Richard Stephenson

While space scientists have been preparing for the forthcoming return of Halley's comet to the inner solar system after a lapse of seventy-six years, other researchers have been investigating ancient records of the comet's visits. The most remarkable achievement has been the discovery of observations from both 164 and 87 B.C. recorded on Babylonian clay tablets that are now in the British Museum in London. These are the earliest reliable accounts of the comet from any part of the world. Apart from their historical interest, the observations have enabled astronomers to test current theories regarding the comet's orbital motion.

Until about a century ago, very little was known about the great astronomical tradition of Babylon. However, the famous astronomer of Alexandria, Claudius Ptolemy—author of the *Almagest*—hinted at the true scale of observational astronomy as practiced in Babylon. Writing about a century after the time of Christ, he stated that he had access to astronomical observations from Babylon going back to the reign of King Nabonassar (747 B.C.).

Practically all our knowledge of Babylonian astronomy has come as the result of the discovery of ancient Babylonian texts. Somewhat surprisingly, very few of these texts were purposely excavated. Instead, they came to the notice of the scientific community in a haphazard way. During the eighteenth century, European travelers remarked on the pillaging of the vast ruins of what had been Babylon by gangs of laborers from nearby villages. This large-scale vandalism continued throughout much of the nineteenth century as building after building was demolished in order to remove their fine baked bricks for reuse in new construction. In the 1870s, however, large numbers of broken clay tablets bearing inscriptions began to reach antique dealers in Baghdad. These had evidently been dug up accidentally at the site of Babylon, and somehow their value as curios had been recognized. Almost all of the available material, numbering some 10,000 tablets, was bought by the British Museum through London dealers between 1876 and 1882. Then the supply ceased.

In the late nineteenth century, Assyriologists who were studying the Babylonian tablets in the British Museum, and could read the cuneiform in which they were written, recognized that a number of the tablets were concerned with astronomy. In the last two decades of the nineteenth century, researchers spent many years laboriously copying the Babylonian texts by hand; they also joined hundreds of broken tablet fragments. More than a thousand tablets devoted to astronomy were copied. Regrettably, most of these drawings were placed in the museum archives and remained forgotten until the early 1950s. We now know that several tablets referring to Comet Halley were among them.

After Edmond Halley in the early 1700s recognized the periodicity of the comet that now bears his name, historians and astronomers found records of its visits dating as early as 12 B.C. Before the European Renaissance, Chinese dynastic histories were the main source of observations; until recently, however, the investigation of possible sightings before 12 B.C. drew a virtual blank. The expected dates of the three previous appearances, based on modern calculations, are 240, 164, and 87 B.C. Ancient Greek and Roman writers mention several comets, but the dates are very vague. These difficulties led me to initiate a search of the Babylonian astronomical texts in the British Museum. Among ancient civilizations, only the Babylonians practiced stargazing as enthusiastically as the Chinese, but the study of their observations has been very limited.

The Babylonian texts were written in a cuneiform script on clay tablets. This type of writing, prevalent in the ancient Nea East, was produced by pressing a reed st lus into clay to form a series of triangula wedges. The clay was then sun-dried baked in ovens. Cuneiform writing wa first introduced by the Sumerians, and th earliest known documents date fro about 3100 B.C. The choice of materia was probably dictated by availabilit both clay and reeds are very common southern Iraq where the Sumerian civ lization flourished.

The texts have been classified into fou distinct groups: diaries, "goal year texts excerpts, and almanacs. Babylonia sightings of comets are noted only in th diaries, which are day-to-day summarie made by astronomers.

The diaries all originate from what known as the Late Babylonian period. Th earliest datable fragment comes from th year 652 B.C. and the next most recen from 568 B.C. (in the reign of King Nebu chadnezzar, during the exile of the Israe ites in Babylon). Most of the surviving dia ries come from between 380 and 60 B.C However, it seems likely that they orig nally covered the entire interval from 74 B.C. (as attested by Ptolemy) to at leas A.D. 75. In his *Almagest*, Ptolemy cite three Babylonian reports of eclipses fro years corresponding to 721 and 720 B.C Although there are no extant diaries fro this early period, tablets containin records of lunar eclipses, which the Bab ylonians excerpted from their own diarie go back at least as far as 702 B.C. Hardl any diaries are extant before about 38 B.C. or after about 60 B.C., but the reason not known.

From the diaries it is possible to recon struct a detailed picture of the kind of ob servations the Babylonian astronomer were making. A typical Late Babylonia diary contains astronomical observation for half a year. The Babylonians bega each month with the first visibility of th young crescent moon in the western sk

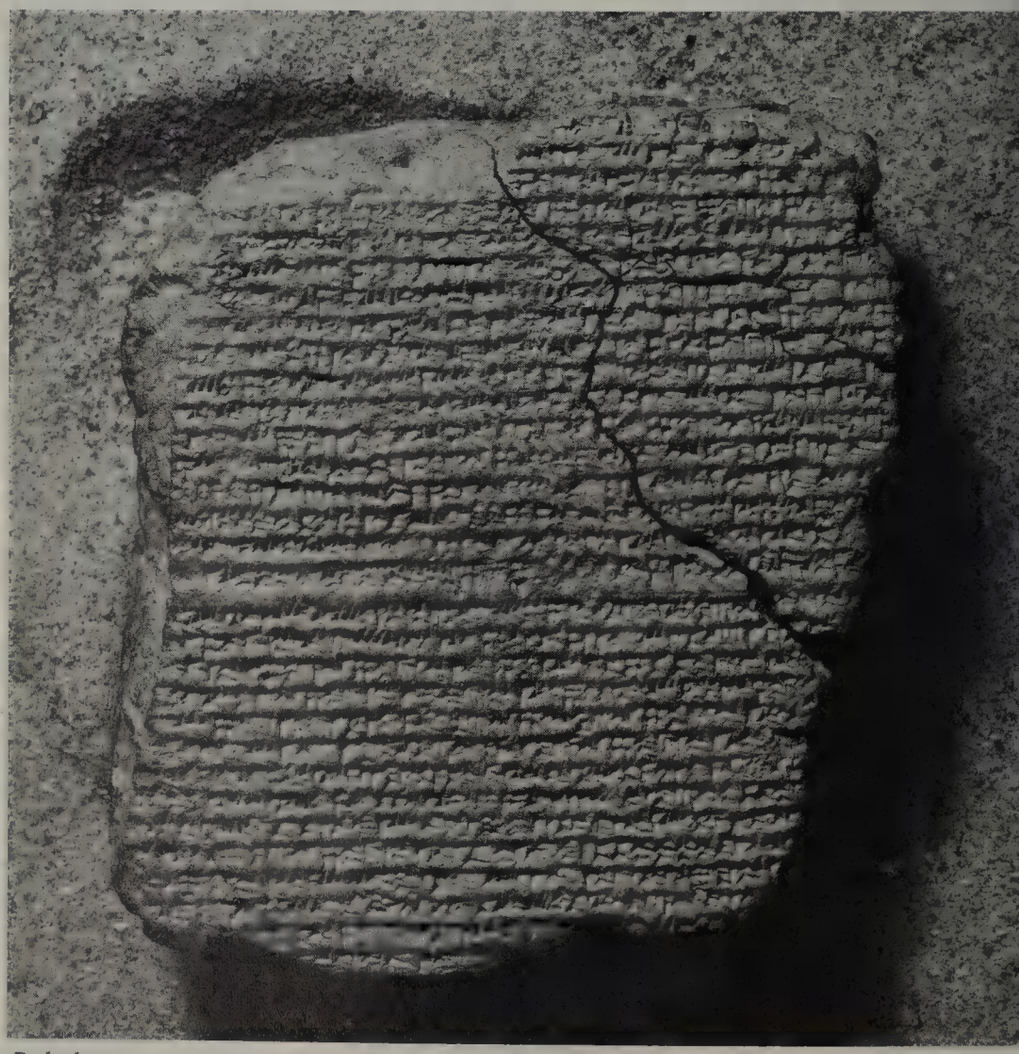
some twenty-four hours after new moon. Their day therefore began in the evening rather than at midnight. The search for the crescent moon closely resembles the observations made today in Islamic countries at the beginning and end of the month of Ramadan. The Babylonian month had either twenty-nine or thirty days, depending on whether or not the crescent moon was sighted at the close of the twenty-ninth day.

Night after night in each month, the conjunctions of the moon with the five bright planets (Mercury, Venus, Mars, Jupiter, and Saturn), as well as with thirty-one selected bright stars, were noted. These stars all lie in the zodiac, the apparent path of the sun, moon, and planets through the sky. The angular distance between the moon and each of these planets and stars was estimated in cubits and fingers, a cubit corresponding to an angle of about 2 or 2.5 degrees and a finger to one twenty-fourth of this amount. Other observations that involved the moon were of eclipses—both solar and lunar—and of the time interval between the rising and setting of the sun and moon at the beginning, middle, and end of the month. Eclipses were carefully observed, and both times and magnitudes were estimated. The most accurate account of a t tal eclipse from the ancient world is fro Babylon and was translated as follows:

Daytime of the 29th [of month Addaru II the year 175 of the Seleucid era], 24 *uš* [unit of time representing the interval for th sky to apparently turn through one degree and hence four minutes] after sunrise, a so lar eclipse began on the southwest sid . . . Venus, Mercury, and the normal star were visible. Jupiter and Mars, which were in their period of disappearance were vis ible in that eclipse . . . [the shadow] moved from southwest to northeast. [Time interva of] 35 *uš* for obscuration and clearing up.

The recorded date corresponds to 13 B.C. April 15, on which day modern cal culations indicate a total solar eclipse wa visible in Babylon. Both Jupiter and Mar were very close to the sun, as the record implies. The estimates of 96 minutes afte sunrise at the start and 140 minutes dura tion agree well with the calculated values The tablet text is badly broken, but thi account forms only a small part of the var ious kinds of astronomical information re corded on a small fragment of clay only about two square inches. Many careful ob servations of lunar eclipses have also sur vived. These data are of great value in cur rent studies of long-term changes in th



Babylonian stargazers noted Halley's comet in this 164 B.C. cuneiform diary.

QANTAS AIRWAYS

earth's rate of rotation due to tides and other causes.

For the planets, the diaries give the dates of first and last visibility, stationary points, and conjunctions with the above-mentioned thirty-one reference stars. Some of this information is calculated rather than observed. Other calculated information relates to the dates of the spring and autumn equinoxes and summer and winter solstices, as well as to the rising and setting of the bright star Sirius.

On each day we also find a brief weather report for both the daylight and nighttime hours. This details instances of clouds, rain, hail, thunder, lightning, rainbows, halos, and even wind direction. Curiously enough, fine weather is never mentioned; it can only be inferred from the lack of information to the contrary.

At the end of each month's day-to-day entries, there is a monthly summary. Based on calculation rather than observation, this summary lists the various signs of the zodiac in which the planets were situated. The Babylonians were the first to divide the zodiac belt into twelve signs, probably about 450 B.C. These names may be translated as: the Hired Man (corresponding to Aries), the Bull of Heaven (Taurus), the Great Twins (Gemini), the Crab (Cancer), the Lion (Leo), the Barley Stalk (Virgo), the Balance (Libra), the Scorpion (Scorpio), Pabilsag—a god—(Sagittarius), the Goatfish (Capricorn), the Giant (Aquarius), and the Tails (Pisces). It is evident that our modern Latin names, derived from the star catalog in Ptolemy's *Almagest,* are mostly direct translations of the Babylonian names, via the Greek of Ptolemy, with certain obvious exceptions.

The monthly summaries also provide information on the fluctuating amounts of six important commodities—barley, pepper, dates, cress, sesame, and wool—which could be bought for one shekel of silver. If prices changed during the course of a month, this was also indicated. Other details reported included changes in the level of the Euphrates River at Babylon—obviously with the risk of flooding in mind—and major local and national events. A particularly interesting piece of historical information is a notice of the death of Alexander the Great (who died at Babylon). The diaries allow us to date this event precisely as June 13 in 323 B.C. (Julian calendar).

Despite the irregular movements of comets, Babylonian records show that they were carefully observed. Descriptions of comets are found in the day-to-day entries in the diaries. That the objects termed *sallummu* by the Babylonians may be reliably identified as comets clear from the various observations. The indicate that the motions of *sallumm* were followed for many days, and not i frequently the direction in which the t (*mishu*) was pointing is specified. Furth support for a cometary interpretatio comes from the Chinese records. The can be little doubt that *sallummu* r ported in 157 and 138 B.C. are identic with comets that were independent sighted in China and described as "bush stars."

Judging from the preserved record damaged though they are, the Babyloni astronomers specifically noted the dat of first and last sighting of a comet and t constellations in which it appeared a disappeared. If a comet was temporari lost to view because of conjunction wi the sun, the dates of setting and risi were noted, together with the appropria constellations. The Babylonians do n seem to have intended to give a comple account of a comet's motion through t sky, as was the policy of Chinese astron mers in later centuries. The earliest me tion of a comet in the Babylonian diari was in 234 B.C., but after this date the are eight further known observatio down to 87 B.C. The years 234 and 87 B represent the earliest and latest datab records of comets in any cuneifor source. This obviously represents a rath narrow range of time. However, in probability comets attracted just as mu interest in Babylon during earlier cent ries even though the records are now lo

Two separate Babylonian tablets copies of the same diary but with slight different readings—contain overlappi descriptions of a comet in the autumn 164 B.C. The first of these accounts may translated as follows: "... the com which had previously been seen in the ea in the path of Anu in the area of Pleiad and Taurus, to the west... [brea ... and passed along in the path of Ea.

The other text, from a much more da aged fragment, begins almost where t previous record ends: "... in the path Ea in the area of Sagittarius, 1 cubit front of Jupiter and 3 cubits high towa the north."

As can be seen, the surviving portion the second text does not mention the wo *comet*. However, the use of the term Ea sufficient evidence. The Babyloni astronomers divided the sky into thr zones named after gods: Enlil, Anu, a Ea. Of these, Enlil was the northern sk Anu the equatorial region, and Ea t southern sky. These terms were nev used in describing the motion of plane but they were regularly used when com

Proudly Presenting - The New England Collectors Society's

First Frederic Remington Fine Art print "Dash for the Timber"

ACTUAL SIZE OF FRAMED PRINT: 29" x 43½"

A luxuriously framed Limited Edition of only 2,500 impressions.

- **Museum quality fine art print in vibrant full color completely true to the original.**
- **Exquisite hand-joined and hand-tooled solid hard wood frame with genuine burlap liner.**
- **Personalized Certificate of Registration.**

The world famous oil painting, *"Dash for the Timber,"* was Frederic Remington's first major commission as a fine artist. The breathtaking work dramatically portrays a band of frontiersmen racing from an overwhelming force of Apache warriors. Remington captured the intensity of the moment with brilliantly natural colors and with intricate, accurate detailing. The original now hangs in the Amon Carter Museum, Fort Worth, Texas. It is valued at $1,350,000.

And now, for the first time ever, the New England Collectors Society proudly offers you the opportunity to acquire a beautifully framed, Limited Edition fine art print of *"Dash for the Timber."* Each print in the strictly Limited Edition of only 2,500 impressions is a museum quality work which meets all professional criteria. Every print will be individually examined to assure that it completely matches Remington's extraordinary original.

"Dash for the Timber" is luxuriously framed in a custom designed, hand-joined and hand-tooled solid hard wood frame with a genuine burlap liner. The print is protected by shatter-resistant optically clear acrylic. It is a rewarding acquisition which will enrich your home and be treasured for generations.

Every subscriber will receive a distinctive, personalized Certificate of Registration attesting to the authenticity of the work and to its status as a Limited Edition.

NE **The New England Collectors Society**
237 Saw Mill Road, Box 414
West Haven, CT 06516

DT0001

Please accept my reservation for **"Dash for the Timber"** at $125.00 plus $3.00 for shipping and handling.* I understand that this is a Limited Edition of 2,500 museum quality framed prints. I need send no money now.

I prefer to pay as follows:

☐ Directly. Bill me for my deposit of $25.60* and, after my print is shipped, for the balance in four monthly installments of $25.60* each.

☐ By Credit Card. Charge my credit card in five equal payments of $25.60.*

were referred to (for example, in 210, 120, and 110 B.C.).

It is important to point out that neither of the tablets under discussion carries a date—not the year or the month. This information has been broken away and must be derived by calculations based on the lunar and planetary observations found in the same diaries. In each case, one side of the tablet contains records for parts of two consecutive lunar months, while the reverse side gives details for two further successive months. Both of the cometary accounts are found in the summary at the end of the first side. A date for each tablet of 164 B.C. had been deduced by calculating the planetary phenomena. It became essential for me to verify that date and to make sure that the *same* comet was referred to in both diaries; otherwise, the whole argument would have collapsed.

The key observation proved to be a lunar eclipse that was described on the reverse of both tablets. This was brought to my attention by the keeper in charge of the Babylonian texts at the British Museum, who—along with my student, Kevin Yau—contributed greatly to this investigation. Fortunately, a record of the same eclipse, duplicating most of the details, was also found on a goal-year text. This record gives the precise year of observation (148 of the Selucid era, corresponding to 164–3 B.C.). Other data in the two diaries, such as the constellations in which the planets were found and conjunctions of both the moon and Venus with stars, enabled me to derive a unique date for both cometary records: the lunar month beginning on October 21 (Julian calendar) in 164 B.C. Equally important, several of the lunar and planetary observations in each diary were identical, proving that the tablets are essentially copies of one another. Hence it is evident that the two references to the comet are part of one and the same description.

The composite record of the comet of 164 B.C. agrees extremely well with the calculated motion based on orbital theories. According to those calculations, Halley's comet should have been first sighted between the Pleiades and Aldebaran (the principal star of Taurus) toward the end of September, and about a month later it should have passed about seven degrees (roughly three cubits) to the north of Jupiter, then in Sagittarius. The comet would then be approaching conjunction with the sun and would soon be lost in the evening twilight. The agreement with observation is thus excellent, and there can be no doubt regarding the identity of the comet as Halley's. The rather precise location, "1 cubit in front of [that is, to the west of] and 3 cubits high toward the north" ma well represent the position at last visibilit This would fit in with the characteristi style of Babylonian cometary record which are mainly concerned with first an last sightings.

For 87 B.C., we found only a single brie record of a comet on a small fragment of tablet. The text may be translated as fo lows: "... on the 13th, the interval be tween moonrise and sunset was measure as 8 *uš*. In the first part of the night comet ... [break] ... which in month I day beyond day one cubit ... [break ... between north and west its tail 4 cubi ...."

Once again, neither year nor month preserved. However, there are severa valuable lunar and planetary observa tions, including an eclipse. A starting ep och is provided by the mention of Selet cia, a city that was not founded until 27 B.C. Investigation of the astronomical dat makes possible the derivation of a uniqu date for the diary entry—August 24 in 8 B.C. The lunar month can be readily show to be the fifth of the appropriate year fo the scheme of intercalation adopted b the Babylonians to keep their calendar i step with the seasons. The survivin record of the comet seems to relate almo entirely to the previous month IV (July 1 to August 11), but this is the customar pattern. For much of month IV, Halley comet should have been moving at ap proximately "1 cubit" daily, while its ta would have pointed roughly northwest. B August 24, the day of the diary entry, th comet would have been difficult to discer in the evening twilight. Despite the loss much valuable information, there enough evidence here to identify Com Halley with confidence.

All three Babylonian accounts of Ha ley's comet are of considerable historic interest, since they allow us to extend th record of the comet by two additional r turns—87 B.C. and 164 B.C. These sam reports are also valuable in the study the comet's orbital motion. Despite the apparent crudity, the observations enab us to date the perihelion passage (close approach to the sun) in ancient times mo accurately than modern computations w permit. It is my hope that the missing Ba ylonian observations from even earlier vi its of this most famous of all comets ma yet come to light.

F. Richard Stephenson is an astronom and senior research fellow in the Depar ment of Physics at the University of Du ham in England. His research is centere on historical astronomical records th have value for present-day astronomy.

Sail in it, go to tea in it, shop in it, ski in it—wind or rain won't faze our classic Squall Jacket.

The new Lands' End Squall Jacket takes its name, of course, from its ability to weather the squalls that our sailing friends encounter off shore. But it's so well-tailored and correct it makes you look good—man or woman alike—in the mall or at the market or at the movies or after. That's versatile plus, right?

Beyond that, you could pay up to $96 or so for a jacket like this in a sporting goods store specializing in high tech outerwear. But in our traditional pattern-breaking way, Lands' End has found ways once more to marry top quality with a palatable price. We offer all this handsome lightweight warmth and comfort for only $69.00. And in youth sizes, just $57.00.

A classic, inside and out. The outer shell of this waist-length jacket is a tough tri-blend of cotton, nylon and polyester—the blend we've found most certain proof against both wind and rain. The inner material is a soft, lightweight bunting—brushed on both sides to maintain loft. (Bunting is as close as mortal man can come to imitating wool fleece—and a credible effort it is, too!)

And note this: the full-length inside storm flap of our jacket is tucked *beneath* the smooth-running zipper . . . to keep the wind from whistling between the teeth of the zipper as it can on ordinary jackets. The Squall has fully-lined sleeves, zippered hand-warmer cargo pockets, a high collar that protects neck and chin, even a zippered inside pocket for your keys and I.D. All this, and it's machine washable.

A jacket for all seasons. Really. The Lands' End Squall Jacket is here now, just in time for Spring and Summer. But it's a jacket you'll turn to time and again for Fall and Winter. Its style flatters both men and women. And the color choice is inspired. Consider: mauve (women only), royal, jade, yellow, and red—all with Navy trim. Like everything we make and market it's GUARANTEED. PERIOD.

A visionary tip: order one for your young son or daughter and see how quickly it becomes for them the "in" thing to wear. Leave it to kids to know what's good.

As for what else is new in Dodgeville, send for our free catalog via the coupon below. Or phone us at our toll-free number 800-356-4444, day or night.

Treasures in a Taxonomic Wastebasket

As scientists restudy the Burgess Shale fossils, life in the Cambrian gets curiouser and curiouser

by Stephen Jay Gould

I shall begin by playing a little John Fowles (of *The French Lieutenant's Woman*) in reverse—and why not, since the hero of that novel may be literature's most famous paleontologist. Fowles's book has two endings; this essay has two introductions.

INTRODUCTION 1: In the *Canadian Alpine Journal* for 1908, Charles Doolittle Walcott, paleontologist and secretary (their name for boss) of the Smithsonian Institution, described the appropriate technology for collecting from the great *Ogygopsis* fossil bed of British Columbia:

> The best way to make a collection from the "fossil bed" is to ride up the trail on a pony to about 2,000 feet above the railroad, collect specimens, securely wrap them in paper, place them in a bag, tie the bag to the saddle, and lead the pony down the mountain. A fine lot can be secured in a long day's trip, 6:00 A.M. to 6:00 P.M.

Walcott's ineluctable choice of horsepower led directly to his accidental discovery, the following year, of the most famous and important of all fossil localities (see following article, page 34). I have read two versions of the story. Both agree that the great moment occurred on the final day of the 1909 field season, as Walcott and party led their horses down the slope toward the railroad for the last time. Snow and night had both begun to fall. In one version (the more romantic), Mrs. Walcott's horse slides going downslope and turns up the celebrated slab—the one last rock that Walcott must then examine. In the other version, the slab lies in the middle of the path, blocking their way—and Walcott must dismount to push it aside. In either case, he looks as he pushes (the trademark of any good geologist), and he finds the rarest and most precious of all paleontological gifts—exquisite preservation with soft parts intact. (Any recovery of soft parts is sufficient cause for hosannas in itself, but this fauna inhabited the oldest rocks of our fossil record as understood in Walcott's day—the Cambrian period.)

Walcott bided his time anxiously, returned the next summer, and traced the errant block to its source—a shale lentil above the *Ogygopsis* bed and seven to eight feet thick. He excavated the entire lentil—now called the Burgess Shale—during the next two seasons, as a family affair before the days of "big" science. Walcott wrote:

> Accompanied by my two sons, Sidney and Stuart . . . we finally located the fossil-bearing band. After that, for 30 days we quarried the shale, slid it down the mountain side in blocks to a trail, and transported it to camp on pack horses, where, assisted by Mrs. Walcott, the shale was split, trimmed and packed, and then taken down to the railway station at Field, 3,000 feet below.

INTRODUCTION 2: My office occupies the oldest wing of Harvard's Museum of Comparative Zoology. When we washed the walls in preparation for the first paint job in anyone's memory, we uncovered, in swirling Victorian calligraphy, a taxonomic dictionary of the 1870s. I discovered that I inhabit the former focus and entering exhibit of Louis Agassiz's original museum. (I was doubly delighted because we then didn't have to cover the walls in sparkling white and disrupt my life as only painters can.) The headline to each section reads: "Synopsis of the Animal Kingdom," and the order progresses, by the conventional chain of being, from "Sponges and Protozoa" just under my desk all the way to "Mammals" on the wall. Evidently, this room housed the e ome and key to the entire collection— short take on God's arrangement Agassiz's view) of organisms.

I chuckled when I read the connect link between "lower" (sponges and cora and "higher" (lobsters and clams) inve brates. The label read, simply, "Verme or worms. I laughed because I recogni this name as the old cop-out or garb bag for a major problem of invertebr taxonomy. Some phyla are large, distin and well bounded; we can usually plac coral, a sponge, a bug, or a snail with difficulty. But invertebrate life include wide and frustratingly diverse array soft-bodied, elongated, bilaterally sy metrical animals with sensory organs a mouths up front. We know that, coll tively, they represent a genealogi hodgepodge as wide as invertebrate life self.

Animals sharing this basic architect may have no closer affinity than a bee and a squid. We now have many names them—chaetognaths, gnathostomuli priapulids, kinorhynchs, and so forth but we still don't know their relationsh Our predecessors, following a tradit dating to Linnaeus himself, tended dump them all together into an incho group called Vermes—and I had disc ered an example of this ancient pract on my own wall. The older taxonom knew that Vermes housed an array of ferent creatures, united by an anatomi plan so basic and generalized that it mi evolve again and again in unrelated for They knew, in short, that Vermes was unnatural assemblage—a taxonor wastebasket for the invertebrates that one understood.

The conjunction of these disparate introductions is quite simple. Walcott found an array of unique, soft-bodied animals in the Burgess Shale—bilaterally symmetrical creatures of anatomical designs found nowhere else among living or fossil organisms. This discovery defines the greatest interest, and transcendant importance, of the Burgess for our understanding of evolution and the history of life. But Walcott never appreciated what he had found. He followed the usual road and buried his new world in taxonomic convention. He managed to shoehorn every Burgess animal into a modern taxonomic group, and he placed all the real oddballs among the worms. This fateful decision delayed a proper appreciation of the Burgess Shale for more than fifty years. Most well-informed scientists still don't know what treasures the Burgess really contains. We are only now beginning to see properly and to ponder the cascading implications—an exercise so broad that it must occupy this and my next two columns and still only scratch the surface.

The unusual setting of the Burgess Shale explains why it has preserved the remains of soft-bodied creatures. A massive algal reef, represented today as dolomites of the Cathedral Formation, towered above deep and quiet bottom waters during Middle Cambrian times near the edge of a sea that became part of British Columbia. These deep and stagnant waters were depleted of oxygen (and therefore devoid of complex life), presumably as a result of poor or nonexistent circulation. But mud banks accumulated at the edge of the stagnant basin, adjoining the projecting reef. Here, in well-oxygenated, shallower waters, the varied fauna of the Burgess thrived. Every once in a while, perhaps as a consequence of small earthquakes or other tectonic movements, perhaps simply as a result of sediments accumulating beyond their own point of stability, these muddy banks foundered and slid into the adjoining stagnant basin—a so-called turbidity flow in geological parlance. Suddenly buried in a quiet and stagnant basin devoid of organisms that could eat their remains or even cause them to decay, the soft-bodied creatures of the Burgess mud bank entered a tomb that has endured for some 530 million years.

From the time he discovered the Burgess Shale until after his death in 1927 (in several posthumous papers), Walcott described most of the Burgess animals in a long series of articles for the *Smithsonian Miscellaneous Collections*. This set of papers represents the most anomalous match I know between attention and significance in science—for Walcott's descriptions are the merest thumbnail sketches (he did have other things to do as boss of the world's largest museum), while the Burgess animals are the world's most important fossils. (Our inordinate interest in Lucy and her ilk is only parochial concern, however appropriate, for one little twig of the evolutionary tree—while the Burgess animals represent all we have of several main trunks.)

The reasons for this curious lack of attention are many and varied (including the sociology of territory among paleontologists), but one intellectual factor stands out. Walcott simply didn't recognize what he had—and others, therefore, never sensed the richness. For him, the Burgess fossils were beautiful and unusual in their preservation, but not unique in their biology. Walcott simply placed them in modern groups. I could find not the slightest flicker of a doubt, not a hint of any possible alternative, throughout his papers. (I shall devote next month's column to the reasons for Walcott's decision and to the interesting fallacy underlying it.) In his greatest single burial of uniqueness within conventional taxonomy, Walcott put almost every bizarre Burgess organism into the traditional wastebucket, Vermes (*Smithsonian Miscellaneous Collections*, vol. 57, 1911, p. 109), in particular into the phylum Annelida (segmented worms, including earthworms and leeches).

The last decade has marked a great leap forward in study and understanding of the Burgess Shale. Walcott thought he had

larly the trilobites, are comfortably placed within well-known groups. But many, including the most complex and exquisite of Burgess organisms, are acutely disconcerting for anyone with a passion for tidy order: arthropods they clearly are, but like no others. They bear the distinctive bits and pieces, but in arrangements, numbers, and proportions unknown elsewhere. Paleontologists responded to this assault upon taxonomic comfort by the usual strategy: they erected yet another wastebasket and called them all Trilobitoidea (or trilobite-like creatures). But this name hid a diversity of disparate animals, just as Vermes had provided a verbal rug to cover wider discomfort.

If many Burgess organisms represent unique designs within established phyla, then we need only crank up the argument one step to dismantle Walcott's Vermes (for as Trilobitoidea hid the oddballs among arthropods, Vermes sheltered the oddballs among *animals*). Simon Conway Morris has pioneered this revolutionary interpretation. ("Revolutionary" may be the most overused word in science today, and I shudder to write it—but how appropriate in this case.) Simon estimates th
about a dozen Burgess genera cannot
placed into any modern phylum, and th
their aggregate anatomical diversity m
span the entire range of invertebrate d
sign.

Consider just one picture from Simo
review of the Burgess Shale fauna (
Conway Morris, *Annual Reviews of Ec*
ogy and Systematics, vol. 10, 1979,
327). Simon drew this figure to illustra
representative Burgess organisms, not
focus upon oddballs (it doesn't even
clude *Hallucigenia,* weirdest creature
all—see my column of July 1983). E
Marrella splendens, most common of
Burgess animals and obviously an arth
pod, but of a kind unto itself. C is
priapulid worm, a dominant group with
the Burgess, but a minor component
most invertebrate faunas today. The oth
three creatures are mysteries. *Amisk*

could focus this column directly upon s diversity, and produce a kind of bestiy, but such is not my way. I prefer clear l elegant cases, for castles are only so rable as their building stones. I have nted to write about the Burgess faunas years, but was only inspired by a parular study, Simon Conway Morris's nograph, hot off the press, of *Wiwaxia rugata,* yet another Burgess oddball Conway Morris, *The Middle Camian metazoan* Wiwaxia corrugata *(Matw) from the Burgess Shale and* ygopsis *Shale, British Columbia, Cana, Philosophical Transactions of the yal Society of London,* vol. 307, 1985, 507–586). Which leads to . . .

TRODUCTION 3: The science that ches our newspapers and magazines is mall and biased subset of the interest- work done by professionals. Talks at blic meetings and short articles in such neral journals as *Science* and *Nature* ke their easy way into public consciousss, but science writers rarely read the sic repositories of technical informan—the specialty journals and, particuly in my field of systematics, taxonomic nographs. I regret this system of closed d open channels because so much of the st instructive and exciting science in profession appears, traditionally and propriately, in these long descriptive mpendia that never see general light, ough they move our profession forward proper attention among small groups of perts.

The *Philosophical Transactions of the yal Society of London* (or *Phil Trans* the cognoscenti) is the oldest, contin- lly published, scientific journal in Eng- h. It printed the works of Newton in the venteenth century, and it continues to blish the basic data of science today. y colleague Simon Conway Morris has t presented, in this venerable journal, a -page (and 173-picture) monograph on inch-long invertebrate that lived 530 llion years ago—the very sort of docuent that science writers rarely see or diss, and a great pity in this case, for Sion's monograph has something portant to tell us all. We must somehow rn to respect the basic data of science, t only its flashy theories.

The body of *Wiwaxia corrugata* is a ttened, elongated oval, averaging enty-six millimeters (about an inch) in gth and ten millimeters in maximum height (excluding spines); the champ that didn't get away measures fifty-two millimeters in length. The basic form of the body is simple: no segments, no demarcation of head, trunk, or tail, no sensory organs—basically an uninterrupted oval in outline. (We can make a reasonable inference about fronts and backs and tops and bottoms because a food-gathering apparatus occupied the front end of an apparently straight gut; one surface, presumably the bottom, was naked, while the opposite side carried two projecting rows of spines.)

Upon this uninspiring basic body, *Wiwaxia corrugata* sports a distinctive feature that places it among the most conspicuous and intricate of Burgess Shale organisms: the body (except for the naked belly) is covered with sclerites (projecting blades of stiff, but nonmineralized, tissue), each attached into an indentation of the body surface by a single rounded or pointed root.

The sclerites of *Wiwaxia* grew in two different styles: flattened *scales* (ornamented with parallel ridges) cover most of the body, while two rows of *spines* emerge from the top surface, one on each side of the central axis (see figure of Simon's re-

NordicTrack

Cross Country Skiing Exerciser

Builds Cardiovascular Fitness More Effectively Than Other Exercisers

"NordicTrack provides the same superior fitness building benefits as real X-C skiing."

Bill Koch
8 time Nat'l X-C Ski Champion
Olympic Silver Medalist
World Cup Winner

©PSI 1985

NordicTrack duplicates the smooth, rhythmic motion of cross country skiing, recognized by health authorities as the most effective fitness building exercise available.

Jarless Action is Better Than Running

Does not cause joint or back problems. More complete. Resistance on arm motion provides a superior upper body exercise.

More Complete Than Exercise Bikes

Adds important upper body exercise and provides more uniform leg muscle usage. Higher pulse rates, necessary for building fitness, seem easier because more muscles share the exercise.

More Effective and Safer Than Rowing Machines

Safer because no dangerous back strain loads imposed. Scientific tests prove NordicTrack's skiing motion is superior to rowing for building fitness.

Burns off 200 - 600 Calories per 20 Minute Workout

For effective weight control.

Exclusive Flywheel Action

Provides unmatched smoothness and continuity from stride to stride. Motion and resistances are same as real skiing.

Folds Compactly

Requires only 15" x 17" floor space.

The long and short of zoom lenses.

Nikon fixed focal length lenses have long been the undisputed choice of professional photographers.

What many people don't realize, however, is that Nikon also makes the world's largest selection of zoom lenses. Lenses so superior that pros, who traditionally haven't used zoom lenses, willingly use these.

That's because the same technology and care that goes into building Nikon fixed focal length lenses goes into building Nikon zooms. We offer special features like Nikon Integrated Coating and Nikon Extra-low Dispersion glass. Plus, unlike many lens companies, we make our own glass. So every Nikon zoom produces sharp, high-contrast images, and accurate color transmission.

So if you're looking for a zoom lens, visit your nearest Nikon dealer.

It's where you'll not only find the most. But what many consider the best.

Nikon
We take the world's greatest pictures.

Now Nikon lenses look even better.

NIKON LENS REBATE	
Lens	Rebate
24mm f2.8 Nikkor	$25
28mm f2.8 Nikkor	$20
55mm f2.8 Micro Nikkor	$20
85mm f2 Nikkor	$25
105mm f2.5 Nikkor	$25
35-105mm f3.5-4.5 Nikkor	$15
35-135mm f3.5-4.5 Nikkor	$20
70-210mm f4 Series E	$40
80-200mm f4 Nikkor	$25

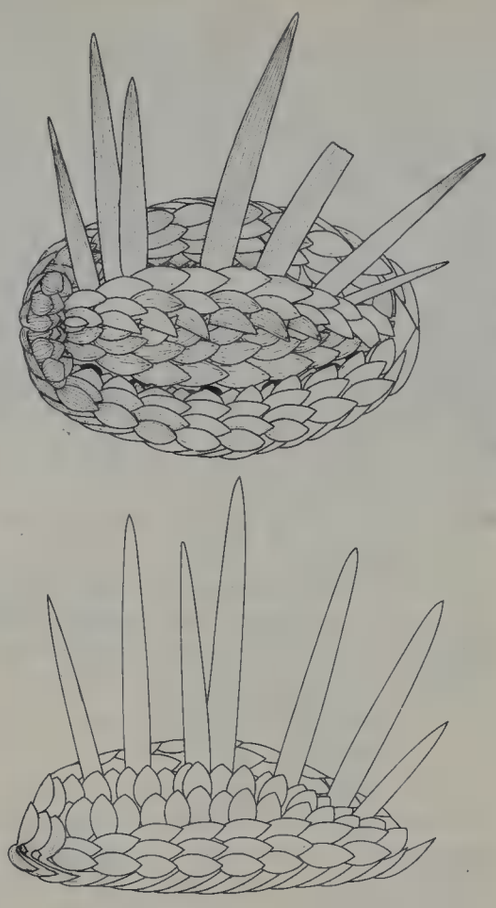
We're offering rebates on ne of our most popular nses, from wide angles to elephotos and zooms. So you an get the lens you really ant, instead of settling for a rand you don't.

Just make sure the lens ou buy comes with an offi- al Nikon Inc. Warranty pplication, and get a rebate pplication from your dealer. When you send in the applica- ons, we'll send you a check -along with your Nikon USA lub membership.

Of course, a rebate offer one may not convince you o buy a lens. But it might elp you to buy the right one.

Nikon
We take the world's greatest pictures.®

ffer applies only to eligible Nikon Inc. USA products. For rther information, write Department N1, Nikon Inc., 23 Stewart Ave., Garden City, NY 11530. Offer good from eptember 1 to December 31, 1985. © Nikon Inc. 1985.



Simon Conway Morris's reconstruction of *Wiwaxia corrugata*. From *Philosophical Transactions of the Royal Society of London*, vol. 307, 1985, p. 560

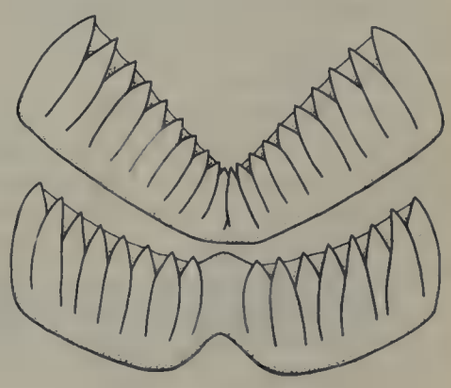
construction). The sclerites grew in an ordered arrangement—a field of overlapping blades on top, arrayed as six parallel rows (top view of the figure) and two regions on each side (bottom view), two upper rows with sclerites pointing upward and two lower rows with sclerites pointing backward. We find, however, no sign of regular segmentation within these ordered fields.

Simon could see little of *Wiwaxia*'s internal anatomy—some hints of a straight gut perhaps, but not much else. One feature, however, may be important in judging the biological relationships of *Wiwaxia*. About five millimeters from the anterior end, Simon found two arcuate bars, each carrying a row of simple, conical teeth directed toward the rear. The front bar bears a notch at its center, marking a toothless area between side regions bearing seven to eight teeth (see figure); the rear bar has a straight margin with teeth all along the other edge. These structures were probably attached to the bottom of the gut. By this evidence of form and position, their interpretation as feeding devices seems well founded.

Simon could make other inferences beyond adult anatomy. The absent or relatively small spines of small specimens indicate change of form with growth. Two juxtaposed specimens seem to represent an act of molting by one individual, not two animals accidentally pushed together in the turbidity slide that buried the Burgess fauna. The smaller specimen is shrunken and elongate, as if the larger body had just crawled out, leaving its old surface behind as "a vacated husk." Small brachiopods, occasionally attached to a sclerite, indicate that *Wiwaxia* crawled along the top of the sediment; it did not burrow within (where the brachiopod could not have survived). Patterns of breakage in several spines may point both to the activity of predators (presumably among the arthropods) and the possibility of escape. The feeding bars seem to indicate a life spent scraping algae or gathering detritus on the sea floor. In short, *Wiwaxia* was probably an herbivore or omnivore, living on small items of food collected from the sediment surface as it crawled along the sea floor. We can learn quite a lot from a few flattened films preserved on shale beds—and the neglected literature of taxonomic monographs houses this information in all its fascinating detail. (The stringent space limitations of most professional journals do not permit the leisurely pace and complex development that such presentations require.)

Simon may have reconstructed the anatomy of *Wiwaxia* and inferred its mode of life with signal success, but we are left with the biggest of all mysteries. What is it, genealogically speaking?

Walcott christened the genus *Wiwaxia* in 1911 (after the local name for a neighboring group of small mountain peaks). He placed it among the worms, with all other Burgess mysteries—in this case into the class Polychaeta (the dominant group of segmented marine worms). An ironic story surrounds an earlier, and first, discovery of *Wiwaxia*. In 1899, G. F. Matthew described a single spine of *Wiwaxia* from the *Ogygopsis* bed below Walcott's Burgess quarry (then undiscovered). (Isolated sclerites of *Wiwaxia* are stiff enough to resist decay and be preserved in ordinary fossil beds, but complete specimens are known only from the Burgess Shale



From the Royal Society's *Transactions*, p. 558

Smithsonian Archi

Fossil collecting in 1913 at the Burgess Shale on the west slope of Mount Wapta, British Columbia

lentils.) Matthew described this single spine as a hyolithid of the genus *Orthotheca*. Hyolithids are now regarded as yet another oddball group of uncertain affinity, probably meriting a separate phylum in their own right. Did Matthew, then, begin *Wiwaxia*'s history with a proper note of genealogical uniqueness, though in the wrong scale? Scarcely. Matthew, applying the conventional shoehorn of his day, placed hyolithids among the annelids—so *Wiwaxia* resided in Vermes from the start.

As Simon argues convincingly, *Wiwaxia* won't work as an annelid (segmented) worm. Beyond the meaningless externality of its oval shape and bilateral symmetry, nothing about *Wiwaxia* says annelid or any kind of recognized worm. Neither its body nor its sclerites show the slightest sign of segmentation (a defining character of Annelida); it lacks setae (the movable bristles of most annelids), and its sclerites are not built like plates and spines that adorn some annelids.

Might another modern phylum be a possible candidate? The two feeding bars do recall a defining character of mollusks—the radula (also a bar of teeth lying at the anterior end of the gut). But little else suggests affinities with clams, snails, and their ilk. *Wiwaxia*'s body form and mode of life seem most unmolluscan (though a little-known group, the Aplacophora, does include unshelled, basically wormlike creatures with radulae). But mollusks do not grow by molting, and none has a structure anything like the defining sclerites of *Wiwaxia*.

Simon concludes that *Wiwaxia* and its allies (the isolated sclerites found in other Cambrian deposits) deserve a phylum of their own, perhaps closer to mollusks than to other living groups, but still distinct. Perhaps, he argues, several related body plans of a "supermolluscan" lineage vied during these early days of life's history, most dying in the low diversity of youth (wiwaxiids and hyoliths, for example); one—the true mollusks—surviving and radiating. As an alternative of even more mystery, the tenuous link to mollusks may be illusory and based on independent evolution of a similar feeding organ—and *Wiwaxia* may bear no recognizable relationship, however vague and distant, to any modern group.

Thus, the Burgess story gets curiouser and curiouser as the restudy of Walcott's specimens proceeds apace. The new invertebrate phyla from this single locality may eventually reach half the number of those inhabiting our entire earth today (about twenty to thirty by various counts).

I must emphasize—to define the depth of this intellectual puzzle—that the Burgess is no ordinary soft-bodied fossil fauna. Such faunas are rare indeed, but several exist (including the famous lithographic limestone of Solnhofen, home of *Archaeopteryx,* the first bird), and none contains anything like the diversity of the Burgess Shale. In particular, no other soft-bodied fauna collection includes more than one or two unplaceable oddballs, while the Burgess may house more than a dozen. Why this difference?

The Burgess (fortunately for us) occupies a crucial time in life's history. It represents our only "window" upon the first great radiation of complex life on earth. All but one or two modern phyla originated in a burst of evolutionary activity associated with the so-called Cambrian explosion some 570 million years ago. The Burgess provides our only peek at the soft-bodied forms of this first flowering. All other soft-bodied fossil assemblages are much younger; they represent faunas well past the initial burst and sorting out of Cambrian times.

I wrote a previous column on this aspect of the Burgess mystery (July 1983). I argued that a pattern of "early experimentation and later standardization" underlies this initial burst and later restriction of taxonomic mysteries—the Burgess Shale should abound with phylum-level body plans of low diversity and limited range. the Cambrian explosion represented t first flowering of modern multicellul life, then we might anticipate an init phase of vigorous experimentation with permutations of possible designs and later restriction and sorting out of best lutions (or, perhaps, merely of lucky sur vors among varied opportunities). I d cussed possible explanations for t pattern, primarily contrasting the hypot eses of improvement in anatomical en neering versus simple good fortune—a will not treat this fascinating topic any fu ther here. I want, instead, to close by d cussing a different issue, previous avoided: *how* could early multicellular l generate so many radically different bo plans so fast? Life is not producing t kind of diversity today.

This dilemma has two potential kinds solutions. The first, traditional for mo than a century and only recently under rious challenge, holds that no proble really exists—that the appearance of u usually rapid evolution at the Cambri explosion is an artifact of our imperfe fossil record. The artifact theory comes several versions (I will discuss Walcott's next month's column). The most plausil scenario holds that Precambrian multic lular life had a long history of gradu development, leading in continuity towa the products of the Cambrian explosi but that Precambrian faunas were all so bodied and, therefore, not preserved. T Cambrian explosion only marks the evo tion of hard parts (perhaps reflecting change in oceanic chemistry or the evo tion of predators that might encour such a defensive response), not the orig of anatomical complexity.

If the artifact theory is correct, then f get the rest of this essay (but don't be a noyed; I've given you a fair amount good stuff already). But several events the past two decades have seriously wea ened this venerable theory, perhaps tally. Our knowledge of Precambrian a

Found!

Some of Man's First Silver Coins

These authenticated silver coins bear the famous "archer king" design — celebrating the martial glory of the Persian Empire.

Shown 2× Actual size

Struck up to 2,500 years ago in Ancient Greece, these genuine artifacts were among the first silver coins in all of history!

October, 1985. Montpelier, Vermont. **International Coins & Currency, Inc., a distributor of rare coins, announces the sale of some of the world's oldest silver coins — minted in the ancient Greek province of Lydia, the acknowledged birthplace of world coinage. Part of a hoard unearthed in the Middle East, these authenticated silver pieces are among the first 90% pure silver coins known in the history of mankind.**

A remarkable hoard find now makes it possible for you to own some of the world's oldest silver coins — and at a suprisingly low price. Each of these real ancient coins features a famous "archer" portrait of such Persian rulers as Darius and Cyrus, whose great empire dominated the civilized world from the 6th Century B.C. until conquered by Alexander the Great in the 4th Century B.C. Called "sigloi" in Greek, these coins are the type of "temple tax sheckels" cited in the Old Testament. The incuse reverse sides bear authentic countermarks made by moneychangers who tested their silver content up to 2,500 years ago. Each thick, oblong coin measures approximately 15mm long and weighs about half an ounce.

A surprising value

Similar ancient coins have carried coin catalog values of $100 or more, but because of our advantageous hoard purchase, ICC is offering these ancient silver coins to collectors and investors on a first-come, first-served basis at the following low introductory prices:

1 coin — $49.
2 coins — $98.
3 coins — $137 (save $10)
5 coins — $220 (save $25).
10 coins — $399 (save $91).
Limit 10 coins.

Add $3.75 postage and handling for one coin, or $5 for two or more.

Each coin will be accompanied by a certificate of authenticity attesting to its genuine pedigree and fine quality — plus a FREE presentation case, making it an ideal gift.

To order yours, call toll-free 1-800-451-4463 — 24 hours a day, 7 days a week (including Sundays). Please have your credit card handy. Or mail your check or money order to:
International Coins & Currency, Inc., Dept. 854, 11 E. State St., Box 218, Montpelier, Vermont 05602.

All coins are available for prompt delivery.

Cambrian stratigraphy has improved to the point where "it's there, but we haven't found it yet" becomes increasingly more implausible. Moreover, we have found an extensive fauna of soft-bodied Precambrian creatures (the Ediacara assemblage—see my column of February 1984), and they neither match in diversity nor seem ancestral to the Cambrian soft-bodied creatures of the Burgess Shale. In a strikingly new interpretation, Adolf Seilacher has argued that the Ediacara animals are not, as previously argued, ancestral to the Cambrian fauna, but a separate experiment in multicellular life, wiped out in a previously unrecorded mass extinction just before the Cambrian explosion. If this interpretation holds, then the Cambrian fauna must be new to the Cambrian (or we would have found its representatives in the Ediacara beds).

The second solution regards the unparalleled explosion of Cambrian body plans as a real and rapid event. Explanations for this reading come in two broad categories—traditional and conventional. (I suspect that the correct solution will combine a bit of both, but I profess strong fondness for the unconventional argument.)

The conventional theme, based upon a world run by Darwinian natural selection, holds that there never was a time quite like the Cambrian—and that the anatomical explosion was a response to this ecological uniqueness. Multicellular life of modern aspect had evolved but recently, and it faced an empty world, teeming with ways for making a living and ripe for exploitation. Ecosystems had room for everything—crawlers, walkers, burrowers, slurpers, predators, parasites, you name it—and life responded with an unparalleled seizure of opportunity, vigorously overshooting the mark (early experimentation) and then sorting out the best competitors (later standardization). Once exploited in the Cambrian explosion, such an opportunity could never arise again because the earth's oceans never became so empty. Even after the great Permian extinction, which removed 96 percent of all marine species by one estimate, no comparable radiation greeted the subsequent Triassic because at least one of every major design survived the debacle, and basic body plans did not disappear.

The unconventional theme does not deny this powerful impetus from an empty world, but argues that genetic systems, as well as environments, might have been different in the Cambrian. (The conventional explanation looks only to environments and implies that a similar explosion would occur now if a mass extinction ever emptied the oceans to earliest Cambrian leve of organic complexity and diversity.) U der traditional Darwinian views, mo phologies have histories that constra their future, but genetic material does n Genetic systems do not "age." Diffe ences in rates and patterns are respons of a similar material substrate (genes a their actions) to variations in environme that set differing pressures of natural s lection.

But perhaps this usual view is wron Maybe genetic systems do "age" in t sense of becoming "less forgiving of maj restructuring" (to cite a phrase from J. Valentine, who has thought long a deeply about this problem). Perhaps mo ern organisms could not spawn a rapid a ray of fundamentally new designs, no ma ter what the ecological opportunity.

I have no profound suggestions for t potential nature of this genetic "agin but simply plead that we bear such an ternative firmly in mind. Our explodi knowledge of development and the m chanics of genetic action should provi within a decade, the facts and ideas flesh out such a conception. Valenti mentions some possibilities. Were Ca brian genomes simpler and more flexibl Does the evolution of multiple copies so many genes, copies that then diver into a range of related functions (see la month's column on the homeobox), tie genomes into webs of interaction not ea ily broken? Did early genes have fewer teractions with others? Did early orga isms develop with more of a one-to-o translation of gene to product, permitti such animals to interchange and alt their parts separately? Most important, increased complexities and regularizati of development from egg to adult put brake upon potential changes of gre magnitude?

We cannot yet go beyond such cru and preliminary suggestions. I have no ing new or useful to offer in this area, bu wish to present, as a final point, an arg ment for the unconventional view that h been overlooked—one that strikes me important.

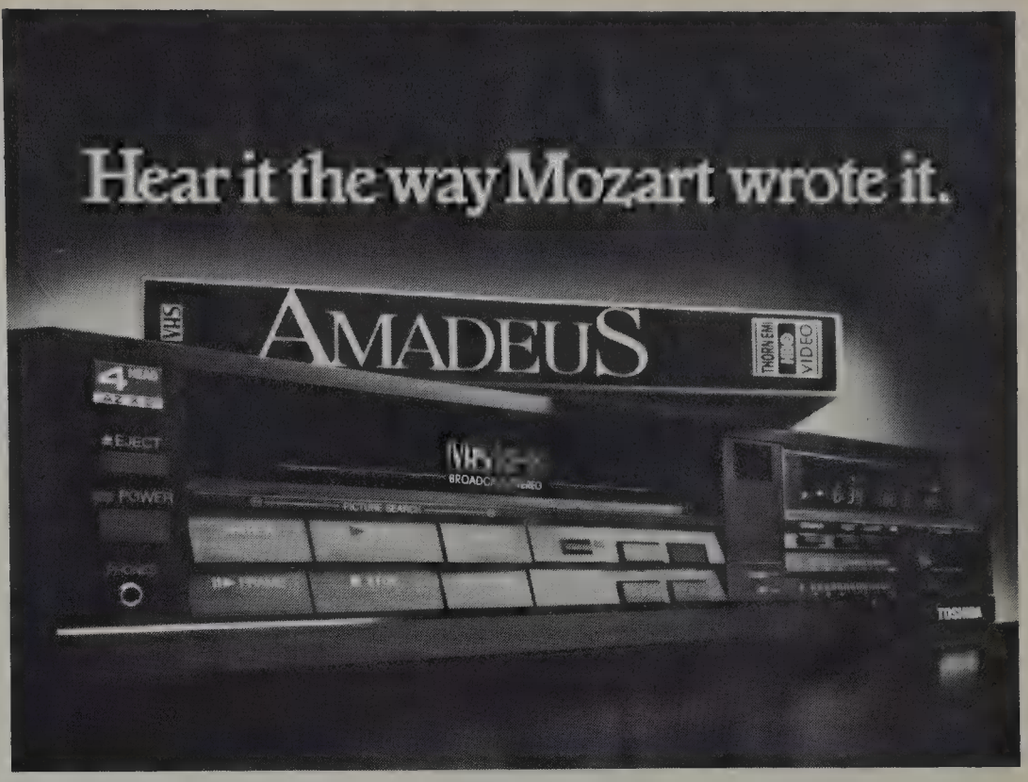
A false and usually unstated assum tion underlies our preference for the tra tional view that ecological opportun alone spawned the Cambrian explosi When evolutionists note that several un lated lineages react in the same way at t same time, we assume that some force e ternal to the genetics of organisms has p voked the common response (for the g netic systems are too unlike, and a simi push from outside seems the only plau ble common cause). We have alwa viewed the creatures that made the Ca

an explosion as unrelated in just this found way. After all, they included resentatives of nearly all modern la, and what could be more different n a trilobite, a snail, a brachiopod, and echinoderm. These morphological de- ns were as distinct in the Cambrian as y are today, so we assume that genetic tems were equally unlike—and the nmon behavior of all groups, that is, ir simultaneous vigor in evolving new igns, must therefore record the exter- push of ecological opportunity.

But I remind everyone that, particu- y if Seilacher's view of the Ediacara na holds (the claim for their nonan- tral nonlink to modern designs), then Cambrian animals, despite their diver- of form, were little removed in time m their union in a common ancestor. Cambrian animals may have sported a y similar genetic mechanism by virtue their strictly limited time of separate . No ties bind so strong as the links of eritance. In other words (and in the bio- ical jargon), the similar response of mbrian organisms may reflect the *ho- logy* permitted by a genetic system still d largely in common, not only the *anal- y* of a response by different systems to a mmon external push. Of course, life eded the external push of ecological portunity (I do not deny this part of the ditional claim), but its ability to re- ond may record a genetic heritage, then mmon and now dissipated.

This prospect suggests an intriguing re- erpretation of life's history. We know at the quirky and opportunistic paths of story shape the patterns of life's form d diversity through time. But we have sumed that the basic machinery (ge- tic systems and their response to natural lection) has operated in the same way, at ast since the evolution of our modern ayla. As continents wander in curious ths, but principles of plate tectonics re- ain the same, we have argued that or- nisms follow unique, directional, and nrepeatable pathways, but that material bstrates have no important history. But rhaps history is more pervasive than we ve thought. Perhaps we cannot escape s constraints and find a comfortable set underlying timeless objects that will enerate the uniqueness of observed re- lts from an unchanging core. Perhaps e core evolves too, in profound and dif- rent ways from the phenomena that it enerates. Perhaps history is the deepest ommon principle of all.

tephen Jay Gould teaches biology, geol- gy, and the history of science at Harvard niversity.



Now that movies come in hi-fi stereo, you can hear something that used to be unheard of: pure, high fidelity sound. But you need the right VCR. Toshiba's new M-5900 VHS. It has a dynamic range of 80 db, and virtually no wow or flutter. Plus 4 heads, 117 channel capability and wireless remote control.

So get Toshiba's hi-fi stereo VCR. And bring Mozart's Requiem to life.

Terror of the Trilobites

Paleontologists took a second look at a famed fossil site and unearthed the giant predator of the Cambrian period

by Derek E. G. Briggs and Harry B. Whittington

The discovery of British Columbia's Burgess Shale, as well as other fossil-bearing shales nearby, is one of the most important events ever to occur in paleontology. The shale's great value arises partly from the rare and exquisite preservation of soft-bodied creatures, but the find is even more remarkable because two-thirds of the fossils are from animals that were virtually unknown to science.

By studying these fossils, we are opening a large window on life 540 million years ago, during the middle of the Cambrian period. We have also solved some fascinating puzzles in the fossil record.

Since Charles Doolittle Walcott discovered the Burgess Shale three-quarters of a century ago (see Stephen Jay Gould's column, page 22), some 140 species from these rocks have been identified. Only about one-third of these species have the skeletons or shells commonly preserved in fossil-bearing rocks of the Cambrian period. The rest, being soft-bodied, are a fossil cache of great rarity and value and are still providing paleontologists with clues to middle Cambrian life and times.

In 1966, the Geological Survey of Canada began a reinvestigation of the Burgess Shale with a new excavation of Walcott's quarry. As part of the team, we have studied new, as well as previously collected, fossil specimens, among them the unusual creatures first described by Walcott. One of the most puzzling organisms, from the famed Fossil Beds of Mount Stephen, about two miles southeast of the Burgess Shale, had been described in 1892 by a paleontologist of the Canadian Geological Survey, J. Whiteaves. The name Whiteaves chose for the fossil, *Anomalocaris* ("unlike shrimp"), revealed his uncertainty about the animal's status. *Anomalocaris* fossils from both the Burgess Shale and Mount Stephen were tapered and segmented, with each segment bearing a pair of spines. Both Whiteaves and Walcott believed the fossils to be the body of a large, bivalved crustacean, from which both sides of the protective covering, or carapace, had become detached (a carapace was never found attached to the body). Walcott also described a "jellyfish," a flattened, circular structure with thirty-two radial divisions, as well as a large, isolated appendage bearing a long, comblike series of blades, each with an array of spines. This limb, informally dubbed appendage F, was adapted for capturing prey. Because it was jointed, Walcott guessed that the limb belonged to an arthropod. Arthropods, such as modern insects and crustaceans, have an exoskeleton, segmented body, and jointed limbs. Walcott even assigned the limb, incorrectly, to the genus *Sidneyia,* which also occurs in the Burgess Shale. Appendage F, the jellyfish, and the segmented *Anomalocaris* were thus classified, but nothing more was learned about them during the next seventy years.

Our observations make it clear that Whiteaves and Walcott were mistaken when they labeled the segmented *Anomalocaris* as the body of an arthropod. None of the fossils shows any traces of a gut, a part often preserved in other animals in the shale. Moreover, the joints are hinged in a most unusual manner for those supposed to be of the trunk skeleton. We realized that what Whiteaves, Walcott, and later authors thought to be a complete body was just an isolated limb. This "tip of the iceberg" led us to speculate on the size of the whole organism. Some of the limbs reached lengths of eight inches—gigantic by Cambrian standards.

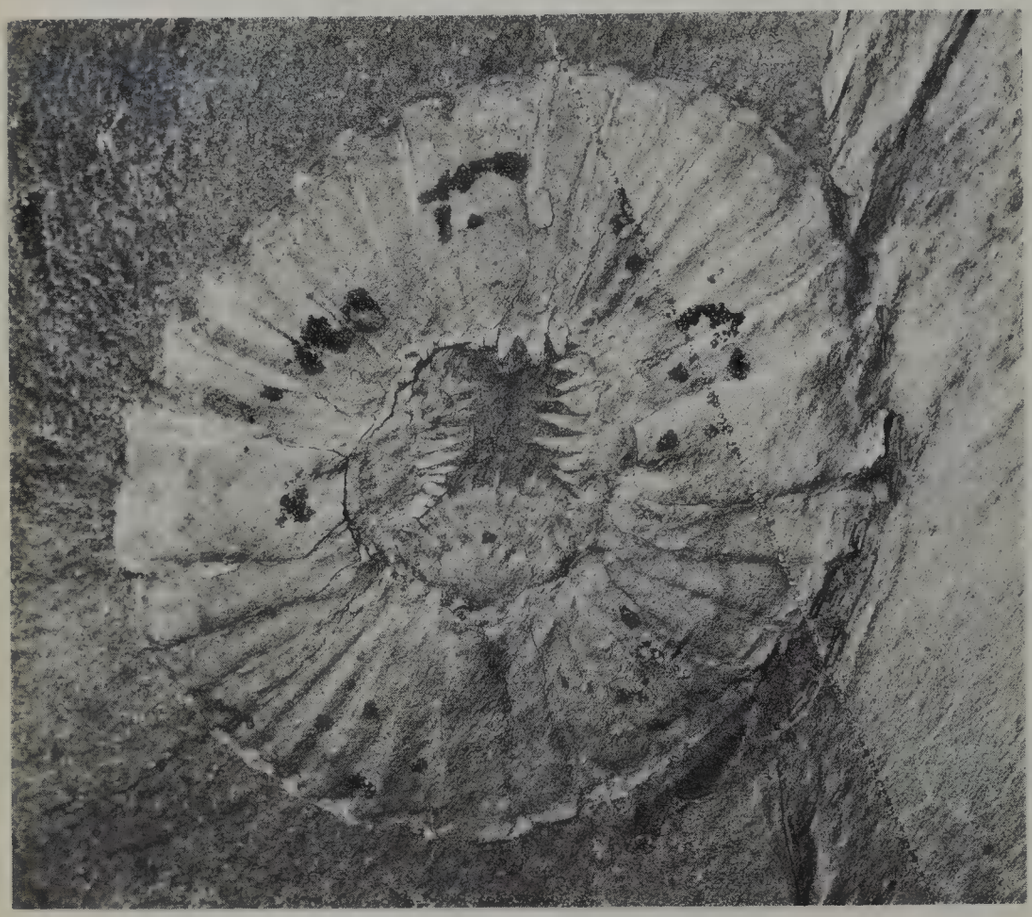
In 1981, Whittington began work at Cambridge University on specimens of a large undescribed animal from Walcott's collection and on one specimen from the Geological Survey of Canada collection. As he applied a dental drill to the stone overlying the Geological Survey fossil, he discerned a pair of *Anomalocaris* limbs attached to the specimen's head.

Further investigation fleshed out the creature and solved longstanding puzzles. When we examined Walcott's material, we saw that other specimens had preserved head limbs that matched appendage F. One had a circlet of plates where the mouth ought to be, a ring identical to Walcott's jellyfish. Its consistent position in a number of specimens ruled out its accidental superimposition on any other fossil animal. Not a jellyfish, but part of the body, the ring was a circlet of jaw plates.

The Cathedral Crags of British Columbia, below, are the remains of a massive limestone reef deposited by millions of generations of lime-secreting marine algae. A belt of limestone fringed the American continent in the mid- to late Cambrian, 540 to 505 million years ago. The Burgess Shale animals lived on and in muddy sediments that accumulated along the reef front.

All photographs by Derek E. G. Briggs and Harry B. Whittington

A fossil of an Anomalocaris *jaw, below, reveals a ring of jaw plates and an inner battery of teeth. The jaw plates are more often preserved than soft parts of* Anomalocaris *because they are more resistant to decay. The giant of the Cambrian period,* Anomalocaris, *right, reached lengths of eighteen inches. The jaw circlet and the grasping appendages on the head indicate that the animal was a predator, while the flat lobes flanking the trunk (incomplete due to breakage of the slab) attest to its swimming skills.*



The largest of the complete *Anomalocaris* specimens is about seven inches long, but the size of isolated limbs and jaw plates leads us to believe that individuals reached lengths of eighteen inches. This animal is the largest Cambrian creature ever found and was the giant predator of its time. We think two similar species existed, one having a pair of *Anomalocaris*-type limbs at the front; the other, a pair of appendage F's.

The relative abundance of isolated limbs and jaw circlets indicates that they were more resistant than the rest of the body to decay. These parts are rarely found in association, however. Limbs and jaws, shaped respectively like hollow tubes and disks, would behave very differently when carried by water currents.

Were soft-bodied animals, though scarce in the fossil record, actually common denizens of the ancient Cambrian environment? While the Burgess Shale, the only site yielding complete specimens of *Anomalocaris,* is exceptional, evidence indicates that the assemblage of animals the rock contains was typical of Cambrian seas. The discovery of soft-bodied Burgess Shale animals at more than a dozen new localities, nine yielding parts of *Anomalocaris,* provides further evidence that the Burgess Shale fossils are widespread and representative of Cambrian life.

How did *Anomalocaris* operate in its Cambrian world, and how did it interact with the animals sharing its habitat? Our reconstructions show it to have been an agile swimmer and an efficient predator. Spiny, segmented limbs flanked the jaw plates, and a pair of large eyes sat well back on the sides of the head. The trunk bore a series of large overlapping fins, or lobes; overlying these lobes were possible gills. The lobes probably moved up and down in succession, creating a propulsive wave running the length of the trunk; thus the animal swam like a fish with a long lateral fin, such as a stingray's. The body outline also resembles that of a cuttlefish, which also uses undulations of the lateral fins for maneuvering, although jet propulsion is its normal mode of swimming. The triangular, horizontal lobes of *Anomal caris* could hardly have been used as oa to paddle the animal along because th would not fold or collapse during a rec ery stroke, to reduce drag in the manner a "feathered" oar. Rather, *Anomaloca* was unique in swimming by generating wave with a series of separate lobes rath than along a continuous fin. The dr caused by the gaps between the lobes m have been offset by the thrust created water was forced out from between the The animal may have been coordinat enough to reverse the propulsive wave a swim backward, to adjust the waves on posite sides of the trunk to turn, and ev to hover.

Anomalocaris was well suited to life as carnivore. The pair of front limbs cap-red prey and pushed it toward the cir-et of plates making up the jaw. Its grasp-g appendages and swimming skills early enabled *Anomalocaris* to capture imals of the sea bottom.

The most abundant bottom dwellers eserved in the Cambrian fossil record e trilobites, marine creatures that had a rd exoskeleton divided into three sec-ons and that grew, like modern crusta-ans, by molting, thereby producing nu-erous fossils. Although preserved traces *Anomalocaris* gut contain no recog-zable prey fragments (such as broken ts of shell), trilobites found at a number of Cambrian localities, including the Fossil Beds on Mount Stephen, are marked by bites, usually in the tail shield. These trilobites are the survivors of attacks, much as seals or other marine mammals bear evidence of shark or *Orca* strikes. The wounds have healed around the margins; less fortunate victims were presumably bitten in critical areas. While *Anomalocaris* is likely to have fed extensively on the abundant arthropods that lacked the heavily mineralized skeleton of trilobites, its bulk and efficient toothed jaws make it probable that Cambrian trilobites were part of its diet.

Circumstantial evidence also suggests a predacious interest in armored animals. Because the "teeth" did not meet, the jaw could not have bitten clean through prey but may, in combination with the appendages, have worked like a nutcracker to break the exoskeleton of trilobites. The shape and overlap of the jaw plates form two wider openings, aligned diagonally across the circlet. If a large trilobite was turned on its side and the edge pulled into one of those openings, the resultant break would be shallow. The bite itself was probably in the form of an asymmetric W. Some marks inflicted on trilobites found at Mount Stephen and in middle Cambrian rocks in Utah (where *Anomalocaris* also occurs) have such an outline.

Predation is important to an understanding of ancient ecology because the food chain helps determine the structure of biological communities. The jaws and appendages of *Anomalocaris* attest to its carnivorous role; the bitten trilobites show that it (and perhaps other large predators) were capable of breaking mineralized skeletons, a process known as durophagy. Other animals from the Burgess Shale also had limb structures or gut remains suggesting they were predators. The limbs of one fossil trilobite indicate that it was a predator in its own right; other trilobites were scavengers, deposit feeders that grazed on organic matter from the sea floor, or filter feeders that gathered food particles suspended in the water. Ways of eating, such as carnivory, and ways to keep from being eaten proliferated. Even by the Cambrian, then, predation was a vital factor controlling the structure of communities and promoting the evolution of protective strategies. The pressure to develop defense tactics ultimately served at least some of the prey well, as they flourished throughout the Cambrian period and beyond. The armored trilobites, for example, survived about another 300 million years into the Permian period.

The tough exoskeleton of trilobites, such as Ogygopsis, *below, was no guarantee against attack. The specialized jaws of* Anomalocaris *may have acted as a nutcracker to penetrate the hard covering. The bite mark on the right side of this animal's tail shield tells the story of the trilobite that got away.*

Taxonomy, the classification of animals into related groups, is often a matter of great debate for paleontologists. Much of the discussion of arthropod evolution has centered on the problem of whether the presence of a particular character in two groups indicates relationship (common ancestry) or independent evolution of a trait in response to similar environmental and selection pressures (convergent evolution). *Anomalocaris* provides striking evidence that at least one important character of arthropods, the jointed limb, could have evolved independently in two or more major groups of animals.

Apart from the limbs and segmentation of the trunk, *Anomalocaris* is unlike any

An astounding variety of shelled and soft-bodied animals inhabited Cambrian seas.

1. *Ottoia,* priapulid worm
2. *Burgessochaeta,* annelid worm
3. *Louisella,* priapulid worm
4. *Hyolithus,* mollusklike animal
5. *Aysheaia,* arthropod
6. *Leanchoilia,* arthropod
7. *Nisusia,* brachiopod
8. *Opabinia,* affinity uncertain
9. *Dinomischus,* affinity uncertain
10. *Waptia,* arthropod
11. *Yohoia,* arthropod
12. *Canadaspis,* arthropod
13. *Molaria,* arthropod
14. *Pikaia,* chordate
15. *Marrella,* arthropod
16. *Scenella,* mollusk

arthropod. The combination of plated jaw and overlapping trunk lobes and consequent mode of swimming precludes the assignment of *Anomalocaris* to any living group. If we discovered such a creature in the deep sea today, we would readily designate a new phylum to house it.

Anomalocaris was one of a great mosaic of body forms that evolved during the late Precambrian/early Cambrian, the time of the first great adaptive radiation of multicelled animals, arguably the most important event in the entire evolutionary course of multicelled life. Early in this radiation, or filling of ecological niches by new forms of life derived from common ancestors, competition between different kinds of animals may have been limited, giving rise to the evolution of an unsurpassed variety of body plans. But when a phylum (such as that including *Anomalocaris*) became extinct, no new, unique group seems to have replaced it. Rather, the vacated niche was filled by diversification of other existing stocks, and the range of phyla was thereby reduced. Why some phyla succeeded and others failed—why arthropods, *Anomalocaris*'s prey, should include the most abundant and diverse living groups, such as modern insects, while *Anomalocaris* disappeared after the middle Cambrian—is unclear. Chance may have played a role, but we surmise that the body plan of *Anomalocaris,* with one pair of jointed limbs, overlapping lobes, and radial jaw, had less long-term adaptive potential than that of arthropods, with serial repetition of branched limbs.

Modern perception of the diversity of animals in the Cambrian depends largely on the quality and extent of the fossil record. The Burgess Shale helps balance a fossil record biased toward animals with hard parts and offers a rare, three-dimensional view of Cambrian life. Trilobites, so abundant as fossils, were just a part of a broad scenario and were stalked by the *Tyrannosaurus rex* of their time. The Burgess Shale has revealed the unsuspected abundance of soft-bodied Cambrian creatures and has shown that more than 500 million years ago, forces familiar today, such as predation, were already shaping the evolution of ancient life. □

A "Tree of Life" Grows in Brazil

In the Brazilian state of Maranhão, the poor carve out a living from an all-purpose palm

By Anthony and Suely Anderson

Anthony Anderson

Agriculture has never been an easy proposition in the humid tropics. Trying to grow a crop and simultaneously hold off the bewildering number of plants that invade any cleared area requires enormous effort. Of course, many of the people who traditionally farm in the tropics are shifting cultivators. These growers minimize their efforts by clearing small patches of forest, which they use for a year or two and then abandon. The fields are quickly taken over again by the forest.

This ephemeral form of agriculture works fine when population densities are low. But in recent years more and more settlers have poured into the tropical lowlands. At the same time, much land has fallen into the hands of a wealthy few. The result is that shifting cultivation has broken down: with more people using less land, farmers cannot give sites a long enough rest. This reduces their harvests and eventually degrades the soil.

In many places, ranchers have taken over. They acquire large tracts of forest and clear them, turning them into pastures for cattle. Like the cultivated land, these areas are subject to degradation—from erosion, trampling of soil, and weed infestation. And ultimately, both these forms of land use have had the same result: wide areas of some of the most biologically rich places in the world have become agriculturally unproductive and economically impoverished.

But in frontier areas along the southern edges of the Amazon Basin, and particularly in the Brazilian state of Maranhão, nature has found a way to resurrect the lost land. Abandoned fields and croplands have been taken over by palm trees. The palm tree known as babassu (*Orbignya phalerata*) is a stubborn competitor that keeps other species from gaining a foothold. In fact, the forests it forms are so pure and uniform that travelers who have never seen them before often mistake them for plantations. That is a reasonable conclusion because local inhabitants can often be seen working among these palms, gathering fruit and cutting leaves.

But the immense stands of babassu in Maranhão occur naturally, and most of the people who use them are landless. For these people, babassu palms are a crucial source of food, fuel, shelter, and income. The story of where the palm came from and how people have come to depend on it tells something about life in frontier areas of the Brazilian Amazon and how human activities there, in conjunction with a natural process, may point to more successful ways to use land in the tropics.

Pure stands of babassu palm probably started to form in Maranhão after the arrival of Europeans in the 1600s. The colonists set up rice, cotton, and sugar cane plantations on bottom lands all over the state. The stands were probably not extensive initially and were largely confined to bottom-land areas. But in 1888, slavery was abolished and the plantation economy collapsed. Former slaves, and later their descendants, spilled out of the lowlands and entered the original forests, which they cleared. Wherever these shifting cultivators left a field fallow, babassu took over and turned the fields back into forests. In time, pure stands of the palm spread across the landscape.

Today babassu palm forests cover extensive areas of Brazil. In Maranhão, where we recently spent two years studying the palm, these forests now occupy an area roughly equal to the state of Virginia.

How do young babassu palms capture a deforested site? To understand that, one first has to know something about the palm's ecology in the uncut forest. There are tremendous numbers of young ba-

Randall Hyman

Human colonization of the Amazon Basin has sped the spread of the babassu palm, for wherever original forests are cut down for farming, babassu eventually takes over. Almost everything that grows on the plant has proved useful to local people. At right, a family heads into a hilly forest to gather babassu fruit. The husks of the fruit are used to make charcoal, below. People burn the husks in a shallow pit and continue to add organic material until carbonization occurs. In one district of Maranhão, more than 96 percent of the homes use babassu charcoal as the sole energy source.

Anthony Anderson

bassu plants growing in the primary forest. When we surveyed an undisturbed, species-rich forest in central Maranhão, we found more than 2,500 juvenile palms per acre. One reason the babassu palm does so well there is that its fruit has a two-inch-thick husk. It takes five and one-half tons of force to break one open; no mammal currently in Maranhão (or anywhere else in the American tropics) has that kind of strength. Only human beings with axes can get at the oil-rich seeds.

Today the only important nonhuman seed predator is the bruchid beetle *Pachymerus nuclearum*. The larvae of this beetle skirt the thick fruit wall and slip in through the germination pores located at the base of the fruit. Still, they rarely eat all the seeds. Our studies have shown that although 70 percent of the fruit are colonized by bruchid beetles, only about 20 percent of them lose all their seeds. At least one seed per fruit usually escapes predation and is able to germinate. In other words, just about every single time a babassu fruit drops in the primary forest, the result, sooner or later, is a new palm tree.

Germination begins approximately three months after a fruit falls and—also key to the success of the juveniles in the forest—is actually enhanced in the shaded understory. But babassu grows extremely slowly. We found that palms growing in a mature forest often didn't start reproducing until they were more than 70 years old. Babassu apparently can withstand long periods of low light. And it lives an unusually long time—the oldest tree we found was, by our estimates, 184 years old. Rather than usurping resources by rapid dispersal or growth, the babassu palm simply outlasts its competitors.

When farmers come in to cut and burn a forest, all the vegetation on the surface is destroyed and few plants can regenerate quickly. But the babassu palm has an unusual feature not shared by most other species—its apical meristem, the part of the plant that is actually growing, is pushed underneath the surface during germination. This adaptation allows most juveniles to survive being cut and burned, even if their aboveground portions are completely destroyed. We had firsthand experience with babassu's extraordinary capacity to regenerate while setting up experiments that required removing all palms from a site. We cut the juvenile palms repeatedly, to no avail. Finally, in frustration, we attempted to eradicate them by driving wooden stakes into their underground palm hearts. But the palms kept regenerating, which forced us to conclude that young babassu are harder to kill than Count Dracula. And once they dominate a site, they are there to stay: at one site that had been cleared thirty-three years earlier, we found that the population of babassu was still increasing. Thus the babassu palm, a strong latent presence in the uncut forest, stands alone in the cleared forest.

For many people living in Maranhão the formation of pure babassu stands has been a blessing. In one rural district of the state, 86 percent of the households use babassu leaves as thatch for their huts. From July to December, the dry season in Maranhão, people scale the palms and remove their leaves, which are often twenty-four feet long. When leaves are harvested every four years, it seems to have little effect on the tree's growth, although fruit pro-

duction drops off the following year. Aside from thatch, people use the leaves to make baskets, rugs, mats for drying grains, fans for tending fires, and sieves for sifting cassava flour and rice. In addition, they make fences, window frames, platforms for herb gardens, birdcages, even fish traps. Hunters use the leaves to make blinds when they are after agoutis, pacas, and porcupines, all of which feed on babassu fruit. Finally, cattle and donkeys feed on the leaves of babassu during dry spells.

The trunks of babassu palms are often used for construction work. People build small bridges and benches out of them. The trunks also attract weevil larvae, which local people fry and eat. People also eat the bruchid beetle larvae that attack babassu seeds. When fried, these larvae taste like bacon and are considered a delicacy. After felling a palm, people sometimes extract its heart and feed it to pigs.

Babassu fruit is also amazingly useful. In the state of Maranhão alone, 300,000 families participate in a cottage industry devoted to extracting the oil-rich kernels from the fruit, which is harvested during the dry season. Since men are usually busy clearing and burning agricultural plots at this time, most of the people who break babassu fruit are women and children.

The kernels extracted from the fruit have many uses in the home. People make babassu "milk" by roasting kernels, then crushing them in a mortar and mixing them with water. This liquid is then strained. The milk—and its mineral composition is similar to that of mother's milk—is fed to infants. To make oil, the kernels are roasted, crushed, and cooked; the oil is then skimmed off the surface. When we surveyed local households in our study area, we found that 54 percent of the people used homemade babassu oil for cooking and soap production. Even the residue from these domestic products has a use: it provides a nutritious feed for pigs and chickens.

The husks from babassu fruit are not thrown away—these dry shells, like everything else about babassu, are a valuable commodity. The husks consist of a fibrous outer layer (the epicarp), a starchy middle

M. J. Balick

An Apinaja Indian woman, below, peels off the starchy mesocarp of babassu fruit. This middle layer is used to make flour. The mat she is sitting on and the basket next to her are made from babassu leaves. At right, local women break the fruit to get at the oil-rich kernels. These seeds are also roasted, crushed, and mixed with water to make a milk substitute.

Randall Hyman

layer (the mesocarp), and a woody inner layer (the endocarp). Livestock eat the mesocarp; people also use it to make flour for cooking. The rest of the husk is made into charcoal. Husks are placed in a shallow pit and burned in a hot fire. As the fire burns, people continue to add more debris and this gradually promotes carbonization. In one district of Maranhão, we found that 96 percent of the homes used babassu charcoal as their exclusive source of fuel. People frequently make charcoal in the evening because the smoke is an effective insect repellent. And in certain areas of the Amazon Basin, the fruit of this all-purpose palm is used to smoke rubber.

Breaking into a babassu palm fruit is no easy task. People place the fruit on top of an upturned ax blade and beat it with a club until it breaks. A fruit breaker has to hit the fruit an average of twenty-six times before it splits, yielding three to five kernels. With this technique, a fruit breaker can get about nine pounds of babassu kernels each day. Most of the kernels are sold to local industries, which use them to produce oil, soap, and feed cake. Prices fluctuate wildly, depending on market conditions and the number of middlemen involved in the sale. But regardless of the price level, a fruit breaker rarely makes more than a dollar a day. Perhaps for this reason, 93 percent of the people who gather and break the fruit of babassu palms belong to the poorest class in Maranhão—the landless.

For people who have few economic options, gathering and breaking fruit is sometimes the only way to make a living. Many of the women who work with babassu are widows or are separated from their husbands. They find that the work, while not particularly lucrative, is suitable for other reasons. They can do it after they have finished their housework and taken care of their children. When the children get older, they join their mothers in gathering and breaking fruit. Families ofte stockpile fruit in the home and extra kernels during periods when the fruit ha vest is small. This gives them a mode source of income throughout the year.

For all of these reasons, babassu has b come a contemporary "tree of life" in M ranhão. But the palm has also found i way into the market economy and the ke nels are used in scores of local industrie Until recently, these industries were th largest single source of tax revenues in th state's economy. The oil, which makes u about 70 percent of the kernel weight, similar to coconut oil. The babassu oil i dustry, which has grown rapidly over th past sixty years, is currently the largest its kind entirely dependent on a wild plan

Other industrial products come fro the fruit's husk. Among these are ethano

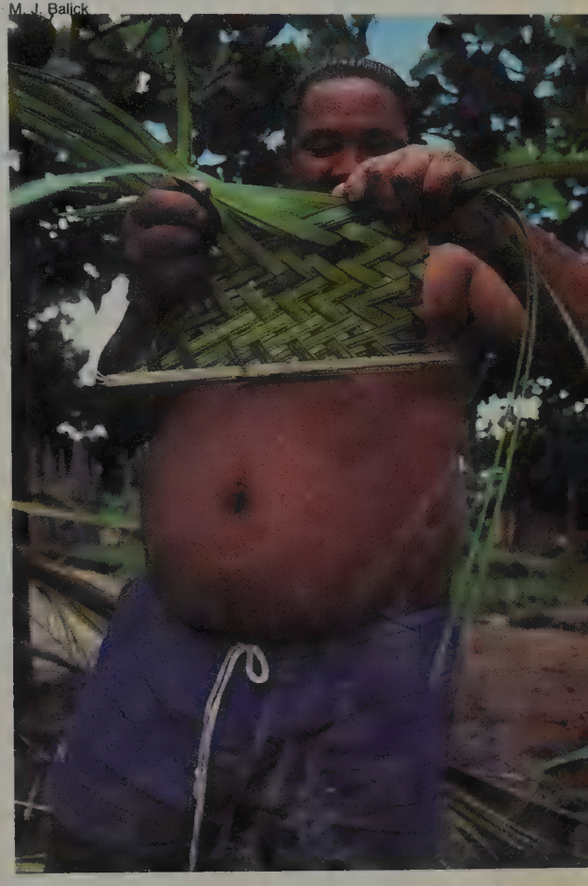
M. J. Balick



nethanol, coke, acetic acid, reactivated harcoal, combustible gases, and tar, vhich taken together have hundreds of industrial applications. For a long time vould-be manufacturers were stymied by he lack of machinery that could efficiently crack the hard fruit. But new machinery has recently been developed, making it possible to exploit a wide range of babassu products on a large scale.

As babassu increasingly becomes industrialized, some hard questions will have to be answered about managing the palm forest. For example, can the forests be managed as they are or should they be replaced by high-yield plantations? How these questions are answered will determine not only the future of the palm's place in the landscape but also the fate of the people who depend on it.

Because it tends to grow in pure stands, babassu is relatively easy to manage. Indeed, people have been managing it for a long time. In the northeastern state of Ceara, now-extinct aboriginal groups probably planted groves of babassu thousands of years ago, using seeds carried from hundreds of miles away. The Kayapó Indians of southern Amazonia plant babassu on shifting cultivation plots and tend them during the fallow period. These stands are often extremely productive, which makes us suspect that the Indians have selected high-yield strains. Ranchers and shifting cultivators frequently remove unproductive palms from the stands and thus have done some selecting themselves.

Not only is babassu easy to manage, but it also seems to have a crucial role in sustaining agriculture. Generally speaking, shifting cultivators will completely clear a forested site and then use the leaves and wood as fuel for a burn. The burn recycles nutrients and controls weeds, essential steps if farmers are to successfully grow their usual crops—rice, corn, beans, and cassava. After one or two years they abandon the site for a fallow period, during which the forest regenerates, eventually allowing another cycle of farming.

But with babassu, farmers never have to actually clear the area they want to plant. This is because babassu stands contain a tremendous amount of fuel in the form of leaves. In one stand, we found that the biomass of living leaves was thirty-one tons per acre. Thus, the leaves themselves provide ample material for a good burn. In a forest dominated by babassu, a shifting cultivator only has to thin the trees moderately, not cut them down. The babassu stand can thus be maintained during the entire agricultural cycle and provide a continual source of support for local people. And because the farmers are cutting leaves, not stems, the forest recovers quickly—producing enough fuel for a new

Anthony Anderson

A babassu palm stand is burned, below, to recycle nutrients and kill weeds, so that crops can be planted. Probably the most important feature of babassu is that it lends itself easily to shifting cultivation. Local farmers plant crops among the palm trees, and after a fallow period, they can use the leaves of the palm as fuel for a new burn and begin another cycle of planting. Thus even while they are farming babassu plantations, shifting cultivators continue to benefit from the wild palm. At right, children help bring in a load of fruit.

Peter May

burn in about four years. Ordinarily, a cleared forest takes seven or eight years to build up sufficient fuel for a burn.

In spite of these attributes, babassu is plagued by a number of serious limitations. First, the palm grows extremely slowly. Even under optimal conditions it takes a dozen years to mature. In addition, yields from the wild stands are low, averaging less than 1,800 pounds of fruit per acre annually. The African oil palm, by comparison, takes four years to mature and can produce 22,000 pounds per acre. Finally, collecting fruit from wild stands of babassu is extremely time consuming, which reduces the palm's competitiveness in both domestic and world markets.

These factors have led some people to suggest that plantations of the palm should be established using genetically improved strains of the plant. Efforts to domesticate babassu this way have already begun, and based upon our own research we believe it would certainly be possible to improve the palm for use in the marketplace.

This approach, however, would ignore the very attributes that make babassu unique. Pure stands of the palm form spontaneously, require little maintenance, and are already used by people. Intensive plantations of babassu would inevitably exclude the landless people now dependent on the plant. We believe babassu's productivity could be improved without introducing intensive, high-technology systems of agriculture and shutting out those who need it.

Some of the palm's limitations could be overcome through better management of existing stands. Selective thinning can enhance yields. Rather than gathering fruit from the ground as they do now, people could be encouraged to harvest fruit from the crowns. This would reduce losses. And if superior strains were developed, they could be planted in pastures or fallow areas or even in degraded sites in the Amazon Basin. Finally, if the current technology that has been developed for processing fruit could be adapted for use by local people, they could produce subsistence products much more efficiently and possibly sell the excess to distributors.

These suggestions might seem unconventional when compared with the standard approach that developers take in the Third World—which usually involves a complete transformation of the land and its native vegetation. But the current breakdown in land uses throughout the humid tropics calls for radical changes in the way agriculture is practiced. In places that are undergoing rapid settlement, the trick is not to maximize agricultural output but simply to maintain it. Stands of wild babassu palm, an extraordinary subsidy from nature, represent one solution to this problem. □

WE HID A SPORTS CAR INSIDE.

Forget everything you've previously believed about sedans: Big on the outside. Soft on the inside. And never ending stops at the pump. No more. Because the sedan has changed... into a sophisticated, streetwise performer named Dodge Lancer.

Lancer was designed with a new regard for the fun of the road. And a disregard for the commonly held notion that performance precludes practicality.

First, the fun.

Horatio Greenough's sculpture The Rescue *stood on the east portico of the U. S. Capitol from 1853 to 1958. By contrasting the roles of male and female, red and white, the sculptor celebrated the triumph of "civilization" over "savagery," but distorted the reality of captivity in frontier times.*

Architect of the Capitol

Captive Images

Stereotypes that justified colonial expansion on the American frontier were a legacy of a seventeenth-century war

by Pauline Turner Strong

As the white woman, baby clutched to her breast, cowers below, a towering frontiersman overpowers a tomahawk-wielding Indian. Entitled *The Rescue*, this marble sculpture by Horatio Greenough was commissioned by the United States Congress and installed in 1853 at the eastern entrance to the Capitol. Adapting classical forms to an American theme—the frontiersman is draped and helmeted—Greenough sought to create an image, as he wrote to the secretary of state, that commemorated "the triumph of the whites over the savage tribes, at the same time that it illustrates the dangers of peopling the country." He also intended that the sculpture serve as "a memorial of the Indian race, and an embodying of the Indian character."

As substantiated by its scale, execution, and placement, the monument does not depict the rescue of any particular mother and child. The marble figures embody mythic archetypes: the vulnerable white victims, the brutal Indian aggressor, the heroic male redeemer. The raised hatchet demonstrates the Indian's ferocious character: savagery threatens to dominate civilization by wrenching its weak and fledgling members from an orderly, protective environment and holding them hostage in the wilderness. This threat justifies not only the act of rescue but, ultimately, white expansion at Indian expense.

The iconography of *The Rescue* was a legacy of the late seventeenth century, a time when the New England colonies and the surrounding Algonquian-speaking peoples were embroiled in unprecedented violence. The height of conflict, from June 1675 to August 1676, was known to the English as King Philip's War, for Philip was the name the English gave their foremost adversary, Metacomet. Philip was the sachem, or leader, of Pokanoket (present-day Bristol, Rhode Island), the largest village in the Wampanoag alliance, one of several Algonquian groups in southern New England. During the war, Philip's forces captured some forty adults and children from frontier settlements. One, a clergyman's wife, wrote a remarkable account of her experience, published in 1682 as *The Sovereignty and Goodness of God, Together, with the Faithfulness of His Promises Displayed; Being a Narrative of the Captivity and Restoration of Mrs. Mary Rowlandson.*

Among the foremost popular works of its century, Mary Rowlandson's narrative initiated an iconography of captivity that eventually reduced complex colonial frontier history to the relationship between a white female captive and a red male captor. Ironically, however, Rowlandson's primary antagonist was not a man, but a powerful woman. And Rowlandson's sufferings and those of her compatriots pale in comparison to the devastation several thousand red captives suffered at the hands of the English.

Mary Rowlandson left a vivid and detailed record of her twelve weeks of captivity because, as a devout Puritan, she considered the most mundane occurrences to be signs of the will of God. Her observations are especially significant historically because the Algonquians, recognizing that a clergyman's wife was an exceptional prize, strategically placed her in the care of one of their major leaders, the Narragansett sachem, Quanopin.

Mary Rowlandson thought highly of her "master," Quanopin, calling him "the best friend that I had of an Indian both in cold and in hunger," but she despised his

The Newberry Library

wife Wetamo. A "severe and proud dame," Wetamo seemed to delight in playing upon her captive's anxieties and arbitrarily depriving her of food, fire, shelter, and the solace of the Bible. Although Mary Rowlandson realized that Quanopin was a sachem and learned that Wetamo's sister was Philip's wife, she was unaware that her "mistress" was, in her own right, the sachem of the Wampanoag village of Pocasset (on the modern sites of Fall River, Massachusetts, and Tiverton, Rhode Island).

Wetamo was one of several female sachems who came into prominence during King Philip's War. "Squaw sachems," as the English called them (using the Algonquian term for woman), could attain authority as the widows of sachems; Wetamo, however, like a male sachem, achieved leadership through descent within a ruling patrilineage. Whether male or female, the Algonquian sachems governed their villages through persuasion, regulating internal matters such as the production of food, the distribution of resources, and the resolution of disputes. Sachems also established alliances with other villages through diplomacy, trade, tribute, and marriage. During times of hostility, leadership might pass to a separate authority with demonstrated proficiency in warfare, but sachems could be influential in war as well as in peace; this was the case with Wetamo, whose warriors reportedly numbered three hundred at the outbreak of the war, arousing great fear among the English colonial settlers.

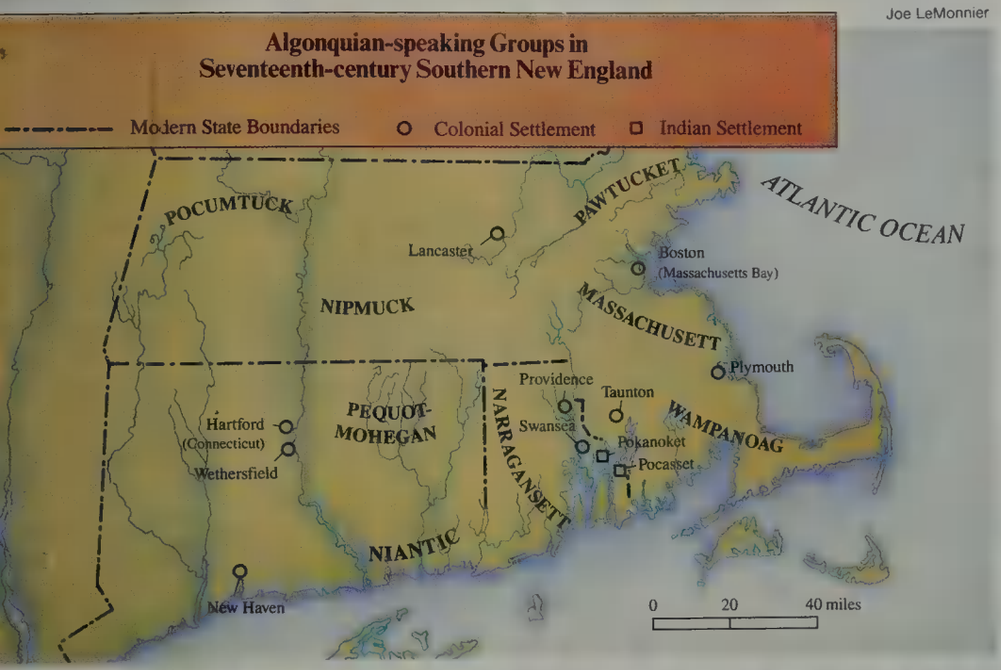
Wetamo, like Quanopin, was drawn into King Philip's War through a series of events that preceded the conflict. Philip's father, Massasoit, had signed a treaty of friendship with the Pilgrims in 1621, shortly after their landing at Plymouth. To the Wampanoags, recently decimated by a European-borne epidemic, the new colonists represented valuable support against their enemies to the west, the Narragansetts. The Pilgrims, in turn, perceived the alliance as a protectorate allowing them to establish a claim over Wampanoag land (although Massasoit insisted on his right to sell land to other colonies). The alliance survived until Massasoit's death in 1662, preserving the Wampanoags from the fate of the Pequots and Narragansetts, who suffered ruthless colonial attacks in 1637 and 1643, respectively.

The alliance became particularly significant to the Pilgrims after the Restoration of 1660, when Plymouth had to defend its land claims before Charles II in the face of competing claims from the Massachusetts Bay, Connecticut, New Haven, and Providence colonies, all established in the sixteen thirties and forties. Plymouth pressured Massasoit's son and successor, Wamsutta (Alexander, to the English) to sell land only to Plymouth. Indeed, in 1664, after Alexander had initiated independent land dealings with Providence, he was seized at gunpoint and forced to march to Plymouth to answer for his actions. Already ill, Alexander died after this episode and was succeeded by his brother Philip. Alexander's widow was none other than the "squaw sachem of Pocasset," who took the name Wetamo to mark her change in marital status. Philip married Wetamo's sister, thus preserving the alliance between the towns of Pokanoket and Pocasset.

Relations with Plymouth worsened during Philip's tenure as sachem, as Plymouth encroached on Philip's authority, as well as on his people's land. In 1667 Plymouth established a new town, Swansea, on land claimed by both Philip and Provi-

here are no authentic portraits of the Algonquian leader Metacomet, or Philip, the dian protagonist in what the colonists called King Philip's War. Paul Revere's oodcut of Philip, left, published in 1772, was based on a famous 1710 painting of a ohawk. The map below shows the locations of the major Algonquian groups in uthern New England at the time of King Philip's War (1675–1676). Important ttlements that featured in the war's history are also shown. The woodcut, bottom, is om the 1791 edition of Mary Rowlandson's narrative of her captivity by the Indians ring King Philip's War. It depicts the attack on Lancaster, Massachusetts, during hich she was taken hostage.

Joe LeMonnier



e Newberry Library

dence. Philip protested, only to see Swansea expand. Four years later, after Wampanoag men brandished weapons near Swansea, Philip was forced to sign a treaty acknowledging subjugation to colonial authority. This marked a significant loss of independence for the Wampanoags, who had considered themselves subject only to the king of England. Rumors of an Indian conspiracy against the colonists had surfaced periodically since Alexander's brief tenure, and more than a decade of mounting tension finally climaxed in 1675, when a Christian Indian who had accused Philip of conspiracy was murdered. By June, Plymouth had declared war on Philip and fighting began in the troublesome Swansea area.

Wetamo, who controlled nearby lands that several of the colonies desired, allied herself with Philip early in the war, parting with her husband, who maintained his allegiance to the English. She supplied provisions and forces for Philip's campaign, and at the end of June, Philip fled from his territory to hers, where together their peoples hid in the Pocasset cedar swamp. Driven out at the end of July, Philip headed north to seek an alliance with the Nipmuck, while Wetamo and her people took refuge to the west among the Narragansetts. There she became Quanopin's third wife, sealing an alliance between their peoples.

Although the Narragansetts had been enemies of the Wampanoags, the refugees could expect they would be adopted and furnished with houses, goods, and fields. Such was the indigenous pattern of warfare: while certain captives, generally the warriors, might be tortured and executed and others might be held for ransom, a displaced population was commonly adopted. Each of these alternatives was a way of compensating those who had lost relatives in war.

In July 1675, the English managed to get four powerless Narragansetts to promise that the Wampanoag refugees would be handed over. The legitimate leaders stalled; although eager to maintain neutrality, they knew from past experience that refugees could expect harsh treatment from the colonists. After the con-

Popular, cheap, and readily available, dime novels were first marketed in 1859. Novels such as The Long Trail, *below, sensationalized and spread stories of capture by Indians. The theme of rescue, which illustrates* Simple Phil, *opposite page, echoes Greenough's sculpture by casting the white woman as victim, the frontiersman as hero, and the Indian as depraved villain.*

Rare Book Division, The New York Public Library

quest of the Pequots in 1637, the Narragansetts had seen the several hundred Pequot survivors of a horrifying slaughter driven from their lands and consigned to slavery in the colonies, among Indian allies of the English or, in the case of at least fifteen boys and two women, in the West Indies. For five months the English pressed the Narragansetts to return the Wampanoag refugees, all the while confirming the Narragansetts' worst fears by selling several hundred Algonquians to slave traders heading for Spain and the Azores and retaining another hundred as domestic slaves. The majority of these unfortunates were at peace when they were captured or had voluntarily submitted themselves to colonial authority.

In December 1675, using the Narragansetts' protection of the Wampanoags as a pretext to conquer land they had long coveted, the United Colonies of Plymouth, Massachusetts Bay, and Connecticut (which now encompassed New Haven) joined in a massive attack on the Narragansetts' major swamplands stronghold, killing from three hundred to six hundred men, women, and children. (Dissident Providence—allied to the Narragansetts and excluded from the United Colonies—was not involved in the attack.) This, the Great Swamp Fight, forced the majority of the Narragansetts into the hostilities. Quanopin took a leading role in a series of offensive strikes against frontier towns. The first of these, an attack in mid-February on Lancaster, Massachusetts, was the one in which Mary Rowlandson was captured, along with three of her children and as many as twenty neighbors.

Mary Rowlandson's suffering during captivity was profound: she witnessed the deaths of her wounded six-year-old daughter, her sister, and a number of her neighbors; she was separated from her husband and her other children; she withstood the cold, hunger, and grueling travel that were the lot of her displaced captors; and she endured the hostility and torments of a besieged squaw sachem. Her ability to convey these experiences in simple and vivid prose contributed to the enduring popularity of her narrative, which has gone through forty editions and numerous anthologies in the three centuries since its publication. But her success in achieving publication (she was only the second woman to do so in New England) and initiating an influential ideology of captivity was especially tied to her penchant for interpreting the entire affair as an example of "the strange providence of God" toward his chosen people.

In her narrative, Mary Rowlandson

Rare Book Division, The New York Public Library

ays no attention to her captors' griev-nces or to possible motivations for their ctions, whether abusive or merciful. In-tead she presents her captors as instru-nents of Providence intended to provide ier with a spiritual trial and an opportu-nity for redemption. The numerous kindnesses of Quanopin, Philip, and oth-ers, as well as the complete lack of sexual harassment, are, to Mary Rowlandson, ev-dence that God was restraining the Indi-ans' innate depravity. Conversely, she sees he taunts and deprivations she suffered at he hands of Wetamo as confirmations of hat depravity—indeed, as signs of Weta-mo's subservience to that diabolical mas-ter, Satan.

In reality, the disparity between Quano-pin's and Wetamo's treatment of Mary Rowlandson had a more mundane basis. Apparently the couple disagreed as to the value of their captive, with each following an alternative cultural pattern. Quanopin was primarily interested in using Mary Rowlandson as a bargaining chip, while Wetamo assumed a role (common to fe-male lineage heads among northeastern Indians) of abusing her captive as a way of compensating herself and her lineage for heavy wartime losses.

Wetamo's hostile stance was no doubt exacerbated by Mary Rowlandson's fail-ure to recognize Wetamo's status and her refusal to defer to her mistress as readily as she did to her master. The product of a patriarchal society, Mary Rowlandson in-terpreted Wetamo's authoritative stance as vanity and insolence. She openly dis-obeyed her orders—refusing, for exam-ple, to hand over a piece of her apron for use as a child's loincloth—and was critical of her for "bestowing every day in dressing herself near as much time as any of the gentry of the land."

In April 1676, about two months after the attack on Lancaster, two Christian Al-gonquian intermediaries were sent to Phil-ip's camp to negotiate for the release of the English captives. When they arrived, "though they were Indians," Mary Rowlandson "got them by the hand and burst out into tears," inquiring after her husband and friends. Early in May, after three rounds of negotiations, Mary Rowlandson was returned to the English in exchange for a ransom payment. Her fourteen-year-old son and ten-year-old daughter, along with about twenty other English captives, were ransomed during the summer. Their home and village hav-ing been destroyed, the reunited Rowlandson family lodged with friends until, in the spring of 1677, the Reverend Mr. Rowlandson received a new pulpit in Wethersfield, Connecticut.

In contrast, the months after Mary Rowlandson's ransom were disastrous ones for Philip and his relatives. The ma-jor Narragansett leader, Quanopin's cousin, was captured and killed early in April by Indian allies of the English. Quanopin took over the leading role in June, but was captured in mid-July, and the following month he was court-martialed and shot for treason against the king of England. Wetamo and her three dozen remaining followers were am-bushed while trying to return to their home at Pocasset. As the tale was told by Rev. Increase Mather:

> Only the *Squaw-Sachem of Pocasset*, who was next unto *Philip* in respect of the mis-chief that hath been done, and the blood that hath been shed in this Warr, escaped

Wadsworth Atheneum, Hartford

The Death of Jane McCrae *was painted by American artist John Vanderlyn in 1804. The artist used conventional imagery, such as the upraised tomahawk and highlighted contrasts in sexuality and ethnicity.*

alone; but not long after some of *Taunton* finding an Indian Squaw in *Metapoiset* newly dead, cut off her head, and it happned to be *Weetamoo,* i.e. *Squaw-Sachem* her *head.* When it was set upon a pole in *Taunton,* the Indians who were prisoners there, knew it presently, and made a most horrible and diabolical Lamentation, crying out that it was their Queens head. Now here it is to be observed, that God himself by his own hand, brought this enemy to destruction. For in that place, where the last year, she furnished *Philip* with Canooes for his men, she her self could not meet with a Canoo, but venturing over the River upon a Raft, that brake under her, so that she was drowned, just before the English found her. Surely *Philips* turn will be next.

In his prophecy, at least, the gloating Mather was correct: within the week, Philip was killed by an ally of the English from Wetamo's town of Pocasset. The commander of the English forces ordered Philip's body to be drawn and quartered, the head being sent to Plymouth, where it was displayed on a pole for more than twenty years. Philip's wife (Wetamo's sister) was sent into slavery in the West Indies, as was their young son, a decision made after considerable debate among the Puritan clerics, some of whom cited scriptural precedents in recommending that the boy receive the punishment of execution for his father's treason.

Numerous other Algonquian leaders and warriors were executed in August and September, and armed resistance soon ended. The colonies moved to recoup the heavy costs of the war, first, by appropriating Algonquian lands and, second, by selling captives in West Indian or European slave markets. The enslaved Algonquians included about four hundred who surrendered near the end of the war with the expectation of leniency; still other captives were sold to colonists as indentured servants. The remaining New England Algonquians either fled to Canada or were settled on small reservations. As costly as the war had been for the English—about six hundred colonists died, some forty more were captured, and perhaps twenty frontier towns were destroyed—the price pales in comparison with the Algonquian losses: three to five thousand people were killed or captured, at least a thousand were enslaved, and the few who remained at liberty were deprived of their fertile homelands and dispersed.

To the victors belonged not only the spoils but also the symbols of the war. Captivity became the primary metaphor for conveying the tragedy of King Philip's War, but the hundreds of Algonquian captives, such as Philip's wife and son—who were indentured or sold into slavery—were forgotten. Rather, it was the ordeal of Mary Rowlandson that came to epitomize the meaning of the war and, by extension, to legitimize all violence against Indians. As a vulnerable gentlewoman in the hands of a ferocious heathen, Mary Rowlandson personified the settlers' fear that colonial "civility" and "godliness" would be overcome by the "savagery" of the American wilderness and its native inhabitants.

In the years following the publication of the Rowlandson narrative, the theme of captivity became a conventional way to contrast white civilization with Indian barbarism. Narratives describing actual and fictional captivity became a popular and distinctively American genre, which was realized in visual form in drawings, paintings, and sculpture. As the frontier moved westward there were significant variations upon the theme: tales took on a secular character and sometimes featured a heroic rescuer, a male captive, or even an acculturated captive. The most typical, however, resembled Greenough's sculpture, taking their power from contrasting a white female captive to an Indian male captor.

The complexity of captivity on the frontier—where Indians, too, were captives and the captors included women such as Wetamo—was reduced to stereotypes that sharply divide civility and savagery, aggression and vulnerability, along the lines of ethnicity and gender. *The Rescue,* a prominent example of this deceptive iconography, was removed from the United States Capitol in 1958, but similar images remain enshrined in other public monuments, as well as in the folklore, drama, art, and literature of popular American culture. □

The Sense and Nonsense of Edward Lear

est known for his limericks and verse, Lear was also a versatile portrayer of natural and unnatural history

y Vivien Noakes

Edward Lear was described by one of his contemporaries as a man of versatile and original genius." He was an rnithological draftsman, compared in his own time with udubon; a superb landscape artist; a traveler and musician; nd the creator of a genre of children's writing in which, as lonsense poet, he stands supreme.

It is not only his versatility that is extraordinary but also his roductivity. When Lear died he left at least seven thousand atercolors made on his travels; about two thousand studio atercolors, including the sets of illustrations to Tennyson's oems; more than three hundred oil paintings, which vary in size rom six inches to fifteen feet; two books of natural history lustrations; more than a hundred additional published rnithological lithographs; six travel books and five or six travel anuscripts prepared for publication; four books of Nonsense; a ozen published songs; extensive diaries; and several thousand elightful letters.

Born in 1812, the twentieth of twenty-one children, Lear was rought up by his sister Ann. He began to earn his living at the ge of sixteen, making "uncommon queer shop-sketches—elling them for prices varying from ninepence to four shillings: olouring prints, screens, fans; awhile making morbid disease rawings for hospitals and certain doctors of physic." In 1828 or 829 he became an ornithological draftsman, publishing his first ook, *Illustrations of the Family of Psittacidae, or Parrots,* when he was nineteen years old. The format of this book, and

Lear's bold style of drawing, set a new pattern of ornithological work that was to be followed with great success by others, particularly John Gould. Perhaps the most important part of his contribution was his insistence on drawing from living birds rather than from stuffed skins. This made his task difficult but resulted in more truthful representations, both anatomically and in the characteristics of the birds he portrayed. In 1831 Lear was invited by Lord Stanley, heir to the earl of Derby, to make drawings of the animals and birds in his menagerie at Knowsley Hall, just outside Liverpool. There Lear mixed with "half the fine people of the day," establishing a network of patronage on which he was to depend for the rest of his life.

By the time he was twenty-five he had abandoned his ornithological career to become a landscape painter. His next ten years were spent in Rome, a city that at the time attracted artists from all over Europe, with an English community that was prepared to buy and commission paintings. During these Roman years, between 1837 and 1848, Lear progressed steadily and found a ready market for his work. He returned to England twice—in 1841 and 1845–6. In 1841 he published a book of lithographs, *Views in Rome and its Environs,* and in 1846 his first travel book, *Illustrated Excursions in Italy,* appeared. In 1849 he returned to England, where he planned to settle permanently.

Lear's strength lay particularly in two areas of draftsmanship: in his ornithological work and in the best of the many thousands of landscape drawings made on his travels. Lear himself said, "I am certain, whatever good I may get by 'colour from nature' I get more by pencil," and it was in his drawing rather than in his use of paint that he built up form. This can be seen most clearly in his travel drawings, but these works were not offered for sale. Lear regarded them as his working capital, the basis of his oil paintings and what he described as his finished watercolors.

As for his work in Nonsense, Lear wrote that it "is the breath of my nostrils." It was inseparable from his life and expresses both his merriment and his most deeply held beliefs.

Lear was a man of courage not only in his travels through remote and difficult countryside but more particularly in his constant struggle to overcome the constraints imposed upon him by epilepsy, with the isolation and loneliness it brought. "Alas! Alas! how fearful a birthright was mine," he wrote in the last

ır of his life. "I wonder if others suffer similarly? Yet I dare
ask or endeavour to know." Living at a time when sufferers
m epilepsy were still considered social outcasts, Lear told no
e of his disease.

Lear's first epileptic attack came when he was five or six.
ɔm the age of seven he also suffered bouts of acute depression.
he earliest of all the morbidnesses I can recollect must have
en about 1819—when my Father took me to a field near
ghgate, where was a rural performance of gymnastic clowns
and a band. The music was good,—at least it attracted
:—and the sunset and twilight I remember as if yesterday.
ıd I can recollect crying half the night after all the small
iety broke up—and also suffering for days at the memory of
e past scene." It was some years before Lear discovered a way
which he could re-create this clownish gaiety himself; he did
through his Nonsense, and in particular his limericks.

Understanding the constraints of his epilepsy, Lear observed
ıer forces in Victorian society that destroyed the fullness of
ing. The most pervasive of these, one whose influence spread
ɔward through society as the century progressed, was the
angelical church of the time, with its inordinate emphasis on
ı and damnation. To strict evangelical Christians, life
esented many dangers. If they wished to achieve salvation—
ıd the alternative was too terrible to contemplate—they must
ny those aspects of their humanity that were sent to beguile
em back into their essential sinfulness. The human will, a
monstration of pride, must be broken. The body, the
ıremitting occasion for sin, must be curbed of all excess; the
easures of food and dress, of song and dance, laughter and play
ere vanities of the world that must be denied. Such denial
egan in earliest childhood, when joy was synonymous with
vity, and merriment was a step along the broad road to
estruction.

From this anxious narrowness, where hypocrisy might parade
virtue, there could grow a harsh intolerance. For Lear, aware
ways of his own shortcomings, human failures were less to be
ɔndemned than to be understood. His ideal of Christianity was
ı plain worship of God, and perpetual endeavour at progress."
When will it please God to knock Religion on the head and
ıbstitute charity, love and common sense?" he asked. In a
orld of distorted values he longed to see hypocrisy replaced by

Trustees of The Victoria and Albert Museum

Palaeornis melanorhynchus *(? Parakeet), 1835*

honesty, intolerance by charity, ostentation by simplicity, misery by merriment. "My dear child, I'm sure we shall be allowed to laugh in Heaven!" he reassured a small girl.

In his limericks, Lear offered children, to an extent difficult for us now to imagine, the liberation of unaffected high spirits. With a simplicity endorsed by a drawing, the short verse sets the scene and tells the story. The whole—the verse and the drawing—constitutes a clownish act, and the two parts are inseparable. Here are grown-ups doing silly things, the kind of things grown-ups never do. They jump and leap and spin, unabashed both by their unseemly abandon and the sheer folly of what they are doing. They play on crude, rustic instruments and dance hornpipes and jigs, they dress in huge bonnets and wigs, they eat and drink vastly, they are immense and immoderate, strange and impulsive. The limericks do not deceive but share with the children the reality of the human characteristics they display; for all their incongruity, the limericks have a truth that is lacking in the improving literature of the time. In an age when children were loaded with shame, Lear attempted to free them from it. By facing both the good and the bad without criticism, he gave them an opportunity to come affectionately to terms with both themselves and other people.

In Lear's Nonsense songs, the message of tolerance and understanding was joined by another: the excitement of opening one's eyes and exploring the world around, of discovering undreamed-of lands and wonders not only unseen but scarcely even imagined. For Lear, travel was more than a search for paintable views, important though that was. Brought up as a sickly child, he faced hardships in often harsh and unwelcoming countries that drew forth unknown abilities and powers. The strange, more primitive ways of life he observed, and the magnificent grandeur of many remote places scarcely ever visited by foreigners, made him realize the rewards that might come from taking adventurous risks. In a process of self-discovery, which greater caution would have made impossible, he demonstrated to himself that his life need not be ruled by his epilepsy; he saw that, for all its suffering, the world was full of beauty and wonder. Above all, he found in these journeys a physical and spiritual freedom he had never imagined possible and which he sought to share in his Nonsense songs.

Hoard from the Golden Mound

by Walter A. Fairservis, Jr.

The death of Alexander of Macedon in 323 B.C. precipitated the dissolution of an empire that stretched from the Mediterranean Sea to the Indus River. Bactria, a province of that empire, then became an independent state ruled by the Greek and Macedonian descendants of the garrisons left there on Alexander's trek to India. This Bactrian state (now encompassed by a portion of Soviet central Asia and the western part of northern Afghanistan) survived into the first century B.C. Control of Bactria then passed to a number of other peoples. Chief among these rulers were the Kushans, central Asian pastoral nomads who invaded India from bases in Bactria and elsewhere. The Kushans were dominant in central Asia at the same time the Roman Empire reached its height in the West.

For centuries Bactria lay athwart many of the trade routes critical to the commerce of Asia. Indeed, no other area of Asia has been exposed to as many different cultural influences, coming from so many directions. Later Bactrian Greeks were Buddhists, for example, and the fall of their state was due in part to Parthian Persians and central Asian nomads. The Kushans were descendants of the Yüeh-Chi, a pastoral group in close contact with the Han Chinese.

Because the history of post-Alexandrian events in this remote area is sketchy—based as it is on passing references in ancient texts, coins, and legends—archeological research in Bactria is especially important. French, British, Italian, and American missions have from time to time conducted research in Bactria. But because some Bactrian sites are in their country and others are in Afghan areas controlled by their armed forces, Soviet archeologists have been able to conduct the season-to-season digs necessary for substantial results—producing perhaps the only silver lining after five dark years of warfare in Afghanistan. Numerous reports on Soviet archeology in Bactriana have been published, but mainly in Russian journals inaccessible to the general public in the West. This present volume is therefore all the more welcome.

In 1969, a Soviet team headed by Victor Sarianidi—an exuberant, conscientious archeologist well known for his work

"Bactrian Aphrodite" in gold

on numerous sites in Soviet central Asia—came upon a low mound known locally as Tillya Tepe in the vicinity of the city of Shibarghan. The northern Afghanistan plain is strewn with such mounds, most of them dating from late periods in the history of Bactriana. Tillya Tepe, however, had surface remains indicating earlier dates—as early indeed as the first millennium B.C. Unable to begin work at the site, the Soviet team waited until the following season only to find on their return that much of Tillya Tepe was being destroyed to provide earthen material for a new highway nearby. Their protests saved about one half of the site, but archeological work did not begin until 1978. The results have been astounding.

PANTHEON

Bracelets with antelope design

Six burials dating approximately from the first century A.D., the zenith of Kushan power in these regions, were found in the ruins of a fortified temple of an earlier origin. The excavators speculate that the burials, five of them of women, were of the nobility of the nearby ancient city of Yemshi, perhaps even of the rulers of that Kushan city. The graves were vertical shafts with lidless wooden coffins set at the bottom, most of which were wrapped in clot shrouds decorated with hundreds of gol and silver disks. The graves were the boarded over and dirt was shoveled on top leaving no trace of what was beneath Eventually the board covers collapsed crushing the mortuary contents below Careful excavation, however, revealed treasure trove of the art of the heirs of th Greco-Bactrian world.

Garnet and turquoise necklace

The dead were buried in funerary thes of extraordinary richness. Al-ugh the cloth had long since disap-ared, the abundant ornamentation de it possible to reconstruct much of original dress. The existence of hems, eves, and so forth could be ascertained many cases by the position of the origi-ly attached ornaments—a complex d often frustrating labor. These orna-nts—plaques, beads, rosettes, and ban-s—along with the personal belongings the deceased that were placed in the aves, reveal the sumptuousness of the ssessions of the Kushan elite.

The Golden Hoard of Bactria is a mag-ficent presentation of these mortuary ds, which have changed the name of the e from Tillya Tepe to the Golden ound. Its 166 full-page color illustra-ns; its definitive catalog of the finds, il-strated by black-and-white photo-aphs; and its running narrative of the cavation make this volume one of the chest art tomes I have seen.

The art styles reflect the many tradi-ns of central Asia. Indian, Greek, Ira-an, and Chinese motifs are readily per-ptible, but perhaps most interesting is e influence of the animal art style of the astoral nomads of central Asia. This style as found much earlier in the Scythian, unnish, and other cultures that once ominated the heart of Asia. As Sarianidi roperly points out, the infusion of this astoral style gives life to an art that was st becoming static, as the hybrid tradi-ons from which it derived lost their vigor. n some cases, the plethora of gold, silver, nd inlaid semiprecious stones cannot dis-uise some crudeness of execution and atness of expression, characteristic of ose periods of aesthetic history in which he demonstration of wealth takes prece-ence over taste and creativity. However, turn of the page belies these thoughts nd reveals a near masterpiece.

An estimated twenty thousand objects vere recovered at the Golden Mound—the naterial and aesthetic expression of a pe-iod in central Asian history that still re-nains somewhat of a mystery to us, for we know little of the culture that motivated his wealth. But this wonderful book in-vites speculation about a vanished way of ife and about a region of the world that is now closed, alas, to western travelers.

Walter A. Fairservis, Jr., is a research associate in the Department of Anthropology at the American Museum and professor of anthropology at Vassar College. He was director of the First and Second Afghan Expeditions for the American Museum.

INDIA·FESTIVAL
India is the experience of a lifetime. It's a colorful festival where you can take an elephant that's a taxi. Climb the mighty Himalayas. Discover 5,000 years of culture, tradition, architecture and art. India is also a place where you'll enjoy modern air-conditioned hotels, excellent transportation, and people who speak English and who want to see you. See the Festival of India in the United States. Then come see the festival that is India itself.

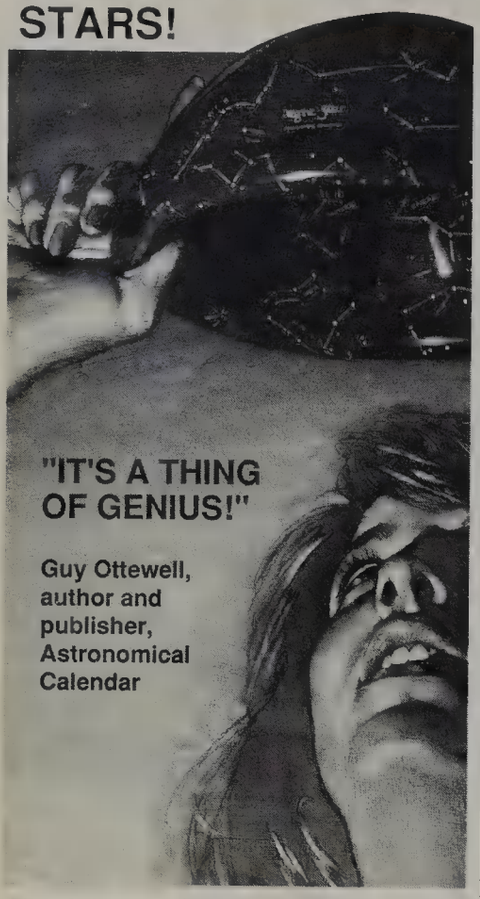
THERE'S SOMETHING NEW UNDER THE STARS!



NightStar®

At last. A lightweight star map that goes everywhere *you* go! **NightStar** is the only domed star-finder affording you an *undistorted* view of the heavens from *anywhere* on Planet Earth! **NightStar's** patented sliding flexible surface adjusts instantly for any location, time or date! The secret lies in a slippery oil film, sealed within this high quality *four-color* star-hemisphere. Durable & compact (just 8" across, yet equal in area to a 20"x10" flat map!) **NightStar** lets you follow the stars, planets (*and* Comet Halley) as never before! After viewing an early prototype of **NightStar**, the late R. Buckminster Fuller wrote:

"I am deeply impressed with the excellence of your pocket planetarium. I have very many astro-aides, enough to have made me feel at once the significance of your beautifully designed product."

Included with **NightStar** are a 60 page 'step by step' handbook (which includes a brief chapter for children), Time Dial and Latitude Finder *plus* Planet & Comet Halley Finders - all handsomely packaged. Price $44.00 plus shipping & handling: U.S and Canada $3.50; foreign $7 surface, $14 by air. *California residents add 6% sales tax.* Please remit by $U.S. check or money order.

VISA and **MASTERCARD** welcome; please call (408) 462-1049, Monday-Friday 9am-5pm Pacific Time.

NightStar makes a wonderful gift! At your request, we will ship to the person you specify and forward your receipt to you.

Early to Rise

by Thomas D. Nicholson

Four planets are in the morning sky this month but none can be easily seen. Three (Mercury, Venus, and Saturn) are too near the sun, rising in the morning twilight and transiting the sky mostly in daylight. The fourth, Mars, rises about 2:30 A.M. Although quite high in the southeast before dawn, Mars is still very far from the earth and thus very dim. Since conjunction with the sun last July, Mars has brightened by less than half a magnitude, remaining inconspicuous near Spica in Virgo. It will still be several months before the promise of the morning planets becomes a reality. And before that, even Jupiter will join them in relative obscurity.

For now, Jupiter remains an evening star, though reduced to only a few hours above the horizon in dark skies. These waning weeks of its evening cycle, however, are among the most interesting. Jupiter is very bright, outshining every star in the night sky. It appears in the dwindling twilight of the southwest on December nights, less than an hour after sundown, and remains in the sky for a while, glimmering in the fading sunlight. These circumstances also make one of the prettiest of all evening scenes: a slender crescent moon joining a bright planet. That takes place this month on the evenings of the 14th and 15th when the moon brackets Jupiter from one night to the next. Unfortunately, the moon doesn't move close enough to the planet to create the kind of scene that poets immortalize.

The following events are given in local time unless otherwise noted.

December 1: A waning gibbous moon is up at dusk, in Cancer, but virtually in line with Pollux and Castor, the twin stars of Gemini. Watch closely after dark and you should notice the moon drift slowly away from Pollux to the left (east).

December 2: Mars has been moving slowly to the east through Virgo since October, toward the constellation's brighte star Spica. It slips past Spica today, an should be visible just above the bright sta before dawn this morning. The plane moves into Libra late in the month.

December 3–4: The waning moon is i Leo, to the right of its brightest star, Regu lus, on the 3d, and to the left on the 4t Regulus and the circular group of sta above it make up a backward questio mark, forming the head and front half o the lion.

December 5: Last-quarter moon (4:0 A.M., EST) is still in Leo but near its hin quarters and tail (the triangle above an left of the moon). Venus passes Saturn (passed Mercury on the 3d) but the planet rise too late in the morning to be visible

December 6–8: The crescent moon is i Virgo when it rises each morning, and th bright star below it is Spica. It passes th star and Mars on the 8th.

December 8: The moon occults (covers Mars this morning. The event can be see over parts of North America. Mars disap pears behind the moon's bright limb whil the two are below the horizon, but th planet reappears after it rises along th east coast of the United States, about 4:1 A.M., EST. The time varies slightly with lo cation.

December 9: This morning is probably the last chance to see the waning crescen moon in the sunrise glow in Libra. Spica i above it.

December 10: The moon is at perige (nearest the earth).

December 11: The moon is new at 7:54 P.M., EST, only 24 hours after perigee The close-in moon primes both the time and the height of the spring tide, causing tomorrow morning's high tide to be higher and earlier than usual.

December 14: The second-best meteor shower of the year, the Geminids, is at maximum today. The early morning hours, when the sky is moonless, are the

Celestial Events

est time for viewing. You may see up to 0 meteors per hour after 1:00 A.M. on the 4th and 15th, but they are usually not as right as the meteors of that paragon of howers, the Perseids.

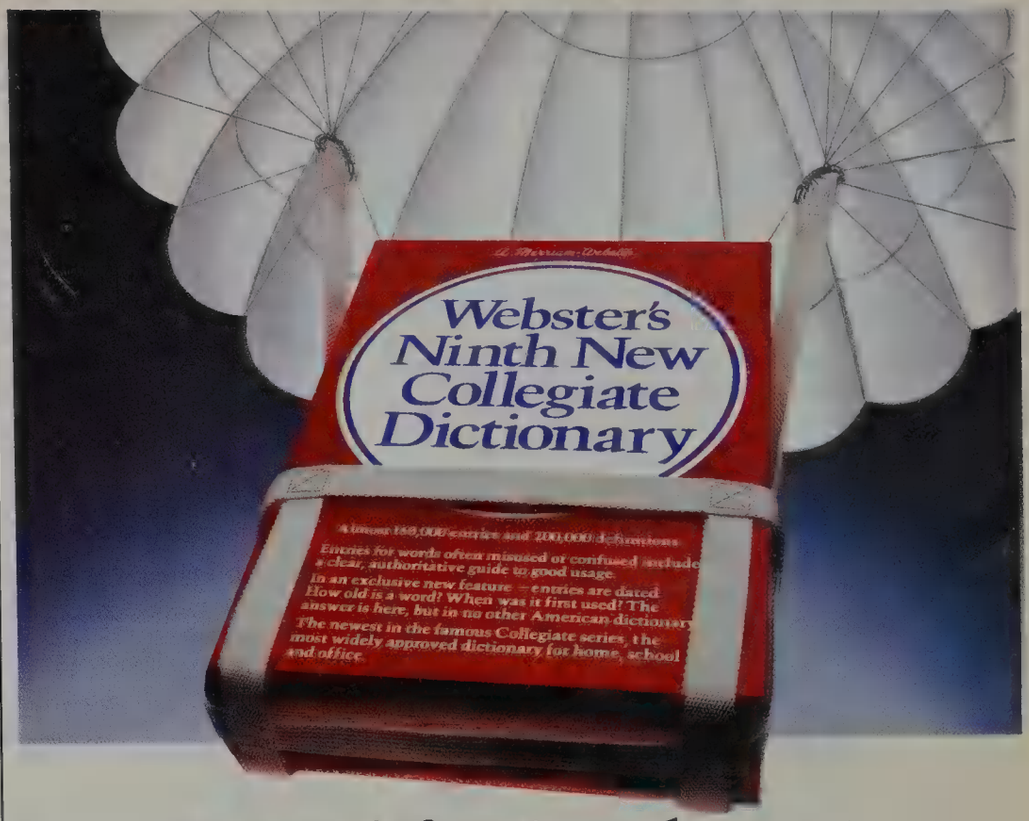
December 13–16: The chances of see-ng the thin, waxing moon are poor on the 3th, but good on the 14th. Night by ight, the moon appears higher in the eve-ing twilight and stays up later. It is below upiter until the 15th and then is higher han the planet.

December 16: Too bad we can't see Mercury and Saturn in the morning sky. Mercury passes Saturn, only a moon's di-ameter away, just about when it is at its greatest westerly elongation (to the sun's right). This morning, Mercury is actually brighter than Saturn and becomes even brighter during the rest of December. But celestial geometry is against us: the plan-ets rise too late in the morning twilight to make an appearance.

December 18: First-quarter moon (8:58 P.M., EST) is in Pisces. Because it has gone one-quarter of the way around the sun from the time of new moon, and the sun is at the winter solstice, we should see the moon near the vernal equinox. Indeed, the eastern edge of the Square of Pegasus is just above the moon tonight, and its two stars point downward very close to the ver-nal equinox.

December 21: The sun reaches the win-ter solstice, a point in Sagittarius along the ecliptic (the sun's apparent path through the stars) 23.5 degrees south of the equa-torial plane, at 5:08 P.M., EST, and the winter season begins in the Northern Hemisphere. The earliest sunset of the year occurred on December 8, however, and the latest sunrise will be on January 4.

December 22: The Ursid (named for Ursa Major) meteor shower is at maxi-mum with no moon in the morning. Not very productive (15 meteors per hour), but nonetheless something to see.



America's favorite to the rescue.

HALLEY'S COMET TOURS

Join Museum scientists on outstanding tours at the best times and locations for viewing Halley's Comet.

Australia - Halley's Comet and Wildlife Adventure: April 5-19, 1986
A world famous Australian ski resort is our base for viewing Halley's Comet at the peak of its visibility. Other highlights include national parks with kangaroos, koalas, penguins and deluxe accommodations at Heron Island on the Great Barrier Reef. $3,471 per person including round-trip airfare from San Francisco.

Trinidad & Tobago - Halley's Comet & Wildlife Adventure: April 11-20, 1986
Tobago's exquisite Arnos Vale beach resort is our base for viewing Halley's at the peak of its visibility. Enjoy swimming and snorkeling amidst exquisite coral reefs, and superb birding in Trinidad. $1,895 per person including round-trip airfare from Miami.

December 23–25: Taurus is host to the fattening gibbous moon, moving out of Aries on the 23d, close to the Pleiades; swinging past the Hyades and Aldebaran on the 24th; and nestling between the Bull's horns on the 25th. On the 24th Jupiter makes a handsome Christmas star, low in the southwest at dusk. Too bad all that moonlight's there. It won't bother Jupiter, but it does add to the problems of finding Halley's comet, a dim, fuzzy object, without much of a tail yet, above Jupiter in Aquarius, just about on the equatorial plane.

December 27: Full moon (at 2:30 A.M., EST) in Gemini, above the twin stars (Pollux and Castor). Tomorrow night at the same hour, it rises with the twins, in line with them below Pollux, just about where it was at the beginning of December.

December 30–31: The moon is back in Leo again to end the month, rising well after sundown, riding up the eastern sky with the Lion in the late evening.

Halley's Comeback

Comet Halley entered the realm of the inner planets at the end of November when it moved inside the orbital distance of Mars, about 140 million miles from the sun. It moves out again when it passes the orbit of Mars in late April 1986, on its way out of the inner solar system. Our opportunity to see it is limited to that interval. What are our chances?

If we consider all the possibilities that can result from the way in which the orbits of the comet and the earth interact, they are not very good. As a matter of fact, they couldn't be worse. If we had to pick just one of Comet Halley's 29 known returns to see, we certainly chose a bad one. From all accounts, the visit of A.D. 837 was the best. The comet then passed within 4 million miles of the earth, displayed a tail that must have stretched halfway across the sky, and had a coma that was probably bright enough to be seen in daylight—and certainly in twilight.

The visit in 1910 was also one of the good ones, even though the earth didn't come nearly as close as it did in 837 and on other visits. However, the comet was *much* closer to the sun when earth passed by in 1910, and that can add a great deal to its appearance. I'm afraid that the written and oral tradition (and the photos) remaining from that relatively recent event have built up expectations that the 1985/86 event cannot possibly realize. Nevertheless, no matter how unfavorable things may be, this is our one shot at Comet Halley, the only chance most of us will have of seeing it. The following guide summarizes what these chances may be over the next five months.

December 1985: Comet Halley is a binocular object in good position for viewing in the evening sky from the Northern Hemisphere. Moving through Pisces, south of Pegasus (see map), it should be very easy to locate in relation to the bright stars of Pegasus above it, from dusk until it sets at least several hours later. Early December is best; the brightening moon shows up during the latter part of the month. The comet resembles a fuzzy star, drifting slowly to the right in the field of stars around it, with little or no evidence of a tail. After the middle of December, the moon (full on the 27th) will interfere with viewing.

January 1986: The best opportunity for Northern Hemisphere viewers will be in the first two weeks. The comet is low in the southeast at dusk, setting within a few hours, but there will be no moonlight in the early evening hours until mid-month. The comet is brighter than it was in December, technically bright enough for naked-eye viewing under ideal conditions, but binoculars are probably necessary in most circumstances. It brightens slowly during January, but after mid-month it is too low at sunset and sets before dark. In any case, light from the waxing moon will interfere after the 10th or 12th.

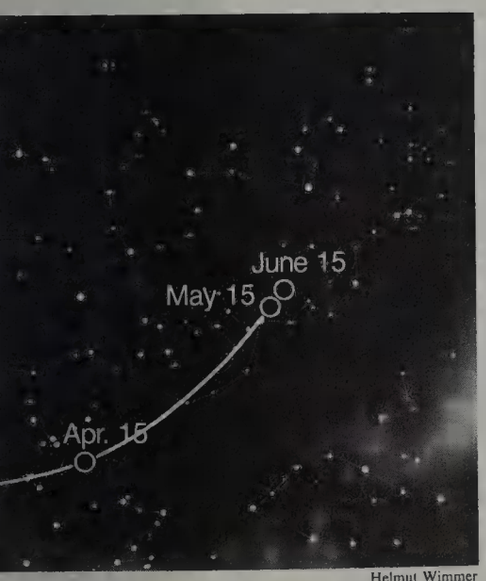
February 1986: The comet is lost from view all month because it is virtually in the same direction as the sun, above the horizon only in twilight and daylight. On February 9 it passes nearest to the sun (perihelion), about 54 million miles distant. Toward the end of the month it comes up in the east at just about dawn for Southern Hemisphere viewers; it is at its brightest and has its longest tail, but it is too low to be seen easily before the sky brightens.

March 1986: The view of Comet Halley's tail should be at its best. But everything favors southerly viewing locations. The comet is now well south of the equatorial plane and moving southward. It is a morning object, coming up before dawn. Toward the end of the month it moves through the easily recognized stars of Sagittarius, and mornings will be dark until the full moon approaches on the 26th. At latitude 40° north, there is virtually no chance of seeing the comet before morning twilight brightens the sky, but conditions improve farther south. It is definitely

th looking for from latitude 30° north
l southward. Below the equator it
uld be possible to see the comet's tail in
morning sky, a dim cloud of brightness
nting downward toward the east from
early morning hours until daybreak.

April 1986: The closest approach of the
rth to the comet on April 11 (39 million
les) gives us the brightest view in dark
urs, and morning skies are again dark.
then the tail will probably have shrunk
d the comet will have dimmed as its dis-
nce from the sun increases. It is strictly a
uthern sky object, too low for anyone
ove latitude 20° north to see but offer-
g Southern Hemisphere viewers the best
portunity of the whole show from about
pril 1 until the 15th. After that, the
met quickly swings into the evening sky
it slips between the earth and the sun.
hen it emerges in late April to the sun's
ft, it will be moving away rapidly, dim-
ing and shrinking again. But it is moving
rth again as well, giving northern view-
s with binoculars another shot at the
met as it fades.

May 1986: If you haven't seen Comet
alley by now, you will probably have to
ait until A.D. 2061. The view will proba-
y be better then.



Helmut Wimmer

The diagram, above, traces Halley's ath from left to right as it moves across he sky. The circles and dates indicate here the comet will be on the fifteenth of ach month until June 1986, when it will ave completed its journey around the un. The comet will continue to fade from iew, returning to interplanetary space.

The enlargement at right gives the ex- ct dates for the comet's positions as it asses through the stars of Pegasus and Aquarius. This map will be updated each nonth to let you know where Halley's omet will appear.

600 MILES AND 4,000 YEARS INTO HISTORY.

Cruise the Nile with an educated eye.

Timeless yet ever changing, ancient yet modern, Egypt presents a paradox worthy of the Sphinx itself.

On a Swan Nile Cruise, the greatest monuments of man's existence come alive within your reach, as you explore the wonders of this legendary land.

From Cairo to Assuan you will be accompanied by a guest lecturer, an expert whose informed but informal talks will blow the dust off the centuries and put into context the places you will be visiting.

Choose from over 20 Nile Cruise departures. And Swan Hellenic offers a choice between all-inclusive packages or cruise only rates.

To find out more, see your Travel Agent, or write Exprinter for a free color brochure.

And join us for a journey into the past that will surely become the experience of your lifetime.

Leon Sinks, Florida

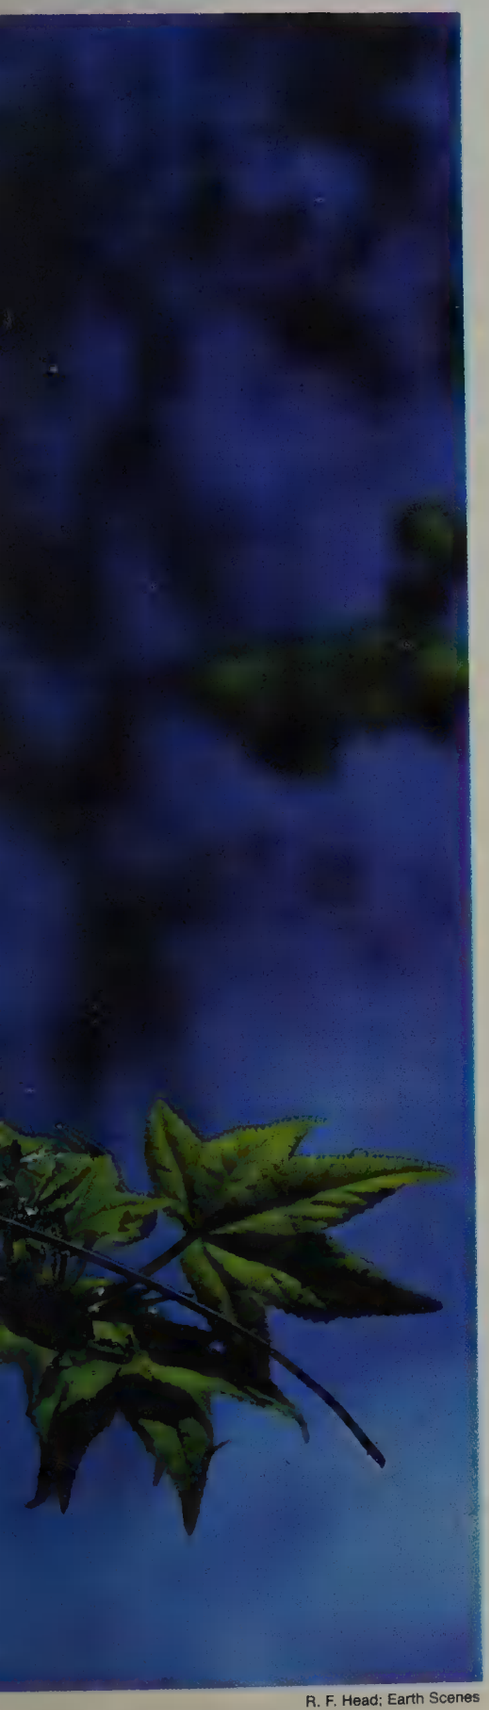
by Robert H. Mohlenbrock

The low hills of sandy, red clay that surround Tallahassee, Florida, drop off to the delta plains a few miles south of the city. To the casual observer, the plains, which slope gently for almost twenty miles to the Gulf of Mexico, seem a monotonous sea of sand that supports large numbers of longleaf pines and little else. But there are some surprises beneath the surface. Under the loose quartz sands is a bed of easily dissolved limestone. The abundant rains that fall in this humid, subtropical region (an average of fifty-seven inches annually) trickle through the permeable sands into this underlying layer. Percolating ground water dissolves the limestone, rapidly lowering parts of the terrain. The resultant depressions, or sinks, pock the landscape. Shallower sinks are filled with sand, but deeper ones often accumulate water.

A cluster of water-filled sinks perforate the sandy plains in the Apalachicola National Forest at the southern edge of Leon County and are known collectively as the Leon Sinks. A circular route that follows an old sand road for about a mile and a half passes by the five major sinks in the Leon Sinks Geological Area. Each sink has its own distinctive feature. Hammock Sink is a large, circular depression that drops sixty-five feet from the surrounding pinelands. Its basin, filled with clear, turquoise blue water, reflects the silhouettes of some of the surrounding trees. Black Sink is a funnel-shaped depression that drops into a deep, dark abyss. Gopher Sink, a cavernous hole lined with rocks, takes its name from its vague resemblance to a den inhabited by gopher tortoises. Natural Bridge Sink includes a tree-covered limestone bridge. Fisher Creek runs beneath the bridge and disappears underground, only to resurface 150 feet away.

Dismal Sink is the most impressive of the Leon Sinks. Two hundred feet from rim to rim, it drops abruptly seventy-five feet to a dark pool of unknown depth. For twenty feet above the water surface, the sheer, dripping walls are of solid rock. Handsome ferns, whose roots somehow have found narrow crevices in the rock,

Sweet gum is a southern hardwood species.



R. F. Head; Earth Scenes

display their feathery fronds above the water. There is no safe way to descend into Dismal Sink, and extreme care should be taken even when walking near its rim.

The abundant water in the sinks nourishes a community of plants that contrasts with the surrounding drier pinelands. Where the steep slopes of the sink are permanently moist, large specimens of laurel oak, water oak, white oak, southern magnolia, sweet gum, American beech, basswood, sweet bay, and sour gum may be found. On somewhat drier slopes, the dominant trees are mockernut and pignut hickories, red oak, and persimmon. These species, known collectively as southern mixed hardwoods, are found over much of the southeastern United States but are unexpected in the sandy coastal plains of Florida's Panhandle. Beneath the hardwoods is a layer of shrubs that consists of two gnarled members of the heath family, farkleberry and squaw huckleberry; a yellow-flowered shrub known as horse sugar; and small, symmetrical dogwoods. An entanglement of creepers often makes hiking difficult, while at ground level are wildflowers not found in the sandy surroundings.

The hike from one sink to the next takes the visitor through a different world of sand and sand-tolerant species. The relatively nonorganic, unconsolidated quartz sand primarily supports a sparse forest of longleaf pine and blackjack and turkey oaks. The pines may approach one hundred feet in height, but the oaks grow more slowly and seldom reach twenty feet. The herbaceous undergrowth is sparse, and large patches of sand remain exposed to the sun. Colonies of bracken fern, which can prosper under adverse conditions, give a false hope that the sand community can support lush vegetation.

Longleaf pine, whose mature needles are up to fifteen inches long, is well adapted to grow in the often deep sand of the coastal plain. It is found from North Carolina, around peninsular Florida, and over to eastern Texas, skipping only the Florida Keys, the Everglades, and the bottomland woods adjacent to the Mississippi River. For the first six years of its life, while its roots are developing, the young longleaf pine looks like a mounded clump of bright green grass. Its main bud remains level with the ground, where it forms long needles in dense clusters. When the little tree is about seven years old, however, it loses its grasslike appearance and begins a rapid upward growth, which continues until the tree begins to decline in vigor after three or four hundred years. Under optimal growing conditions, a longleaf pine may attain a height of 120 feet and have a trunk diameter of nearly 3 feet.

Because it cannot tolerate shade, the longleaf pine does not withstand competition from other trees, including others of its kind. The roots of a mature longleaf pine radiate for a distance of fifty to one hundred feet beneath the tree, and seedling longleaf pines that germinate within this radius survive only a short time. As a result, trees in a stand of longleaf pines are widely spaced. Considerable sunlight penetrates to the sandy ground between the trees, providing an ideal situation for the growth of wiregrass.

Fred Whitehead; Earth Scenes

A longleaf pine germinates.

100% Merino Wool Mattress Pad

MANUFACTURER DIRECT

Soft *100% Merino Wool cushions and cradles your body for a deeper, more restful night's sleep. Even the best mattress creates pressure points on the shoulders, hips and back. Soft, thick Merino Wool conforms to the contours of your body, relieving pressure points. Many people report they fall asleep faster and enjoy a more restful sleep.*

Wool *is a natural insulator. In winter, the pad retains body heat to keep you warm. In summer, the pad keeps you cool by absorbing moisture.*

As *an exclusive and superior design innovation, we have eliminated the standard elastic straps and have designed the pad like a fitted bottom sheet to hold the wool more firmly in place.*

The *Wool Bureau has given this product the Superwash® designation. It can be machine washed and retain its original softness, resiliency and durability. Non-allergenic. Does not itch.*

In *an independent study of our wool pad conducted by the University of Wisconsin, 83% of the participants reported a better night's sleep.*

If *you don't enjoy the best night's sleep you've ever had, simply return the pad for a complete refund. Delivery: We ship within 24 to 48 hrs.*

The wiregrass and the millions of pine needles that fall to the sand provide rapid-burning fuel for surface fires. Lightning frequently ignites such fires, which burn over wide areas of the pine community. One reason for the longleaf pine's success is that it is the most fire-resistant tree in the eastern United States. In the early growth stage, the dense cluster of needles protects the terminal bud from fire damage. Once the thick, flaky bark has formed on the trunk, the tree resists hot fires as if it had a covering of asbestos. In an experiment at Florida State University, a slab of bark from a mature longleaf pine was exposed to an acetylene torch for one minute. A thermometer placed on the side away from the flame registered only a three degree rise in temperature, and there was little damage to the bark.

The branches of the longleaf pine, unlike those of many other pines, are widely spaced, often giving the tree an appearance of spindliness. If the lower branches of a longleaf pine should ignite, the fire usually cannot advance to the branches above. The wide separation of the trees makes it unlikely that fire could spread from the crown of one tree to another.

The success of the longleaf pine actually depends on fire because periodic fires kill young saplings of other trees that might eventually provide competition. In addition, longleaf pine cones fall to the sandy ground unopened, and only a s ing fire will cause them to open. In way, seeds are liberated under the most vorable conditions. The tree's depende on fire was suggested as early as 1847 the British geologist Sir Charles Ly who observed this species on a visit to A bama. Several ecologists believe tha fire were kept out of a longleaf pine st long enough, many of the trees that r only line the limestone sinks would ger nate there and eventually choke out shade-intolerant pines, ultimately form a continuous community of south mixed hardwood species.

"This Land" highlights the biologi phenomena of the 153 U.S. national f ests. Robert H. Mohlenbrock is dis guished professor of botany at South Illinois University at Carbondale.

Brontosaurus's Asian Cousin

On the cavernous second floor of the iseum's Roosevelt Rotunda are casts of o dinosaurs, put on display this past Oc- er. One, known as *Mamenchisaurus,* is enty-two feet long and eleven and one- f feet high at the shoulders. Its neck, rty-five feet in length, is the longest of y dinosaur ever discovered. It must ve weighed fifty tons when alive. The ier, a duck-billed dinosaur known as *intaosaurus,* stands eighteen feet tall d stretches twenty-three feet from the of its duck bill to the end of its tail. eager compared with *Mamenchisau- s, Tsintaosaurus* probably weighed out three tons. Both are the only exam- es of their kind, and are two of the most portant dinosaur skeletons ever found China.

A petroleum exploration team discov- ed the *Mamenchisaurus* in 1957 at amenchi, in Sichuan Province, western hina. The nearly complete skeleton (only e tip of its tail is missing) was excavated the Sichuan Provincial Museum, and e bones were taken to the Institute of ertebrate Paleontology and Paleoanthro- logy in Beijing. There they were care- lly chiseled from their rocky matrix, and e skeleton was then mounted for perma- nt display.

The *Mamenchisaurus* had been identi- ed and named as early as 1954 by Dr. hung-Chien Young, who is known as the ther of Chinese paleontology. Basing his ndings on the isolated bones of several in- viduals, Dr. Young had determined that *Iamenchisaurus* was a distinct species of uropod, giant plant-eating dinosaurs at flourished during the Upper Jurassic eriod (155–140 million years ago), when nosaurs were the dominant animals on nd. This new skeleton, though, was the rst—and subsequently the only—*Ma- enchisaurus* complete enough to be ounted.

A field party from the Institute of Pa- ontology discovered the *Tsintaosaurus* 1951, in Tsintao, Shandong Province, ong the eastern Chinese coast. The skel- on, also extraordinarily complete, was ken back to Beijing, where it was named nd prepared for exhibit by Dr. Young in 958. The *Tsintaosaurus* skeleton repre- sented another distinct species, a duck- billed dinosaur, or hadrosaur, that lived during the Upper Cretaceous period (95–65 million years ago), immediately preceding the extinction of the dinosaurs.

Until early in this decade, these dinosaurs were known to the West only through illustrations and scientific papers published by Dr. Young. But following the normalization of diplomatic relations between China and the United States in 1979, scientific contacts with Western-bloc nations increased, and in 1982 arrangements were made to bring these skeletons to Australia for a special exhibit.

As part of the exchange agreement, the Australians agreed to make polyurethane replicas of the dinosaur skeletons. Because the cost of prospecting for new dinosaurs is so high, and the chances of finding

Mamenchisaurus *is installed in the Rotunda.*

any specific species are so low, replicas of existing specimens are often made by one institution for another. The completeness of the *Mamenchisaurus* and the *Tsintaosaurus* made them excellent subjects. The work was done at the National Museum of Victoria in Melbourne, where a display hall was closed and converted to a workshop. Under the combined supervision of the museum's preparators and vertebrate paleontologists, rubber and plastic molds were made of each bone, and the polyurethane poured into these molds. Once the polyurethane hardened, the new "bone" was removed and colored to make it indistinguishable from the original. The process took several days for each bone, and more than three months for an entire skeleton. (Both *Mamenchisaurus* and *Tsintaosaurus* are composed of more than two hundred bones.)

Four casts were made of each of the two dinosaurs. One set was returned to China with the skeletons, and the second was kept by the Australians. The last two sets were offered for sale to the American Museum of Natural History and the Los Angeles County Museum of Natural History, at a price of $100,000 per set. The Los Angeles museum, which at the time was preparing a new dinosaur hall, bought one set, and the American Museum entered into negotiations for the other. In the meantime, the American Museum has borrowed Los Angeles's casts and has deferred a final decision on purchasing a set of its own.

If the American Museum decides to buy the two casts, they will join the world's largest collection of dinosaurs, one that is being continually expanded. The collection includes several skeletons found in North America that are relatives of the Chinese finds. During the time of the dinosaurs, the earth's present continents were connected in one great land mass known as Pangaea. The climate across this supercontinent was almost uniformly tropical and subtropical. The parallel conditions evidently caused the dinosaurs to coevolve, and related species are often discovered in areas now separated by oceans and thousand of miles of land.

Mamenchisaurus was closely related to and resembled the Museum's own *Brontosaurus* (more correctly called *Apatosaurus*), on display in the center of the Hall of Early Dinosaurs. *Mamenchisaurus* probably behaved much like *Brontosaurus*. It walked on all fours, and probably waded through the ponds of its swampy environment, either to keep its enormous body cool or to relieve it of the strain of its tremendous weight. Its cranelike neck may have enabled it to reach for soft leaves at the tops of giant fern trees, but this particular sauropod seems less suited than others to this mode of foraging. In many sauropods, the neck meets the body at an angle, facilitating its reaching ability. In the *Mamenchisaurus*, a rather rigidly constructed neck extends almost horizontally from the body, implying a certain lack of flexibility.

Tsintaosaurus, which lived some sixty million years later, was related to the numerous duck-billed dinosaurs that fill the Museum's Hall of Late Dinosaurs. The hadrosaurs probably also lived near water, and standing erect on their hind legs, they used their duck bills and four, clawed fingers to collect pine needles, cycad fronds, and any other available plant material. Besides ducklike bills, projections atop skull, in the shape of spikes, ridges, or low crests, characterize the hadrosa On *Tsintaosaurus*, this projection is a gle bony spike pointed forward. The sp may have been a weapon, a sexual disp or perhaps, covered with flesh when dinosaur was alive, a resonating cham allowing *Tsintaosaurus* to fill the la scape of late Cretaceous China with de sonorous tones.

The *Mamenchisaurus* and *Tsintaos rus* replicas will be on display in the M seum until January 6. Then they wil dismantled, packed in crates, and ship to Los Angeles, where they will be pla on permanent display.

Marshall Schwartz

At the American Museum

Seasons in the Sky

As live baroque music fills the Hayden Planetarium's Sky Theater, crystal-clear night skies, laser effects, and images of the seasons will flash upon the dome. *The Four Seasons*, on Wednesday, December 11, at 7:00 and 9:00 P.M., will feature Bach's Concerto no. 5 in F Major and Vivaldi's *The Four Seasons*. Tickets are $6.00 for members, and $9.00 for nonmembers, and must be ordered in advance. For additional information call (212) 873-1327.

Native American Film Festival

The six films in this year's free festival focus on diverse aspects of Native American life, such as dance styles throughout North America, the Hopi-Navajo land dispute, indigenous rights, and Venezuelan Indians who live on the edge of a geographic and cultural frontier. The festival will be held on December 14, and begins at 10:15 A.M. with a screening of Alan Lomax's *Rhythm of the Earth*. The final film, Connie Poten and Pamela Robert's *Contrary Warriors: A Story of the Crow Tribe*, begins at 4:45 P.M. All films will be shown in the Kaufmann Theater. For additional information call (212) 873-1300, ext. 559.

Who Gives a Toot?

On Sunday, December 15, at 3:00 P.M. the Bloomingdale Chamber Orchestra will present a free musical concert designed to appeal to young people. The program will take place in the Kaufmann Theater and includes works by Alexander Bizet, Edvard Grieg, and others. A special feature is Joe Szerly as Tubby the Tuba. For additional i formation call (212) 873-1300, ext. 55

Kwanzaa

Kwanzaa is a unique Afro-America holiday dedicated to the African ance try of present-day black Americans. It celebrated from December 26 throug January 1. The Museum will pay tribu to Kwanzaa by celebrating Seed Da Elders Day, and Regeneration Day, December 28, 29, and 30, respectivel Free programs, cosponsored by the Ed cation Department and the New Yo Urban Coalition, will take place in se eral areas of the Museum. For detai call (212) 873-1300, ext. 514.

The Star of Christmas

This holiday Sky Show, at the Ha den Planetarium through January takes viewers back in time nearly 2,00 years to view the skies of the first Chris mas. The show explores astronomic and mythological mysteries such as th "star" that led the three wise men fro the East to Bethlehem. For time an ticket information call the Planetariu at (212) 873-8828.

Courses for Stargazers

The Hayden Planetarium's course begin in early January. Topics this se son include the mysteries of Halley comet, life beyond the earth, planetar weather, navigation, aviation, the sola system, and more. For a free brochur please call (212) 873-1300, ext. 206 write: American Museum-Hayden Pla etarium, 81st Street at Central Par West, New York, N. Y. 10024.

MBERS-
W YORK
EKEND

NEW YORK, NATURALLY!

(Designed exclusively for Members of the American Museum of Natural History)

Whether your first love is art or archaeology, elegance or evolution, Tiffany or Tyrannosaurus rex, the stars of the heavens or the stars of Broadway, you'll find it in our Members' New York Weekend. For three exciting days and two wonderful nights, a great city and a great Museum will be all yours.

- **Two nights in one of New York's finest hotels:** Stay at The Waldorf Astoria, The Parker Meridien, or The Plaza. Minutes away from New York's famed theater, shopping, and eating districts and only a short ride away from the Museum itself.
- **Two complimentary meals:** Enjoy a full breakfast at your hotel and a leisurely lunch in the Museum's charming greenhouse-style restaurant.
- **The Official Guide and a Highlights Tour:** As soon as you make your reservations, we will send you the Museum's Official Guide to introduce you to our fabulous treasures. And when you arrive at the Museum, take a Highlights Tour, which provides fascinating insights into the Museum's most popular halls. Or savor the Museum at your own pace. Journey through halls filled with gems, dinosaurs, myriad life forms, and peoples from all over the world. The Star of India sapphire, wolves hunting in the night, ancient totems of the Northwest Coast, and Mayan sculptures are just a few of the Museum's varied wonders. At the end of your visit, relax in our private Members' Lounge or take advantage of your Members' discounts at Museum gift shops.
- **Special Exhibitions:** The Museum presents an exciting schedule of special exhibitions throughout the year.
- **Free Planetarium and Naturemax Tickets:** Journey through the heavens in the Planetarium's famed sky theater and enjoy the film experience of a lifetime at Naturemax, with its movie screen sixty feet wide and over four stories high.
- **Personalized Service:** The Members' Service Desk will help customize your weekend to suit your needs and tastes. They'll be glad to arrange theater or concert tickets, reservations at New York's top restaurants, a carriage ride through Central Park, or tours of the town.
- **Discount air fares:** Special rates are available on American Airlines, the official airline of the Members' New York Weekend.

Tour Program Price: $92.50 per person, per night. Tax included. Based on two nights double occupancy. Rates also available for families and individuals.

Tofu or Not Tofu

Is it nobler to consume bean curd or to eat meat in a protein-deficient world?

by Raymond Sokolov

While most of us weren't watching, the soybean multiplied in the fields of the Corn Belt and became America's third cash crop after corn and marijuana. Indeed, this country now produces three-quarters of the world's supply of this Asian legume. This is all the more remarkable because the vast majority of Americans know nothing or almost nothing about soybeans.

The reason is brutally simple. By and large, soy products do not show up on our tables in a form easily identifiable as soy. In fact, some effort is usually made to disguise *Glycine max* as something else. This practice goes back at least as far as World War II, when soy-based margarine came on the market as an ersatz butter that had to fight for fair treatment in markets against stiff lobbying and discriminatory laws fomented by the dairy industry.

So the national soy crop grew quietly, but it grew. Oil pressed from soybeans crept anonymously onto shelves where corn and peanut oil had previously dominated—and it surpassed them in sales, although most consumers did not realize that they were opting for a soy product over more "American" salad oils and many still don't. They know, however, that the price of soy oil is attractive, even though they may continue to think that the main culinary use of soybeans is to produce exotic soy sauce, which actually is a fermented form of soy meal and a source of protein in Asian cuisines.

Protein is the key word in any informed discussion of soybeans. They are a spectacular source of protein, five times richer than corn. And their amino acid makeup is dazzlingly close to that of meat (unlike most grains or legumes, which have to be mixed or supplemented to insure the necessary amount of complete protein in a nonmeat diet). None of this valuable soy protein makes its way into soy oil. Very little of it, in any form, is eaten by people in this country. Instead, we feed it to animals and then eat them. To a vocal minority of intelligent and well-meaning folk, this is shocking. While the Third World totters from malnutrition and African children's hair turns red before they die from the protein deficiency called kwashiorkor, we cast mountains of soy protein before swine and other livestock.

I will not bore you with a recitation of the embarrassing inefficiencies and wastefulness of our meat-centered cuisine. For at least twenty years, we have all been exposed to the highly cogent arguments of ecological zealots, such as Frances Moore Lappe, who want to maximize world agricultural resources. They make the irrefragable point that soy and other vegetable protein sources are the frugal, sensible route to nutritional sufficiency for all human beings.

Unfortunately, logic has run up against the most dismal of obstacles, the human factor. On the one hand, it has proved very difficult to spread food, even surplus food, among hungry nations. Politics, economics, and the physical difficulties of distribution all work against the best impulses of agriculturally successful nations, of which we are the surpassing example.

Even when donated food does reach needy populations, it is often a mixed blessing. They have accustomed themselves over generations to other staples and do not take easily to what we send. Ethiopia is a tragic example of international food charity barking its shins against an ingrained local food preference. As I wrote in the September issue, it is requiring the force of a totalitarian regime to induce starving Ethiopians to eat donated sorghum instead of the vanishing grain called teff that is a linchpin of their culture.

No one in this culture should scoff at the Ethiopians for this apparently suici stance. Food preference is a deep-sea conviction, especially in a traditional ture. And we Americans, superfici quick to latch on to new food fads, h only to consider our collective lack of thusiasm for soy protein foods to sym thize with the culinary "recalcitrance" the Ethiopians.

If logic could prevail in such matt we would have long ago abandoned steak and burger for soybean curd. Th pure white, delicate little cakes, of called tofu (the Japanese form of th original Chinese name, *doufu*), are an most ideal protein source. They are che they are free of cholesterol, and they ar neutral in taste that they go with alm any other food or flavoring. What is mo they are widely available, not just health-food stores, but in supermark And an evangelical literature has spru up to educate a carnivorous and reacti ary populace in the mysteries of tofu.

This preaching has won an impress number of converts. *The Book of Tofu*, William Shurtless and Akiko Aoyagi (T Speed Press, Berkeley), had sold 340,0 copies when it went back to press in 19 according to information on its cover. T same authors have also written guides other soy products, the fermented flav ing miso, and the cultured Indones "soyfood" tempeh.

It is tofu, however, that enjoys the w est acceptance in American life, to point where a soy-based, ice cream a logue called Tofutti is now compet with yogurt. But so far as I can see, products in any identifiable form are likely to cure us of our addiction to spa ribs or even cornbread.

I say this while absolutely doting on tofu dishes I have come to know in C nese restaurants. Perhaps the greatest i Szechuan specialty called *mapo doufu*.

this fiery preparation, mushrooms, ground meat, and water chestnuts, as well as the typical spices of Szechuan, all enliven the cool and modest medium of bean curd.

Bean curd cuisine in China is a large subject. There is deep-fried bean curd and fermented bean curd and bean curd sheets—all prepared with a multiplicity of sauces and garnishes.

Once you begin reading about bean curd, you wonder how you could ever have thought it was a limited and intrinsically boring food. Its possibilities have been exhaustively worked out over centuries, especially in Japan, and they are, in concept, as diverse and enticing as the European repertory for chicken.

Just opening *The Book of Tofu* at random, I have come across several pages of recipes for bean curd cut into pouches and stuffed with everything from salad to sophisticated mixtures of mushroom, bamboo shoots, noodles, and quail eggs. There is smoked tofu, tofu diced in soup or in sukiyaki, and on and on.

Each stage of the basic process of making tofu out of soybeans has generated entire categories of foods. The whole beans can be eaten after soaking and boiling, roasted, or ground into flour. But in tofu process, beans are soaked overn and then ground, usually with more wa A blender does an ideal job. This puré called *go* in Japanese. It is useless as a tein source unless cooked, because beans contain a substance that inhibits enzyme trypsin and thus prevents di tion of soy protein. When this mas brought to a boil, it separates into a w "milk" and a fibrous, sawdustlike stance called *okara*. In American hea food stores, you will find frozen *okara* ties and also various forms of soy m Seasonings and potato made the patti tried reasonably palatable. A carton "Soy Moo" was flavored with ho which was the only detectable flavo the drink.

In standard tofu making, the *okar* strained out of the milk. Then, very m as rennet or other curdling agents added to mammal milk in cheesemak to cause the curds to coagulate out of whey, the tofumaker stirs a salt or an a into soy milk. For the most part, gyps (calcium sulfate) or Epsom salts (mag

Spicy Bean Curd

(Slightly adapted from *Chinese Meatless Cooking*, by Stella Lau Fessler. Plume, 1981)

- 3 squares fresh soft bean curd
- 2 tablespoons oil
- 1 teaspoon minced ginger
- 3 tablespoons chopped scallion
- 1 tablespoon Szechuan hot bean paste
- 1 tablespoon soy sauce
- ½ teaspoon salt
- ½ teaspoon sugar
- ½ cup stock
- 1½ teaspoons cornstarch dissolved in 2 tablespoons water
- 1 teaspoon sesame oil
- ¼ teaspoon Szechuan peppercorn powder (see note)

1. Rinse bean curd and drain. Cut into 1-inch-square pieces.
2. Set a wok (or skillet) over high heat and add oil. When oil is hot (and gives off a wisp of smoke), stir in ginger and 2 tablespoons scallion and cook for 20 seconds. Add hot bean paste and bean curd. With a spatula, stir bean curd very gently.
3. Add soy sauce, salt, sugar, and stock and bring to a full boil. Thicken sauce with dissolved cornstarch, then add sesame oil and peppercorn powder.
4. Immediately transfer everything from the wok (or skillet) to a serving platter. Sprinkle with remaining scallion and serve.

Yield: Two to four servings, depending o other dishes

Note: To produce powder, toast 3 tabl spoons of whole Szechuan peppercorns a dry skillet over medium heat for about minutes. Grind with mortar and pestl then sift through a strainer.

Shira Ae

(Slightly adapted from *At Home with Japanese Cooking*, by Elizabeth Andoh Knopf, 1980)

This thick white dressing looks som thing like cottage cheese and, Mrs. Ando suggests, can be used to stuff tomatoes. will keep under refrigeration, covered, f a day or two.

- ½ bean curd cake (about 6 ounces)
- 1¼ teaspoons superfine sugar
- Pinch of salt
- Drop of soy sauce (preferably *us kuchi shoyu*)
- ½ teaspoon sake (rice wine)

1. Boil the bean curd in water to cover f 2 to 3 minutes and then drain it in cloth-lined colander. Gathering up th edges of the cloth to make a bag, twi and squeeze to wring out all exce moisture.
2. Mash the bean curd before seasonin it with the remaining ingredients.

Yield: Two-thirds of a cup

sulfate) are the solidifiers in modern

ıe solidifiers cause tofu curds to pre-
ate out of hot soy milk. The curds
like little white flecks in a sea of clear
ɔw whey. Aficionados try to use as lit-
ɔlidifier as possible in order to produce
most delicate curds.

ɔ make standard tofu, you then strain
the whey and let the curds drain in a
nder or perforated mold until they set-
nto a delicate white cake.

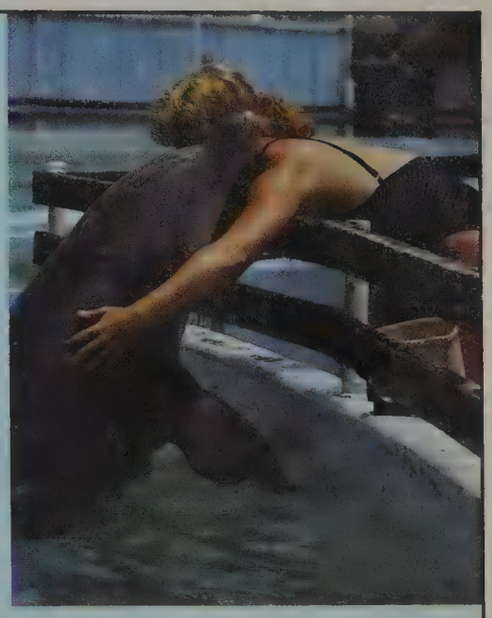
did all this, and I will say that it
ded a most delicate, soft tofu, better
ı I can buy even in oriental groceries.
tofu tasted just like all the earlier
ges in the process. It had no better fla-
than the milk or the *okara* or even the
ey. In other words, it tasted very bland,
ch blander than unsweetened oatmeal.
it did have a splendid texture. And ac-
ding to figures in *The Book of Tofu,* it
tained 73.5 percent of the original pro-
ı in the soybeans, in an attractive, com-
t cake that could be stored in water
te easily.

liked my tofu. I even ate some plain,
h moderate pleasure. But I liked the
a of it and the look of it much more
n I enjoyed it as a food in the mouth. At
t, I am willing to eat it only occasion-
in dishes that combine it with other,
orously flavored ingredients. No doubt
s means that I am hopelessly culture
ınd, a boor by Japanese standards, a
gish carnivore in a protein-poor world.
Frankly, I wouldn't have it any other
y. Food *is* culture bound, and aren't we
ky that it is. Our taste in food helps us
ine ourselves, helps make us feel at
me, and offers a ritual of familiar plea-
e in a world largely drained of ritual.
eat may be wasteful, but thrift and the
ional use of resources are not the only
tues in the world. The best policy in ag-
ulture is the one that attempts to supply
ople with as much of what they want as
humanly possible. A world resigned to
tting its protein from sensible, pure tofu
uld be a world that has given up on
easure as most people define pleasure.
en in Japan, young children think of
fu as something that is good for them,
e spinach for American children.

No one is ever going to persuade most
nericans that tofu can be more than an
casional diversion from normal food. A
end of mine, eager to try a new taste
eat, recently bit into a piece of deep-
ed tofu and said: "It's like French-fried
thing."

*aymond Sokolov is a writer with a spe-
al interest in the history and prepara-
on of food.*

PLEASE TOUCH



Now you can make a hands-on contribution to important studies happening all over the world.

In the next twelve months Earthwatch will help scholars and scientists launch over 90 research expeditions to remote locations. They will be solving some fascinating problems in animal behavior, ecology, archaeology, and cultural preservation.

You can join them.

Two- to three-week teams are now forming. All you need is common sense, a desire to help, and a sense of humor. We teach you the rest.

Submarine Cuisine

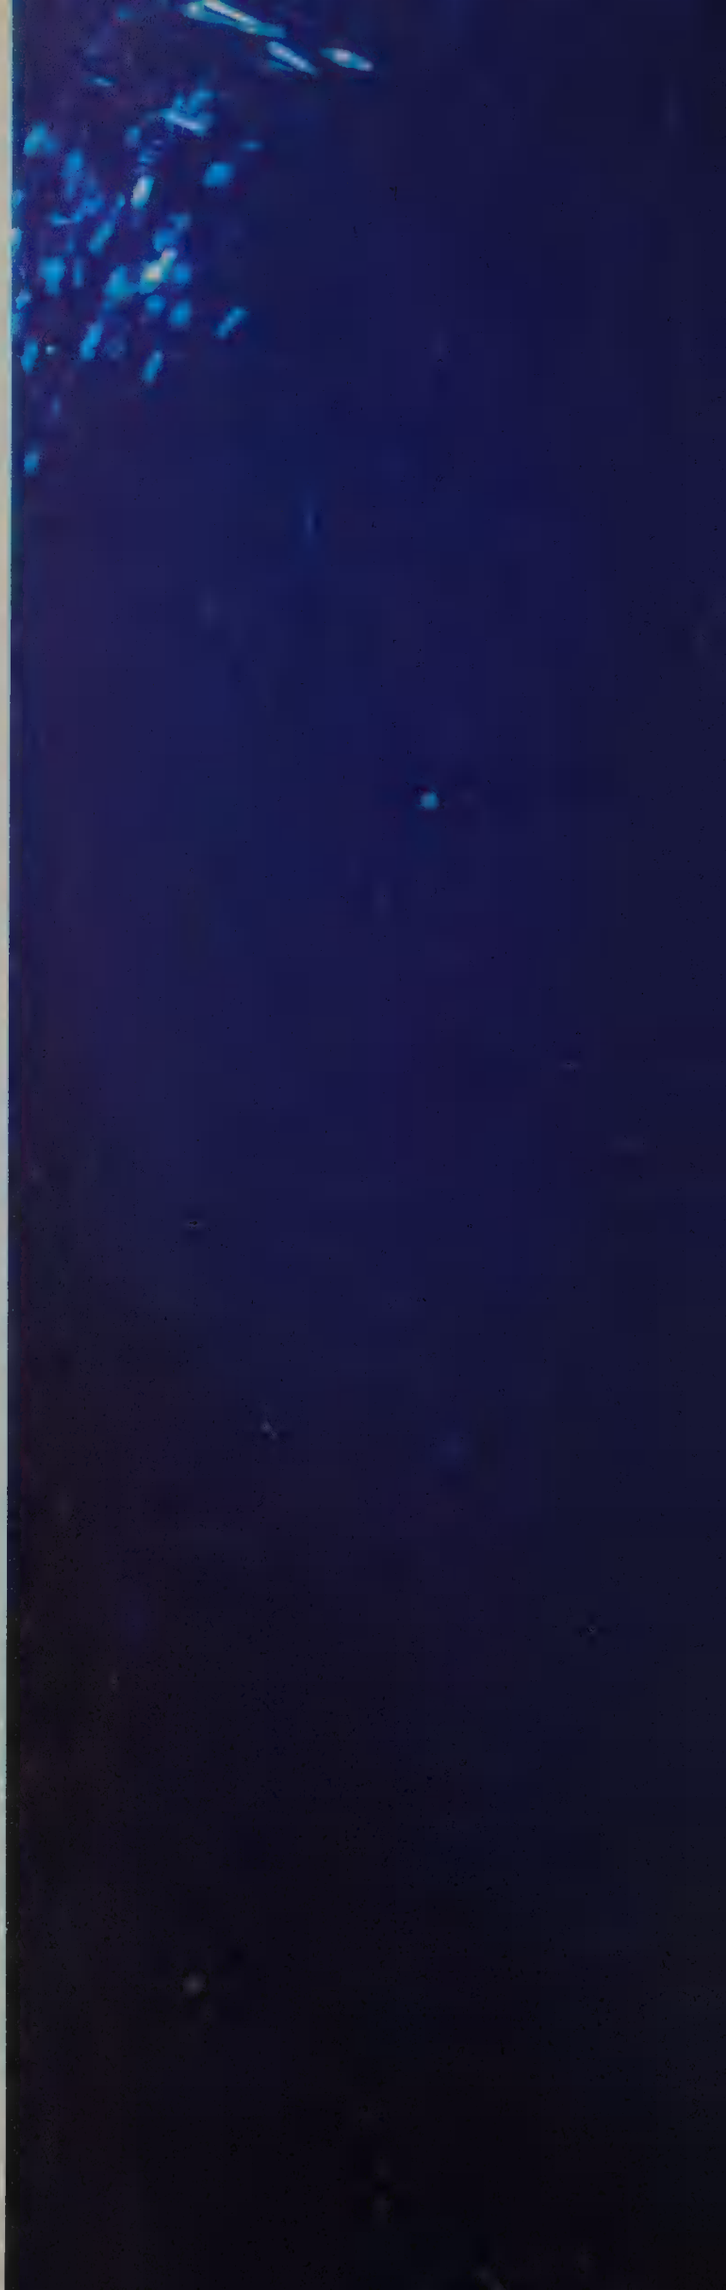
The southern tip of Baja California is the place people call Land's End and it's a pretty unceremonious ending. It's mostly rock: cliffs drop seventy feet to water and there's no beach to speak of. But below the surface the wall of rock continues, descending perhaps another sixty feet to the floor of the Sea of Cortez. This place, where the sea begins, is a lot livelier, at least from the photographer's point of view. Lots of sea lions paw around through the surf, and manta rays, big flat-headed creatures, frequently jet by. There are enormous schools of bait fish, and as naturalist-photographer Doc White learned one day last winter, there are cormorants down there too, taking the bait.

Cormorants, which are related to pelicans, anhingas, and other seaworthy birds of the order Pelecaniformes, fish for a living. They eat fish, crabs, squids, and some amphibian larvae. And they are excellent divers, partly because their bodies are well adapted to swimming underwater and their feathers are water permeable, which reduces buoyancy. Cormorants have been known to swallow stones to help themselves gain depth. In fact, cormorants are so good at fishing that people in some parts of Africa and Asia use them as hunters. They tie a collar around the bird's neck so that it can't swallow. Then they let it loose on a long leash, the bird dives, and when it surfaces, they take the fish out of its mouth.

Doc White was diving and photographing off Land's End when he noticed this cormorant tracking schools of fish. One thing that intrigued him about its technique was that the bird seemed to pick out one fish from the crowd and concentrate on it. White's impression was that this helped the bird avoid being distracted by the quick, glittery maneuverings of the larger mass of fish. Whenever it caught a fish, the cormorant swam up to the surface to eat it. A few minutes later, the photographer was rejoined by the hunter and the hunt continued.

Unlike a bird, a naturalist-photographer doesn't find out the results of a hunt right away, so it wasn't for another day or two that Doc White found out just what he had caught: a dark bird pointed at a fish cloud just beyond Land's End.

Photograph by Doc White



Learn German On Your Own!

Not just a phrasebook, but a *real* language course! More than 21 hours of recorded material make this unique self-instructional cassette/book course a truly effective way to learn German.

The course consists of a series of cassettes recorded by *native* German speakers, and accompanying textbook. You'll learn to speak German the way you learned English – by listening and repeating. It's easy, and takes only 25 minutes a day. Your cassette player becomes your "teaching machine." You learn where and when you want to, and at your own pace.

The course was developed by the Foreign Service Institute to train U.S. State Department personnel. In addition, it has been used successfully by thousands of our mail-order customers.

Packaged in handsome vinyl binders, the course is available in two parts. Order either, or save 10% by ordering both:

☐ **Volume I: Basic.** 10 cassettes (13 hr.) and 647-p. text, $135.

☐ **Volume II: Intermediate.** 8 cassettes (8 hr.) and 179-p. text, $120.

(CT residents add sales tax)

Phone orders call toll-free: **1-800-243-1234**

To order by mail, clip this ad and send with your name and address, and a check or money order – or charge to your credit card (VISA, MasterCard, AmEx, Diners) by enclosing card number, expiration date, and your signature.

Try it for 3 weeks at no risk — we promise prompt refund if not completely satisfied. We offer courses in 42 languages; send for free catalog.

Additional Reading

Burgess Shale (p. 34)

The Burgess Shale, by Harry B. Whittington (New Haven: Yale University Press, 1985), is a comprehensive and fully illustrated account of this great paleontological find. Whittington, a leading authority on the Shale's fauna, summarizes what is currently known about these ancient fossils: how they came to be so perfectly preserved, how new reconstructions of the animals have been made, and what their lives were like. "The Animals of the Burgess Shale," by Whittington and Simon Conway Morris (*Scientific American,* July 1979, pp. 122–33), describes the Burgess Shale fauna and reconstructs the underwater environment these organisms inhabited some 530 million years ago. Roger Lewin, a British science writer who has been associated with *New Scientist* and *Science,* is author of *Thread of Life* (Washington, D.C.: Smithsonian Books, 1982), an excellent introduction to evolution, sponsored by the Smithsonian Institution and with an introduction by Ernst Mayr. Aimed at the general public, it is easy to read and abundantly illustrated and noteworthy in this instance because it includes a good section on the Burgess Shale, "A Submarine Explosion of Forms" (pp. 106–25).

Babassu Palm (p. 40)

Two good introductions to the study of the babassu palm can be found in *Economic Botany,* a journal published by the New York Botanical Garden (Bronx, New York 10458-9980) for the Society for Economic Botany. They are "The Babassu Oil Palm of Brazil," by K.S. Markley (vol. 25, pp. 267–304), and "Subsistence Benefits from the Babassu Palm," by P.H. May et al. (vol. 39, pp. 113–29). *Harvest of the Palm,* by James J. Fox (Cambridge: Harvard University Press, 1977), discusses two islands in southeastern Indonesia with economies centered on the intensive use of the lontar palm tree. The palm's juice is the staple of the people's diet and its leaves, leafstalks, and trunks provide the wherewithal for their housing. Harol Moore, one of the world's foremost p taxonomists, contributed "Palms in Tropical Forest Ecosystems of Africa South America" to *Tropical Forest E systems in Africa and South Americ* comparative review edited by Meggers, E.S. Ayensu, and W.D. Du worth (Washington, D.C.: Smithso Institution Press, 1973).

Captive Images (p. 50)

The White Man's Indian, by Robe Berkhofer, Jr. (New York: Vintage Bo 1978), is a fascinating account of whites have stereotyped the American dian, beginning five centuries ago with lumbus's discovery of America and tinuing until today. Berkhofer shows early colonists quickly adopted a descending set of assumptions about tive peoples that pervaded almost all sequent thought about the Indian– philosophy, science, the arts, and lit ture, as well as in the policies of gov ment officials, missionaries, and soldi Richard Slotkin's *Regeneration Thro Violence* (Middletown, CT: Wesle University Press, 1973) is a literary an sis of the relations between American I ans and European-Americans from c nial times through the mid-ninetee century. Slotkin explores the approac the Indian in the writings of Co Mather, James Fenimore Cooper, other American authors, and traces the literary traditions developed f early narratives of war and captivity le the emergence of the frontier hero pers fied by Daniel Boone. *The Invasion America,* by Francis Jennings (New Y W.W. Norton and Co., 1975), a revisio history of Indian–white relations in se teenth-century colonial New England cludes a discussion of King Philip's W James L. Axtell's *The European and Indian* (Oxford: Oxford University Pr 1981), a series of essays on the intern tions of Indians and white colonists on Atlantic Seaboard, contains a numbe

ovocative articles about white captives. *ritans Among the Indians,* edited by den T. Vaughan and Edward W. Clark ambridge: Harvard University Press, 81), is a collection of actual Puritan otivity narratives, including Mary Rowdson's diary, dating to the first quarter the eighteenth century. The narratives e edited (with updated language) and notated with a good introduction. The ginal version of Rowlandson's narrative s published in a facsimile edition by rland Publishing, New York, in 1977: *e Narrative of North American Indian ptivity,* Vol. 1 (third edition), edited by ilcomb E. Washburn.

lward Lear (p. 58)

The first biography of Edward Lear s Angus Davidson's *Edward Lear: ndscape Painter and Nonsense Poet* 812–1888) (London: John Murray, 68). Among the many other books that al with Lear's life and work as a writer, ustrator, artist, musician, and traveler e: Philip Hofer's *Edward Lear* (New rk: Oxford University Press, 1962) and *dward Lear as a Landscape Draughtsan* (Cambridge: Belknap Press of Harrd University, 1967); E. Kelen's *Mr. onsense: A Life of Edward Lear* (Nashle: Thomas Nelson, 1973); John Lehann's *Edward Lear and His World* New York: Scribner's, 1977); Vivien oakes's *Edward Lear: The Life of a anderer* (London: BBC Publications, 85); S. Hyman's *Edward Lear's Birds* ondon: Weidenfeld and Nicolson, 80); and A. Thorpe's *The Birds of Edard Lear* (London: Ariel Press, 1975). ome of the well-known writers who have mmented on Lear include Aldous Huxy in *On the Margin* (London: Chatto and indus, 1923, pp. 167–72), George Orell in *Shooting an Elephant and Other ssays* (New York: Harcourt, Brace, 945, pp. 187–92), and Peter Quennell in *he Singular Preference* (London: Colns, 1952, pp. 95–101).

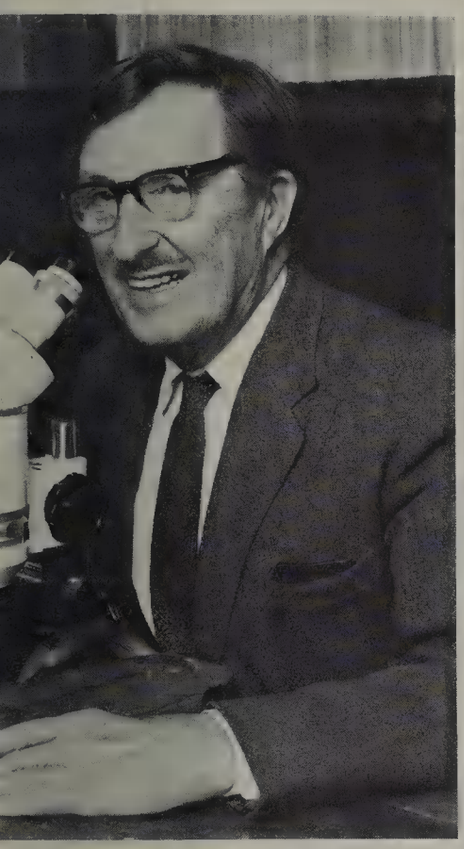
Authors

How do paleontologists reconstruct an ancient environment? To bring the Burgess Shale fossils of British Columbia to life, **Derek Briggs**, left, and **Harry Whittington** (page 34) needed the stamina of mountaineers, the exactitude of anatomists, and a blend of logic and imagination. Briggs, a lecturer in geology at the University of Bristol, England, says that the excitement of this work lies in "the discovery of animals unlike any others known, and the interpretation of their mode of life from first principles." The Burgess Shale was first investigated in the early 1900s. Coauthor Harry Whittington, who led the reinvestigation, is Emeritus Woodwardian Professor of Geology at the University of Cambridge, England. His fieldwork has been conducted virtually worldwide. Briggs, whose fieldwork has centered in the British Isles and North America, faces a new challenge: describing a group of fossilized, soft-bodied Silurian animals recently discovered in Wisconsin.



Anthony and Suely Anderson (page 0), husband and wife and coauthors, net on an airplane flight over the Ama- on River in 1975. "As recently as nine ears ago," they report, "one could fly ver vast stretches of the region and see nly a few clearings. This is no longer ossible." Their belief that "conserva- ion in this area ultimately depends on ational land management in already ettled places" led them to study ba- assu palm forests, the subject of their rticle in this issue of *Natural History*. Anthony, who earned a Ph. D. in botany t the University of Florida, has done eldwork in Central America, the An- ean countries, and eastern Amazonia. Suely has done fieldwork in both central nd eastern Amazonia. He comes origi- ally from Massachusetts; she comes rom São Paulo. With their two children, he Andersons now live in Belém, where Anthony is a researcher at the Goeldi Museum studying the Kayapo Indian ystem of forest management. Suely vorks as a translator.

ALASKAN WILDLIFE ADVENTURE

June 27 - July 14, 1986

Join Kenneth A. Chambers, Lecturer in Zoology at the American Museum, for a journey to America's last great frontier. Cruise through fabulous Glacier Bay with its whales, seals and teeming birdlife. Explore scenic Denali (Mt. McKinley) National Park and see giant moose, white mountain sheep, barren ground caribou, and golden eagles. Visit volcanic Katmai and watch brown bears fishing for salmon.

Fly to the remote Pribilof Islands, summer home to over a million fur seals and countless, rare nesting sea birds. Limited to 25 participants. For further information write to DISCOVERY TOURS, American Museum of Natural History, CPW at 79th St. NY, NY 10024, or call (212) 873-1440.

Ride up and down stairs safely.

Wecolator

Handi-Lift

Liberty Wheelchair Lift

For over fifty years, the Cheney Wecolator™ Stairway Elevator with its unique cog-drive has helped people get up and down stairs. It's designed for a wide variety of curved and straight stairways, even spirals.

The Liberty™ Stair Lifts provide safety and reliability in a space efficient design. Nobody offers a better, lower cost solution for straight stairways.

The Handi-Lift® Vertical Wheelchair Lift allows installation in confined areas, yet has a lifting range of 4 to 12 feet. Where a restrictive access is required, you'll find the Handi-Enclosure™ unsurpassed for safety and ease of installation.

The Liberty™ Wheelchair Lift adapts to straight stairways, even those with intermediate landings. With appropriate options, all Cheney products comply with ANSI A17.1.

For more information on how Cheney can help you solve access problems, write Darlene Lewis or call toll free 1-800-782-1222.

Pauline Turner Strong (page 50) says her concern with the stereotyping of social groups dates back to her student days at inner city schools in the late 1960s—a time when the nation's conscience was aroused by racial discrimination. Her scholarly interest in the subject began after college, when she worked as a research assistant to Alfonso Ortiz, an anthropologist who was documenting how fixed notions about American Indians developed. Strong became especially intrigued with the way narratives written by early American colonists taken captive by Indians influenced the creation of these stereotypes. In 1977, when she began graduate work in anthropology at the University of Chicago, she decided to delve into this topic for her dissertation. Strong is currently an instructor of anthropology at Colorado College in Colorado Springs.

Vivien Noakes (page 58), a freelan writer who lives in London, has enjoye the works of Edward Lear since chil hood. In 1963, she began to study Le professionally and in 1968 she publishe *Edward Lear: The Life of a Wandere* now in its third edition. Considered t leading authority on Lear, Noakes w guest curator for the exhibition "Edwa Lear: 1812–1888" at the Royal Aca emy of Arts in London and The Nation Academy of Design in New York Cit She hopes next to turn her attention the First World War and is at present d ing research on that subject. Any tim left over from research projects is d voted to reading, music, and her famil

Doc White (page 90), whose firs name is really Shelton, specializes in u derwater photography. He began divin for fun in 1958 and was "utterl amazed" by what he saw. Those sight led him to begin spearfishing and tha led him to take up underwater photogra phy. When he is not diving himself, h runs a charter boat service for othe divers off the southern California coas The most important characteristic fo would-be underwater photographers White says, is to be a good diver and t get to know the environment. "You'v got to get there first" before you can tak a picture. The photograph published i this month's "The Natural Moment was taken with a Nikonos II camera an a 15-mm underwater Nikkor lens.
